## Exploring the reactivity of homoleptic organozincs towards SO<sub>2</sub>: synthesis and structure of a homologous series of organozinc sulfinates†

Adam Tulewicz, \*<sup>a</sup> Vadim Szejko, <sup>b</sup> Iwona Justyniak, <sup>a</sup>  
Małgorzata Wolska-Pietkiewicz <sup>b</sup> and Janusz Lewiński \*<sup>a,b</sup>

Studies on the reactivity of zinc alkyl compounds towards SO<sub>2</sub> are relatively less explored than either oxygenation or hydrolysis reactions. We report on the environmentally friendly and efficient syntheses of a homologous series of [(RSO<sub>2</sub>)ZnR]<sub>n</sub> complexes from reactions involving homoleptic R<sub>2</sub>Zn (R = Me, tBu, Ph) compounds and SO<sub>2</sub>. Diffusion ordered spectroscopy experiments indicate that the resulting compounds predominately occur as solvated dimers, [(RSO<sub>2</sub>)ZnR(THF)]<sub>2</sub>, in THF solution irrespective of the character of the group bonded to the zinc centres. In turn, these organozinc sulfinates exhibit structurally diversified molecular and supramolecular arrangements in the solid state, as evidenced by single-crystal X-ray diffraction studies. The methyl compound crystallises as a one-dimensional polymer, [(MeSO<sub>2</sub>)ZnMe]<sub>n</sub>, and the use of tBu<sub>2</sub>Zn and Ph<sub>2</sub>Zn leads to molecular aggregates, a tetramer [(tBuSO<sub>2</sub>)ZntBu]<sub>4</sub>, and a solvated [(PhSO<sub>2</sub>)ZnPh]<sub>2</sub>·2THF dimer, respectively. In addition, new theoretical insights have been gained by modelling the direct trapping of homoleptic organozinc compounds with SO<sub>2</sub> using DFT calculations.

## Introduction

Studies on the reactivities of zinc alkyl compounds towards small inorganic molecules lie at the heart of organometallic chemistry. Primary attempts to react homoleptic organozinc compounds with small inorganic reagents can be traced back to the middle of the XIXth century.<sup>1,2</sup> Armoured with experimental creativity, it was Edward Frankland who synthesised 'zincethyl', known nowadays as diethylzinc, and reacted it with molecular dioxygen and water. The legacy of Frankland has continued ever since. Modern experiments performed in our group on the activation of dioxygen on Zn–C reactive species led to the isolation of the first alkylzinc alkylperoxides and provided a new look at the reactivities of zinc alkyls towards dioxygen.<sup>3,4</sup> Strikingly, the first structurally well-defined product derived from the hydrolysis of a dialkylzinc compound was reported only in 2011.<sup>5</sup> Since then, a set of compelling

results regarding the hydrolysis of homo- and heteroleptic zinc alkyls including stable zinc hydroxide and zincoxane molecular clusters<sup>6,7</sup> or even ZnO quantum dots have been reported.<sup>8–11</sup> Furthermore, it was demonstrated that reactions between selected alkylzinc hydroxides and carbon dioxide could efficiently provide novel clusters and nanomaterials based on zinc carbonates with unique physicochemical properties.<sup>12–14</sup> In turn, studies on the reactivities of homoleptic and heteroleptic organozinc compounds towards SO<sub>2</sub> have been explored to a lesser extent, which may seem surprising, for example, in view of the potential use of heteroleptic zinc sulfinates as catalysts for the copolymerisation of CO<sub>2</sub> with epoxides<sup>15–18</sup> or zinc bis(alkanesulfinate)s as general reagents for the formation of radical species in organic synthesis.<sup>19–22</sup> The latter have been usually generated from the corresponding sulfonyl chlorides by treatment with zinc dust, and the requirement of a large excess of Zn metal has restricted their employment under *in situ* conditions.<sup>19</sup> Thus, the development of efficient synthetic procedures for zinc organosulfinates is highly desirable.

To provide sufficient breadth and depth of literature coverage on the direct trapping of organometallic compounds with SO<sub>2</sub>, we note that the research in the field started many decades ago and represents efficient methods for the preparation of a vast array of metal sulfinates,<sup>19,23–28</sup> featuring exceptionally rich coordination chemistry.<sup>29–32</sup> The renewed interest

has been rekindled by reactions of frustrated Lewis pairs or related compounds with  $\text{SO}_2$ .<sup>32–37</sup> Remarkably, to our knowledge, there are only two reports where the crystal structures of the products of  $\text{SO}_2$  insertion into homoleptic organozincs have been investigated. Roesky *et al.*<sup>38</sup> showed that the reaction between  $\text{SO}_2$  and zincocens affords a double insertion product,  $[\text{Zn}(\text{O}_2\text{SCp}^*)_2(\text{tmeda})]$ , as well as  $[\text{Zn}_4(\text{O}_2\text{SCp}^*)_6\text{O}]$  clusters that contain a  $\text{Zn}_4\text{O}$  structural motif. Moreover, thermal decomposition of  $[\text{Zn}(\text{O}_2\text{SCp}^*)_2(\text{tmeda})]$  resulted in the formation of  $[\text{Zn}_2(\mu\text{-SO}_3)(\mu\text{-S}_2\text{O}_4)(\text{tmeda})_2]$ . The latter result carries valuable information on the thermodynamic stability of the  $\text{O}_2\text{SCp}^{*-}$  anion, in particular, regarding the possibility of its transformations into other ions, *i.e.*, sulfuroxo anions. More recently, our group initiated studies on the  $\text{Et}_2\text{Zn}/\text{SO}_2$  system.<sup>39</sup> We showed that various multidimensional networks bearing either  $(\text{EtSO}_2)\text{ZnEt}$  or  $(\text{EtSO}_2)_2\text{Zn}$  motifs could be obtained with respect to (i) the reaction stoichiometry, (ii) the presence of a certain Lewis base and (iii) the type of solvent chosen for performing the reaction.

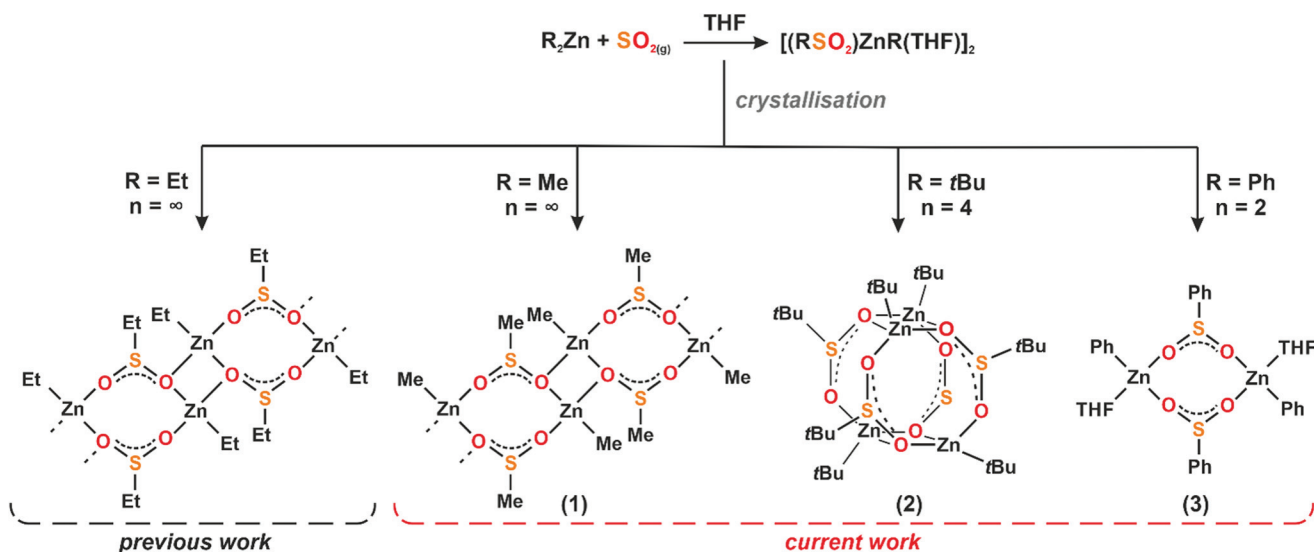

We and others have well documented that the character of Zn-bonded alkyl groups dramatically affects the reactivity of organozincs towards small molecules and the composition and structure of the resulting products.<sup>40–46</sup> Driven by both curiosity to explore new aspects of reactivities of organozinc systems towards  $\text{SO}_2$  and the search for new (L)ZnR-type precursors or building blocks of functional materials, herein we turn our attention to the studies of equimolar reactions between selected homoleptic organozinc compounds with  $\text{SO}_2$ . In particular, we report on reactions between  $\text{R}_2\text{Zn}$  (R = Me, *t*Bu, Ph) and  $\text{SO}_2$  in THF, which allowed for the synthesis of a homologous series of organozinc sulfinates in the form of solvated  $[(\text{RSO}_2)\text{ZnR}(\text{THF})]_2$  dimers in a THF solution, and the isolation of structurally diversified molecular and supramolecular arrangements in the solid state, *i.e.*, a one-dimensional coordination polymer  $[(\text{MeSO}_2)\text{ZnMe}]_n$  (1), a tetrameric cluster

$[(t\text{BuSO}_2)\text{Zn}t\text{Bu}]_4$  (2) to a solvated dimer of the formula  $[(\text{PhSO}_2)\text{ZnPh}]_2 \cdot 2\text{THF}$  (3), respectively (Scheme 1).

## Results and discussion

### Synthesis and spectroscopic characterisation

Immediate reactions between  $\text{R}_2\text{Zn}$  (R = Me, *t*Bu, Ph) and gaseous  $\text{SO}_2$  in the molar ratio 1 : 1 were carried out according to Scheme 1. Colourless cubic crystals of either 1, 2 or 3 were isolated in high yield after standard workup (for details, see the Experimental section). Compounds 1–3 were fully characterised using elemental analysis, spectroscopic and single-crystal X-ray diffraction techniques. The FTIR spectra of compounds 1–3 comprise intense to medium bands in the range  $876\text{--}1043\text{ cm}^{-1}$ , assigned to the sulfur–oxygen vibrations,<sup>35</sup> which confirms the presence of the sulfinato anion. The  $^1\text{H}$  NMR spectrum of 1 shows two well-resolved singlets at 2.38 ppm and  $-0.91$  ppm, derived from the protons of  $\text{MeSO}_2$  and  $\text{MeZn}$  groups, respectively (see the ESI, Fig. S1†), while the  $^{13}\text{C}$  NMR spectrum of 1 shows two signals at 49.33 ppm and  $-16.9$  ppm from the carbon atoms of the methylsulfinato anion and the Zn–Me group, respectively (see the ESI, Fig. S2†). Similarly, inspection of the  $^1\text{H}$  NMR spectrum of 2 reveals two separated sharp singlets at 1.07 ppm and 1.01 ppm with equal intensities, assigned to the methyl protons of *t*BuSO<sub>2</sub> and *t*BuZn groups, respectively (see the ESI, Fig. S4†). The  $^{13}\text{C}$  NMR spectrum of 2 shows two intensive sharp singlets of the primary carbons of the *t*BuSO<sub>2</sub> and *t*BuZn groups at 32.89 ppm and 20.77 ppm, respectively. Less intensive signals from the quaternary carbons were found at 55.42 ppm and 19.72 ppm, respectively (see the ESI, Fig. S5†). The  $^1\text{H}$  NMR spectrum of 3 comprises an overlapping multiplet from phenyl protons that fall within a range between 6.98 ppm and 7.79 ppm. In addition, the characteristic multiplets of THF protons were

Scheme 1 Reactivity of  $\text{Me}_2\text{Zn}$ ,  $t\text{Bu}_2\text{Zn}$  and  $\text{Ph}_2\text{Zn}$  towards  $\text{SO}_2$  leading to  $(\text{MeSO}_2)\text{ZnMe}$  (1),  $(t\text{BuSO}_2)\text{Zn}t\text{Bu}$  (2) and  $(\text{PhSO}_2)\text{ZnPh}$  (3).

recorded at 1.77 ppm and 3.62 ppm, with the intensities indicative of the partial desolvation of compound **3** (see the ESI, Fig. S7†). The  $^{13}\text{C}$  NMR spectrum of **3** features signals from the phenyl groups at 153.11 and 152.38 ppm, and in the range of 139.59–125.62 ppm. Signals assigned to the secondary and primary carbons of THF were found at 26.37 ppm and 68.25 ppm, respectively. Moreover, the DOSY experiments indicate that compounds **1–3** occur as solvated dimers  $[(\text{RSO}_2)\text{ZnR}(\text{THF-}d_8)]_2$  in THF- $d_8$  solution irrespective of the character of the alkyl group bonded to zinc centres (for details, see the ESI†).

Furthermore, some combinations of heteroleptic  $(\text{L})\text{ZnR}$ -type complexes with homoleptic  $\text{R}_2\text{Zn}$  compounds act as arguably the most important organozinc catalytic systems in organic synthesis<sup>47,48</sup> or precursors of various functional materials.<sup>14,49</sup> Nevertheless, the chemistry of  $(\text{L})\text{ZnR}/\text{R}_2\text{Zn}$  systems remains both relatively poorly understood and a subject of constant debate.<sup>50,51</sup> Thus, we performed controlled experiments on the reactivity of selected  $[(\text{RSO}_2)\text{ZnR}]/\text{R}'_2\text{Zn}$  systems. In this regard, we prepared THF solutions of **1** and **2** that were subsequently treated with equimolar amounts of  $t\text{Bu}_2\text{Zn}$  and  $\text{Me}_2\text{Zn}$ , respectively (Scheme 2). Strikingly, we found that in the first case,  $(\text{MeSO}_2)\text{ZnMe}/t\text{Bu}_2\text{Zn}$ , the zinc-bonded methyl group was easily substituted by the *tert*-butyl group (see the ESI, Fig. S10 and 11†). Conversely, in the case of the  $(t\text{BuSO}_2)\text{Zn}t\text{Bu}/\text{Me}_2\text{Zn}$  system no exchange was observed as indicated by the NMR studies (see the ESI, Fig. S12 and 13†). The reasons for such different reactivities are unclear and must be further investigated.

### Solid-state structures

Remarkably, the nature of the zinc-bonded alkyl substituents has a profound effect on the solid-state structure of the title organozinc sulfonates. Compound **1** crystallises in triclinic space group  $P\bar{1}$  as a 1D coordination polymer constructed of dinuclear  $[(\text{MeSO}_2)\text{ZnMe}]_2$  units incorporating sulfonato-O, O'-type ligands (Fig. 1) and interconnected through the  $[\text{Zn}_2(\mu_2\text{-O}_2)]$  rings to form an extended chain along the  $a$  axis. The structural constitution of **1** reflects the polymeric structure of the previously reported ethylzinc ethylsulfinate derivative,<sup>38</sup>  $[(\text{EtSO}_2)\text{ZnEt}]_n$ . The Zn–O bond distances within the molecular  $[(\text{MeSO}_2)\text{ZnMe}]_2$  unit fall in the range of 1.988–2.096 Å, and the Zn–O bonds connecting these units are of a similar length of 2.075 Å. The S–C bond length is 1.772 Å, and the S–O bonds of length 1.517–1.551 Å, along with O–S–O angles (106.9°), are

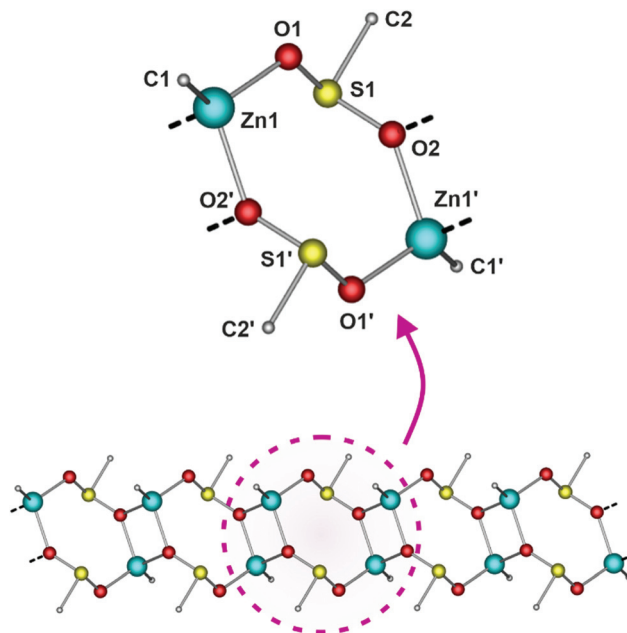

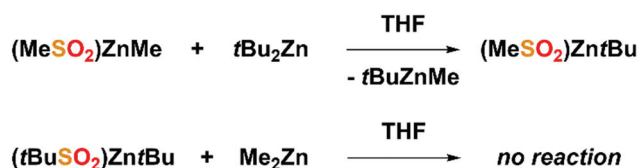

Fig. 1 Molecular structure and single polymeric chain (view along the crystallographic  $a$  axis) of **1**. Hydrogen atoms have been omitted for clarity.

similar to values observed for other metal sulfinate complexes.<sup>30,38,39</sup>

Compound **2** crystallises in the  $P\bar{1}$  triclinic space group. An inspection of the structure of **2** revealed that metal centres adopt a tetrahedral geometry, and four  $t\text{BuZn}$  moieties are stabilised by four *tert*-butylsulfinate anions (Fig. 2a). As a result, the molecular structure of **2** comprises two sulfonato-O, O'-type  $[(t\text{BuSO}_2)\text{Zn}t\text{Bu}]_2$  heterocycles joined within two  $[\text{Zn}_2(\mu_2\text{-O}_2)]$  moieties forming tetranuclear cluster  $[(t\text{BuSO}_2)\text{Zn}t\text{Bu}]_4$ . Interestingly, the core of compound **2** is isostructural to quasi-cube-shaped *tert*-butylzinc diorganophosphate  $[t\text{BuZn}(\text{O}_2\text{P}(\text{OR})_2)]$  ( $\text{R} = \text{Me}, \text{Ph}$ ) complexes previously reported by us.<sup>52</sup> The Zn–O bond lengths in **2** were found to be in the range between 2.005 and 2.121 Å and the S–O distances between 1.510 and 1.555 Å, similar to the bond values found in the case of compound **1** and related alkylzinc sulfonates.<sup>39</sup> Compound **3** crystallises in triclinic space group  $P\bar{1}$ . An introduction of the aromatic group provided dinuclear solvate  $[(\text{PhSO}_2)\text{ZnPh}(\text{THF})]_2$  (Fig. 2b). Two metal centres of **3** are connected by the  $\text{PhSO}_2\text{-}\mu_2$ -bridging moieties forming an octanuclear macrocycle that adopts a chair conformation similar to that observed for compound **1**, with the phenyl groups located *trans* to each other across the ring. However, contrary to **1** and **2**, the tetrahedral coordination sphere located on each metal centre of **3** is completed by a single THF molecule. That results in a monomeric structural motif, preferable over either the 1D coordination polymer or tetranuclear cluster, likely due to the steric hindering introduced by phenyl rings. The Zn–O<sub>sulfinate</sub> distances of **3** are observed to be in the range of 1.987–2.088 Å, and the Zn–O<sub>THF</sub> bonds to outer solvent molecules are longer

Scheme 2 Controlled experiments on the reactivities of  $[(\text{RSO}_2)\text{ZnR}]$  species towards homoleptic organozincs.

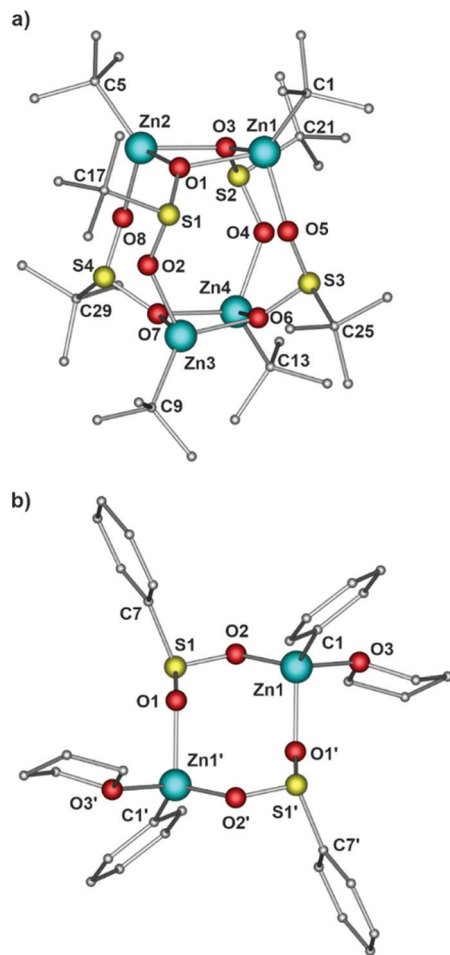

Fig. 2 Molecular structure of 2 (a) and 3 (b). Hydrogen atoms have been omitted for clarity.

and are of length 2.088 Å. The S–O bonds are similar within the molecule and their lengths are between 1.527 and 1.528 Å. The O–S–O conical angles (107.37°) together with the aforementioned parameters are similar to that observed for other zinc sulfinate compounds.<sup>30,38,39</sup>

## DFT studies

DFT calculations were subsequently performed to explore the thermodynamic landscape associated with insertions of SO<sub>2</sub> into the studied systems as well as to deeply investigate the studies on the reactivity of SO<sub>2</sub> towards various alkylzincs (Fig. 3). In all the considered cases, the reaction between R<sub>2</sub>Zn and SO<sub>2</sub> starts with the formation of van der Waals complexes, where the oxygen atom from SO<sub>2</sub> is attracted by the metal centre, similarly to our previous studies with Et<sub>2</sub>Zn/SO<sub>2</sub> systems. In the next step, the formation of the transition state occurs. In the case of Ph<sub>2</sub>Zn/SO<sub>2</sub>, the geometry of the transition state remains only slightly distorted, in contrast to the geometries of transition states found within the Me<sub>2</sub>Zn/SO<sub>2</sub> and *t*Bu<sub>2</sub>Zn/SO<sub>2</sub> systems. This may explain to some extent the relatively low barrier of reaction found for the insertion of SO<sub>2</sub> into Ph<sub>2</sub>Zn. Note that the elongation of the Zn–C bond, associated with the R<sub>2</sub>Zn/SO<sub>2</sub> transition state, is energetically highly unfavoured, in particular for the small alkyls. This effect may explain the higher value of the energy barrier of +14.9 kcal mol<sup>-1</sup>, found for the insertion of SO<sub>2</sub> into Me<sub>2</sub>Zn. Finally, the overall energetic effect of the R<sub>2</sub>Zn/SO<sub>2</sub> reactions remains highly negative and similar to the results obtained within related studies,<sup>24,25</sup> and suggests that reactions between R<sub>2</sub>Zn and SO<sub>2</sub> should be driven in a one way direction.

## Experimental section

### General remarks

All reactions and post-synthetic manipulations were conducted under an argon or nitrogen atmosphere using standard Schlenk and glovebox techniques (MBraun UniLab Plus; <0.1 ppm O<sub>2</sub>, <0.1 ppm H<sub>2</sub>O). All solvents were purified by passage through activated aluminium oxide (MBraun SPS) and stored over 3 Å molecular sieves. Prior to use, deuterated solvents were dried over Na/K, distilled under an argon atmosphere before use, and stored over molecular sieves. Di-*tert*-butylzinc was prepared according to the literature procedure.<sup>53</sup> All reagents used in this study were of commercial grade and

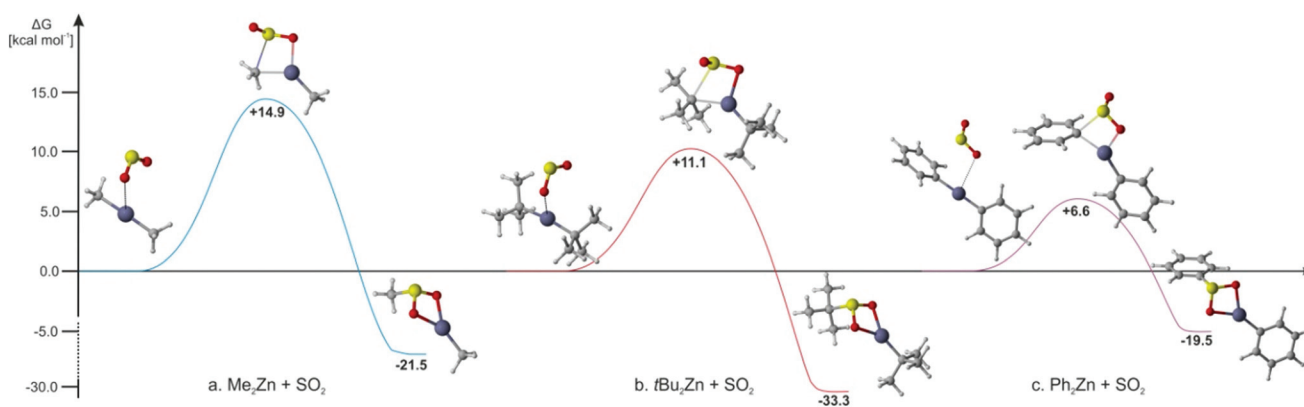

Fig. 3 The comparison of reaction pathways of SO<sub>2</sub> insertion into Me<sub>2</sub>Zn (a; blue line), *t*Bu<sub>2</sub>Zn (b; red line) and Ph<sub>2</sub>Zn (c; violet line). The values of ΔG have been referenced to the Gibbs free energies of the van der Waals complexes.

obtained from Sigma-Aldrich Co or abcr GmbH. Stoichiometric amounts of SO<sub>2</sub> (determined by using the Clausius–Clapeyron equation) were added to the reaction mixtures through a syringe. NMR spectra were acquired with a Varian Mercury 400 MHz spectrometer at 298 K unless otherwise specified and were referenced to the residual <sup>1</sup>H or <sup>13</sup>C signals of the deuterated solvents. FTIR spectra were recorded with a Bruker Vertex 80V spectrometer equipped with a diamond ATR (attenuated total reflection) unit. Elemental analysis was performed by using a UNICUBE (Elementar Analysensysteme GmbH).

**Synthesis of [(MeSO<sub>2</sub>)ZnMe]<sub>n</sub> (1).** To Me<sub>2</sub>Zn (0.35 mL of *ca.* 2 M solution in hexane, 0.7 mmol) was added THF (5 mL) and then 1 equiv. of SO<sub>2</sub> (*ca.* 17.1 cm<sup>3</sup>, 298 K, 1 atm) was condensed onto the stirring solution at room temperature. The reaction mixture was then stirred for an additional 1 h. The solution was then dried under vacuum and the solid residue, obtained after the removal of the solvent, was afterwards dissolved in THF (1 mL). Compound **1** was obtained as colourless, long needle-shaped crystals after crystallisation at RT. Isolated yield: 98 mg, 88%; <sup>1</sup>H NMR (400 MHz, THF-*d*<sub>8</sub>, 298 K) δ = 2.38 (s, 3H; CH<sub>3</sub>SO<sub>2</sub>), −0.91 (s, 3H; CH<sub>3</sub>Zn) ppm. <sup>13</sup>C NMR (101 MHz, THF-*d*<sub>8</sub>, 298 K) δ = 49.33 ppm. IR (ATR): 2951 (vw), 2906 (vw), 2843 (vw), 1415 (vw), 1397 (vw), 1302 (vw), 1155 (vw), 1004 (s), 958 (s), 945 (s), 895 (vs), 703 (w), 674 (m), 538 (s), 450 (w) cm<sup>−1</sup>. Elemental analysis calcd (%) for C<sub>4</sub>H<sub>12</sub>O<sub>4</sub>S<sub>2</sub>Zn<sub>2</sub> (319.02): C 15.06, H 3.79, S 20.10; found (%): C 14.96, H 3.63, S 18.54.

**Synthesis of [(*t*BuSO<sub>2</sub>)Zn*t*Bu]<sub>4</sub> (2).** The procedure was similar to that described for **1**, but was carried out by using *ca.* 0.8 M solution of *t*Bu<sub>2</sub>Zn in toluene. Compound **2** was obtained as colourless, long needle-shaped crystals after crystallisation at RT. Isolated yield: 158 mg, 93%; <sup>1</sup>H NMR (400 MHz, THF-*d*<sub>8</sub>, 298 K) δ = 1.07 (s, 9H; (CH<sub>3</sub>)<sub>3</sub>CSO<sub>2</sub>), 1.01 (s, 9H; (CH<sub>3</sub>)<sub>3</sub>CZn) ppm. <sup>13</sup>C NMR (101 MHz, THF-*d*<sub>8</sub>, 298 K) δ = 55.42, 32.89, 20.77, 19.72 ppm. IR (ATR): 2978 (vw), 2940 (vw), 2918 (vw), 2862 (vw), 2808 (w), 2755 (vw), 2695 (vw), 1473, (vw), 1461 (w), 1388 (vw), 1360 (w), 1187 (vw), 1043 (s), 1007 (m), 967 (m), 889 (vs), 815 (w), 790 (w), 689 (vw), 613 (s), 552 (w), 516 (vw), 463 (vw), 437 (w) cm<sup>−1</sup>. Elemental analysis calcd (%) for C<sub>32</sub>H<sub>72</sub>O<sub>8</sub>S<sub>4</sub>Zn<sub>4</sub> (974.68): C 39.43, H 7.45, S 13.16; found (%): C 39.67, H 7.12, S 12.82.

**Synthesis of [(PhSO<sub>2</sub>)ZnPh]<sub>2</sub> (3).** The procedure was similar to that described for **1**, but was carried out by using 0.153 g (0.7 mmol) of Ph<sub>2</sub>Zn. Compound **3** was obtained as colourless, long needle-shaped crystals after crystallisation from a THF solution at −20 °C. Isolated yield: 150 mg, 76%; <sup>1</sup>H NMR (400 MHz, THF-*d*<sub>8</sub>, 298 K) δ = 7.79–7.73 (m, 2H, C-*H*<sub>Ar</sub>), 7.46–7.37 (m, 5H, C-*H*<sub>Ar</sub>), 7.06–6.98 (m, 3H, C-*H*<sub>Ar</sub>), 3.65–3.59 (m, 2H, −OCH<sub>2</sub><sup>THF</sup>−), 1.80–1.74 (m, 2H, −CH<sub>2</sub><sup>THF</sup>−) ppm. <sup>13</sup>C NMR (101 MHz, THF-*d*<sub>8</sub>, 298 K) δ = 153.11, 152.38, 139.59, 131.30, 129.41, 127.22, 126.32, 125.62, 68.25, 26.37 ppm. IR (ATR): 3060 (vw), 3030 (vw), 2981 (vw), 2889 (vw), 1583 (vw), 1475 (w), 1442 (w), 1419 (w), 1249 (vw), 1177 (vw), 1088 (w), 1003 (s), 990 (s), 954 (vs), 876 (m), 754 (s), 722 (w), 702 (s), 685 (s), 584 (m), 502 (w), 473 (m), 443 (m) cm<sup>−1</sup>. Elemental analysis

calcd (%) for C<sub>32</sub>H<sub>36</sub>O<sub>6</sub>S<sub>2</sub>Zn<sub>2</sub> (711.51): C 54.02, H 5.10, S 9.01; found (%): C 53.69, H 4.64, S 8.46.

**Reaction of **1** with *t*Bu<sub>2</sub>Zn.** To the THF solution of [(MeSO<sub>2</sub>)ZnMe] (0.8 mmol) obtained in the aforementioned procedure was added *t*Bu<sub>2</sub>Zn (1 ml of *ca.* 0.8 M solution in toluene, 0.8 mmol). The reaction mixture was then stirred for 1 h. After the standard workup the solid residue was subjected to NMR studies.

**Reaction of **2** with Me<sub>2</sub>Zn.** The procedure was similar to that described for the reaction between **1** and *t*Bu<sub>2</sub>Zn carried out by using (0.7 mmol) [(*t*BuSO<sub>2</sub>)Zn*t*Bu] and Me<sub>2</sub>Zn (0.35 mL of *ca.* 2 M solution in hexane, 0.7 mmol).

### X-Ray structure determination

The X-ray data for complexes **1**, **2**, and **3** were collected at 100 (2) K on a SuperNova Agilent diffractometer using graphite monochromated MoKα radiation (λ = 0.71073 Å). The data were processed with CrysAlisPro.<sup>54</sup> The structure was solved by direct methods using the SHELXS-97 program and was refined by full matrix least-squares on *F*<sup>2</sup> using the program SHELXL.<sup>55</sup> All non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were added to the structure model at geometrically idealised coordinates and refined as riding atoms.

**Crystal data for **1** (CCDC-2116783†).** [C<sub>2</sub>H<sub>6</sub>O<sub>2</sub>SZn]<sub>n</sub>: *M* = 159.50, triclinic, space group *P* $\bar{1}$  (no. 2), *a* = 4.5135(8) Å, *b* = 7.7984(11) Å, *c* = 7.8400(13) Å, α = 89.141(12)°, β = 80.887(14)°, γ = 84.090(13)°, *U* = 271.02(8) Å<sup>3</sup>, *Z* = 2, *F*(000) = 160, *D*<sub>c</sub> = 1.954 g cm<sup>−3</sup>, μ(Mo-Kα) = 4.785 mm<sup>−1</sup>, θ<sub>max</sub> = 26.500°, 1117 unique reflections. Refinement converged at *R*<sub>1</sub> = 0.0701, *wR*<sub>2</sub> = 0.1688 for all data (*R*<sub>1</sub> = 0.0632, *wR*<sub>2</sub> = 0.1609 for 977 reflections with *I*<sub>o</sub> > 2σ(*I*<sub>o</sub>)). The goodness-of-fit on *F*<sup>2</sup> was equal to 1.088.

**Crystal data for **2** (CCDC-2116784†).** C<sub>32</sub>H<sub>72</sub>O<sub>8</sub>S<sub>4</sub>Zn<sub>4</sub>: *M* = 974.61, triclinic, space group *P* $\bar{1}$  (no. 2), *a* = 11.9492(3) Å, *b* = 12.8183(7) Å, *c* = 16.1223(5) Å, α = 86.157(3)°, β = 78.812(2)°, γ = 75.515(3)°, *U* = 2345.05(16) Å<sup>3</sup>, *Z* = 2, *F*(000) = 1024, *D*<sub>c</sub> = 1.380 g cm<sup>−3</sup>, μ(Mo-Kα) = 2.238 mm<sup>−1</sup>, θ<sub>max</sub> = 26.997°, 10 221 unique reflections. Refinement converged at *R*<sub>1</sub> = 0.0611, *wR*<sub>2</sub> = 0.0720 for all data (*R*<sub>1</sub> = 0.0374, *wR*<sub>2</sub> = 0.0646 for 7731 reflections with *I*<sub>o</sub> > 2σ(*I*<sub>o</sub>)). The goodness-of-fit on *F*<sup>2</sup> was equal to 1.019.

**Crystal data for **3** (CCDC-2116785†).** C<sub>32</sub>H<sub>36</sub>O<sub>6</sub>S<sub>2</sub>Zn<sub>2</sub>: *M* = 711.47, triclinic, space group *P* $\bar{1}$  (no. 2), *a* = 8.792(5) Å, *b* = 9.326(5) Å, *c* = 10.669(5) Å, α = 78.722(5)°, β = 74.655(5)°, γ = 67.772(5)°, *U* = 776.4(7) Å<sup>3</sup>, *Z* = 1, *F*(000) = 368, *D*<sub>c</sub> = 1.522 g cm<sup>−3</sup>, μ(Mo-Kα) = 1.722 mm<sup>−1</sup>, θ<sub>max</sub> = 30.163°, 3931 unique reflections. Refinement converged at *R*<sub>1</sub> = 0.0449, *wR*<sub>2</sub> = 0.0872 for all data (*R*<sub>1</sub> = 0.0361, *wR*<sub>2</sub> = 0.0826 for 3412 reflections with *I*<sub>o</sub> > 2σ(*I*<sub>o</sub>)). The goodness-of-fit on *F*<sup>2</sup> was equal to 1.050.

### Theoretical details

The geometries of the molecules chosen as model systems were optimised by using density functional theory (DFT) with the B3LYP<sup>56,57</sup> functional in the 6-31++G(2d,2p) basis set with the D3(BJ) correction<sup>58,59</sup> added in order to improve the

description of dispersion forces. Frequency analysis was performed in order to confirm the nature of minima and maxima. Intrinsic reaction coordinate calculations (IRC)<sup>60</sup> were additionally done to check the quality of the transition states. All the calculations were done with the Gaussian suite of codes.<sup>61</sup> Figures have been prepared with the CYLview visualisation software.<sup>62</sup>

## Conclusions

Finding new potential (L)ZnR-type reagents for organic synthesis or precursors of nanomaterials that can be efficiently synthesised from some air pollutants may represent an important step toward a better future. Simultaneously, explorations of reactivity of homoleptic dialkylzincs towards sulfur dioxide still leave many opportunities for scientific discoveries. In this vein, we performed the first systematic studies on the effect of the nature of Zn-bonded alkyl groups on both the SO<sub>2</sub> insertion process and structure of the resulting products in the solid state and solution. The direct trapping of homoleptic R<sub>2</sub>Zn compounds with SO<sub>2</sub> allowed for the isolation and characterisation of a homologous series of organozinc sulfinate [(RSO<sub>2</sub>)ZnR] species that are hardly accessible with alternative methods. Moreover, we showed that the resulting organozinc sulfinate occur as solvated dimers [(RSO<sub>2</sub>)ZnR(THF)]<sub>2</sub> in THF solution irrespective of the character of the substituent. In turn, the identity of the Zn-R group determines whether the [(RSO<sub>2</sub>)ZnR]<sub>n</sub> product acquires a dimeric, tetrameric or 1D-polymeric constitution in the solid state. Interestingly, the DFT calculations performed on the set of equimolar R<sub>2</sub>Zn/SO<sub>2</sub> systems confirm that the SO<sub>2</sub> insertion into the Zn–C bond can be characterised by a moderate value of the energy barriers and the highly exothermic character of the SO<sub>2</sub> insertion.

Finally, the reported investigations fill a missing gap in the realm of (L)ZnR complexes as new precursors of functional materials and further studies on the application of organozinc sulfinate as efficient precursors of surface-modified ZnO nanostructures are in progress.

## Conflicts of interest

There are no conflicts to declare.

## Acknowledgements

The authors gratefully acknowledge the National Science Centre, Poland (grant OPUS 2017/25/B/ST5/02484 and grant MINIATURA 2021/05/X/ST4/00520) for financial support. Moreover, the ICM University of Warsaw Computer Center is acknowledged for facilities and computer time allocation within the grant G70-21. The authors would also like to thank Dr Piotr Bernatowicz for assistance with DOSY experiments.
