Inner residues of macrothiolactone in autoinducer peptides I/IV circumvent spontaneous S-to-O acyl transfer to the upstream serine residue†

Masanobu Nagano, Satoshi Ishida and Hiroaki Suga *

Autoinducing peptides I and IV (AIP-I/IV) are naturally occurring cyclic thiodepsipeptides (CTPs) bearing a Ser–Thr–Cys–Asp/Tyr (STC[D/Y]) tetrapeptide motif, where the Cys thiol (^{35}C) in the side-chain is linked to the Met C-terminal carboxylic acid (M_{COOH}) to form 5-residue macrothiolactones, $^{35}\text{C}(\text{D/Y})\text{FIM}_{\text{COO}}$. We have recently reported that CTPs containing SX_1CX_2 motifs spontaneously undergo macrolactonization to yield cyclic depsipeptides (CDPs) by an unprecedented rapid S-to-O acyl transfer to the upstream Ser hydroxyl group. Interestingly, even though the STC[D/Y] motif in AIP-I/IV is a member of the SX_1CX_2 motif family, it maintains the CTP form. This suggests that AIP-I/IV have a structural or chemical motive for avoiding such an S-to-O acyl transfer, thus retaining the CTP form intact. Here we have used genetic code reprogramming to ribosomally synthesize various AIP-I analogs and studied what the determinant is to control the formation of CTP vs. CDP products. The study revealed that a Gly substitution of the inner Asp/Tyr or Met residues in the thiolactone drastically alters the resistance to the promotion of the S-to-O acyl transfer, giving the corresponding CDP product. This suggests that the steric hindrances originating from the α -substituted sidechain in these two amino acids in the AIP-I/IV thiolactone likely play a critical role in controlling the resistance against macrolactone rearrangement to the upstream Ser residue.

Introduction

Naturally occurring peptides often possess unique macrocyclic structures and exhibit a broad spectrum of bioactivity, and thereby the discovery of such natural products has been an important mainstream in academia and the pharmaceutical industry.^{1,2} Among them, a class of macrocyclic thiodepsipeptides (CTPs) rarely exist in nature due to their chemical instability of the thiolactone bond.³ However, there are some examples of CTPs that exhibit bioactivities, *e.g.* thiocoraline⁴ and noshipeptide⁵ with anti-cancer and antibiotic activities.

Among others, autoinducing peptides (AIPs) produced by *Staphylococcus aureus* are known as a family of CTPs composed of a 2–4-residue N-terminal extotail and a 5-residue thiolactone.^{6–9} When the AIPs are secreted from cells, they interact with the cognate membrane protein receptor, referred to as accessory gene regulatory C (AgrC), to activate downstream bacterial virulence signalling, which is regulated by the local density of the extracellular AIPs, referred to as quorum sensing “autoinducers”. AIPs are ribosomally expressed as a precursor linear form, referred to as AgrD, which is composed of leader, core, and AgrB-recognition domains (Fig. 1a).

The AgrD is post-translationally thiolactonized by AgrB and further proteolyzed to the mature AIPs as side-chain-to-tail cyclized CTPs.¹⁰

We have recently discovered that when a SPCG (Ser–Pro–Cys–Gly) motif in peptides is S-acylated on the Cys’s thiol side chain upon incubation with a thioacyl donor molecule, the acyl group spontaneously transfers to the Ser’s hydroxyl side-chain *via* an S-to-O acyl transfer in a site-specific manner.^{11,12} This unprecedented chemistry led us to investigate *in vitro* ribosomal synthesis of side-chain-to-tail cyclized depsipeptides (CDPs) in one-pot, where a nascent linear peptide with a combination of an SPCG motif and a backbone thioacyl donor downstream macrothiolactonizes to form the corresponding CTP. This CTP spontaneously undergoes macrolactonization *via* S-to-O acyl transfer, yielding the corresponding CDP (Fig. 1b). During the above study, we were able to alleviate the SPCG to the SX_1CX_2 motif, where X_1 and X_2 represent nearly any amino acid, except Pro at X_2 . Most importantly, the chemistry allows us to access a broad range of CDPs in a nearly context-independent manner and with ring sizes consisting of 7–17 residues expanded from the parental 5–15 residue-ring sizes of the CTPs.

Among the known *S. aureus* AIPs, we have noticed that AIP-I and AIP-IV contain an STC(D/Y) motif belonging to the SX_1CX_2 motif family (Fig. 1a). Therefore, it is possible that the

occurrence of a similar S-to-O acyl transfer reaction in AIP-I/IV rearranges the CTP to a “chemically more stable” CDP. However, previous studies on AIP-I and their mutants including insights into their structure and activity relationship (SAR) did not report such an S-to-O acyl transfer event.^{13–15} This fact has motivated us to investigate AIP-I/IV using our one-pot ribosomal CTP/CDP synthesis approach to understand the nature of suppression of the S-to-O acyl transfer and why the CTP form can be maintained.

Results and discussion

First, we conducted a one-pot *in vitro* ribosomal synthesis of AIP-I using our genetic code reprogramming approach in place of chemical¹⁶ or intein-mediated synthesis.¹⁷ For this purpose, a mRNA template (mR1) for expression of an AIP-I analog, referred to as AIP-Ia, was designed (Fig. 2a and b). In this molecule, the thiolactone (C8–M12), STCD motif (S6–D9), and Y5 were kept as the same residues as wildtype AIP-I, whereas the N-terminal peptide sequence at the upstream position of Y5 was replaced with a short peptide (fM1–G4) to facilitate peptide analysis by MALDI-TOF MS (Fig. 2b). A thioester was directly introduced downstream by reassigning the Trp codon (UGG) with α -thio-p-chloro-phenyl lactic acid (^{HS}F^{Cl}13) using a Trp-deficient FIT (flexible *in vitro* translation) system,^{18,19} which gives an alternative route of enzymatic thioesterification using AgrB or intein, and the sequence was terminated using a following short peptide (YRA) (Fig. 2a). As expected, the expression of pre-AIP-Ia with the ^{HS}F^{Cl}13 reassignment afforded a single peak of the peptide corresponding to AIP-Ia by MALDI-TOF MS (Fig. 2c, $[M + H]^+ = 1390.72$ m/z observed), and no

Fig. 2 One-pot *in vitro* ribosomal synthesis of the AIP-I analog (AIP-Ia) without post-translational enzymes. (a) mRNA (mR1) and precursor peptide sequence (pre-AIP-Ia) used for *in vitro* CTP/CDP synthesis. 3'-Acylated tRNA, ^{HS}F^{Cl}-tRNA^{Asn#3}, was *in vitro*-prepared using a flexizyme in advance, and then used for translation in the Trp-deficient FIT system to generate a backbone thioester. f, formyl group. (e) Dethioacetylation of thiolactone by addition of cysteine.

precursor linear peptide, pre-AIP-Ia ($[M + H]^+ = 1996.75$ m/z), was detected, indicating that one-pot synthesis of AIP-Ia was achieved.

Since conversion of CTP to CDP *via* the S-to-O acyl transfer would not result in any mass difference, in order to validate the

exact form of AIP-Ia we performed post-translational modification on the peptide product in two ways. First, we treated the peptide with iodoacetamide (IAA) that could alkylate a free Cys residue present in the peptide sequence. If the thiolactone was formed, such a free Cys residue could be absent in the peptide and thereby no alkylation should occur. As expected, no alkylated product was observed by MALDI-TOF analysis, suggesting that the thiol group on Cys8 was used to form an *S*-acyl isopeptide bond (Fig. 2d). Second, the CTP form of AIP-Ia was confirmed by dethioacetylation using 10 mM of Cys. If the peptide product includes a thioester bond, Cys cleaves the bond in a manner of native chemical ligation to give the Cys adduct at the C-terminal *via* ring-opening.²⁰ In fact, the addition of Cys to the translated product promoted a mass shift by 121 Da, indicating that the corresponding Cys adduct was produced (Fig. 2e). These studies have solidly validated that the AIP-Ia has the desired thiolactone form, which does not undergo the *S*-to-*O* acyl transfer to the side chain of S6 even though it has the STCD motif.

To determine which residues are important for maintaining the CTP form, we first conducted mutations of T7 being the upstream residue adjacent to Cys8. Thus, the T7 residue (X_1 in SX_1CX_2) in the exotail part of AIP-Ia was substituted by 8 distinct amino acids (X_1 = A, Y, K, N, Q, E, G, and P in Fig. 3a and Table S1a, ESI[†]). The respective translated products and IAA-labelled products were analyzed by MALDI-TOF MS. The mass value in each peptide corresponded to the CTP form regardless of the residue at the T7 position (Fig. S1, ESI[†]). For the D9 residue (X_2) in the thiolactone ring, it was mutated to 7 distinct amino acids (X_2 = A, Y, K, N, Q, E, and G in Fig. 3b and Table S1a, ESI[†]). The mutations A, Y, K, N, Q, and E also retained the CTP form (Fig. S2, ESI[†]). Importantly, the D9Y mutant corresponds to the naturally occurring AIP-IV thiolactone, meaning that the *S*-to-*O* acyl transfer does not take place in both AIPs. In contrast, for the D9G mutant (X_2 = G), the post-translational alkylation gave a mass shifted by 57 Da, corresponding to the formation of alkylated CDP (D9G-CDP-AA in Fig. 3c and d). This implies that the single substitution of D9G in the thiolactone of AIP-Ia dramatically promotes the *S*-to-*O* acyl transfer.

To determine the ratio of CDP/CTP form in the D9G mutant, the translated product was semi-quantitatively analyzed by LC-MS. A positive control, AIP-Ia, was subjected to LC-MS, and then the extracted ion chromatogram (EIC) was evaluated. We observed no separated peak and no alkylated product using IAA (Fig. S3a, ESI[†]). On the other hand, when the same experiment was performed on D9G-CTP, the EIC chromatogram gave two peaks of 19% (11.0 min) and 81% (11.6 min), which were assigned to a D9G-CDP and a D9G-CTP, respectively (Fig. S3b, ESI[†]). Extending the translation time from 30 min to 60 min increased the CDP product from 19% to 45%, suggesting that the *S*-to-*O* acyl transfer in D9G-CTP slowly proceeded. The IAA alkylation of D9G-CDP (the peak observed at 11.0 min) afforded a fraction of D9G-CDP-AA (a peak observed at 10.5 min) in an approximately 54% yield. These results confirmed the occurrence of the *S*-to-*O* acyl transfer of the D9G mutant.

Fig. 3 Mutation study of the X_1 and X_2 positions of the SX_1CX_2 motif. (a) Mutation study of AIP-Ia at Thr7 to an X_1 residue. All the resulting translation products maintained the CTP form. (b) Mutation study at Asp9 to an X_2 residue. Only mutation to Gly facilitated *S*-to-*O* acyl transfer. The second bottom shows a structure of D9G-CDP and its MALDI-TOF MS analysis of the crude translation products, which was a mixture of CTP and CDP forms. pre-D9G, a linear precursor peptide with a D9G mutation. Potassium adduct (§), DTT adduct (2), and Cys adduct (3) were also observed. 2 and 3 are attributed to an *in vitro* translation system (see ref. 11). The bottom is a structure of alkylated D9G-CDP by IAA and its MALDI-TOF MS analysis. f, formyl group; 1a, alkylated hydrolyzed peptide; 2a, trialkylated DTT adduct; 3a, bis-alkylated Cys adduct.

Since the D9G mutation in the AIP-Ia thiolactone promoted the spontaneous rearrangement from CTP to CDP, we next performed Gly scanning of other amino residues in the thiolactone ring (F10, I11, and M12 in Table S1b, ESI[†]). Neither the F10G nor I11G mutation induced the conversion of CTP to CDP (Fig. S4a and b, ESI[†]). On the other hand, a fraction of the M12G mutant rearranged to CDP (M12G-CDP-AA in Fig. 4a and b, Fig. S4c, ESI[†]). The double G mutant at the 9th and 12th positions (D9G and M12G) underwent a major conversion to the CDP-AA (Fig. 4a and b, Fig. S4d, ESI[†]). More drastic replacement of the DFIM thiolactone sequence with GGSG (9–12GS) gave a nearly complete conversion to the CDP form (Fig. 4a and b, Fig. S4e, ESI[†]), which was consistent with our previous report.¹¹ Note that the double G mutant at the 10th and 11th positions (F10G and I11G) completely left the CTP intact (Fig. S4f and Table S1b, ESI[†]), indicating that D9 and M12 are the critical determinants for making the thiolactone resistant to the rearrangement. Likely, G mutation at the 9th or 12th position in the AIP-Ia alleviates the conformational rigidity of the thiolactone ring and reduces the steric hindrances

around the carbonyl group of the thioester, allowing for the nucleophilic attack of the hydroxyl group of S6 on the thioester bond and the formation of CDP *via* the *S*-to-*O* acyl transfer.

To this end, we further tested if the ring expansion of the 5-residue thiolactone could induce the *S*-to-*O* acyl transfer upon keeping these two key residues, D9 and M12(+X) in the ring. We thus prepared 6, 7, and 8-residue ring CTPs, where more structurally relaxed peptide sequences consisting of Gly and Ser residues were introduced between Asp9 and Met12 in the thiolactone ring (Fig. 5a and b, Fig. S5, Table S1c, ESI[†]). Interestingly, the *S*-to-*O* acyl transfer in the 6- and 7-residue ring CTPs did not occur, whereas it did occur in the 8-residue ring CTP to form a 10-residue ring CDP in approximately half of the fraction. This result suggests that D9 and M12(+2) residues in up to 7-residue thiolactone rings prohibit the *S*-to-*O* acyl transfer to the upstream Ser residue in the STCD motif, but further ring expansion very likely loosens the ring constraints to facilitate the *S*-to-*O* acyl transfer, affording the corresponding CDP.

Conclusions

We recently reported that CTPs containing an SX₁CX₂ motif spontaneously undergo macrolactonization *via* rapid *S*-to-*O* acyl transfer, yielding the corresponding CDPs. Though the naturally occurring autoinducing CTPs, AIP-I and IV, contain STCD and STCY motifs (X₁ = T and X₂ = D or Y in the SX₁CX₂ motif), respectively, we experimentally confirmed that the *S*-to-*O* acyl transfer does not take place in an AIP-I analog, leaving the CTP form intact. Taking advantage of the FIT system with genetic code reprogramming, we have prepared various mutants for the outer and inner residues of the thiolactone ring, revealing that a Gly substitution of the Asp/Tyr residue in the STC(D/Y) motif and a C-terminal Met residue (whose carboxyl group forms the thioester bond) dramatically alter the resistance to the *S*-to-*O* acyl transfer, rearranging into the CDP form. Since mutations from the Asp/Tyr residue to arbitrary amino acids other than Gly do not alter the resistance, the steric hindrances originating from the α -substituted sidechain likely play a critical role in controlling the reactivity of the thioester bond to the hydroxyl group of the upstream Ser. Moreover, the expansion of the thiolactone ring from 5 residues to 6 or 7 residues still maintains the CTP form as far as the aforementioned critical residues are kept, whereas that to 8 residues promotes the *S*-to-*O* acyl transfer, yielding the corresponding CDP consisting of the 10-residue lactone ring. We propose that not only the steric hindrance by the inner residues adjacent to the thioester bond in the thiolactone but also the ring constraints in the AIP-I/IV effectively prevent the undesired ring-expansion²¹ to CDP. Likely, the naturally occurring AIP-I/IV could have evolved to maintain the CTP scaffold by taking smaller ring-size and placing appropriate residues in the thiolactone to make the necessary interaction with the cognate receptor, AgrC.

So far, more than 40 AIPs with a thiolactone have been reported (Table S2, ESI[†]),^{9,22} and among them 8 AIPs have the

SX_1CX_2 motif in addition to the *S. aureus* AIP-I/IV described in this study. However, none of them has a Gly residue at the critical positions near the thioester bond, implying that these naturally occurring AIPs are also resistant to the *S*-to-*O* acyl transfer, *i.e.*, they maintain the CTP form. This information is useful to predict the naturally occurring thiolactone structure of AIPs,^{23–25} giving guidance for the study of the structure–activity relationship in quorum sensing modulators.^{13,26}

Experimental

Oligonucleotides

The oligonucleotides used in this study are listed in Tables S2 and S3 (ESI[†]). Reverse primers for assembling tRNA templates were modified with 2'-*O*-methylation (G(me)) at the second last nucleotide of the 5' termini to suppress non-templated nucleotide addition in *in vitro* transcription with T7 polymerase.²⁷ Standard oligonucleotides were purchased from Eurofins Genomics K.K. (Japan) and methylated oligos were purchased from Gene Design Inc. (Japan).

Preparation of flexizymes and tRNA

Flexizymes (eFx) and tRNA_{CCA}^{Pro1E2} were prepared by run-off *in vitro* transcription with T7 RNA polymerase as previously described.^{18,28}

Thioacetylation of tRNA with ^{HS}Phe^{4Cl} by flexizymes

As previously reported,¹⁹ 2 μL of 250 μM tRNA, 2 μL of 250 μM flexizyme and 2 μL of 0.5 M bicine-KOH buffer [pH 9.0] and 6 μL of deionized water were mixed and heated to 95 °C for 2 min and cooled to RT over 5 min. 4 μL of 3 M MgCl₂ was added and the mixture was transferred to an ice-bath. Finally, 4 μL of 20 mM pre-reduced ^{HS}Phe^{4Cl}-CME ester by TCEP-HCl aq. was added and the mixture was incubated on ice for 6 h. The reaction was quenched by adding 80 μL of 300 mM NaOAc [pH 5.2]. Nucleotides were precipitated by the addition of 200 μL ethanol followed by centrifugation. The pellet was rinsed with 60 μL of 0.1 M NaOAc [pH 5.2] in 70% ethanol twice and once with 25 μL of 70% ethanol. This reaction yields 500 pmol of crude aminoacylated tRNA.

In vitro expression of AIP-Ia and its analogs by the Trp-deficient FIT system

A 5 μL *in vitro* translation was prepared by mixing a DNA template, 0.5 mM Trp-deficient 19 amino acids mix, 50 μM of pre-loaded ^{HS}Phe^{4Cl}-tRNA_{CCA}^{Pro1E2}, and in-house PURE system²⁹ and incubated at 37 °C for 30 min.¹¹ The crude reaction mixture was desalted using solid-phase extraction (SPE) C-tip (Nikkyo Technos) and eluted with 80% acetonitrile, 0.5% acetic acid, half saturated with the matrix (*R*)-cyano-4-hydroxycinnamic acid (Bruker), and spotted on a MALDI Ground Steel 384 Target plate. MALDI-TOF-MS measurement was performed under linear or reflector positive mode using an UltraflexXtreme (Bruker) with external calibration (Peptide Calibration Standard II, Bruker).

Thiol capping in peptides by IAA for MS analysis

To 5 μL of *in vitro* translated AIP-Ia analogs, 0.55 μL of 50 mM IAA (#A39271, Thermo Fisher) in ultra-pure water and 0.5 μL of 20 mM TCEP were added and incubated for 1 hour at 25 °C. The reaction mixture was desalted and analyzed by MALDI-TOF MS.

Dethioacetylation

As previously reported,¹¹ to 5 μL of *in vitro* translated AIP-Ia analogs, 0.55 μL of 100 mM cysteine was added and incubated for 40 min at 25 °C. The reaction mixture was desalted and analyzed by MALDI-TOF MS.

LC-MS analysis of AIP-I analogs

To an *in vitro*-expressed crude product was added cold MeOH and the resulting solution was held on ice for 5 min. Precipitates were then spun down at 4 °C and to the supernatant was further added 10-fold volume of 1% TFA. After spinning down, the supernatant was used as a sample for LC-MS. A Waters Xevo G2-XS QToF instrument equipped with an Acquity I-Class UPLC system was used for LC-MS analysis. HPLC was done on an Acquity UPLC Peptide BEH C18 column (dimensions: 150 × 2.1 mm; pore size: 300 Å; particle size: 1.7 μm) using 0.1% (v/v) formic acid in water (solvent A) and 0.1% (v/v) formic acid in acetonitrile (solvent B) as a mobile phase. Analysis was performed at 60 °C and 0.3 mL min⁻¹ flow rate running the following gradient: 1% B for 1.5 min; 1–61% B over 16.5 min; 95% B for 1 min; 1% B for 2 min (total run time: 19.5 min). MS analysis was done in a positive polarity/high-sensitivity mode with a 0.3 s scan time. Capillary voltage was set to 700 V; the electrospray ionization source and desolvation temperatures were 120 °C and 400 °C, respectively. Manufacturer-supplied leucine enkephalin was used as a lockspray standard for continuous mass axis referencing and the recommended lockspray setup procedure was performed prior to every run. LC-MS data were analyzed using MassLynx v.4.1.
