Importance of physical units in the Boltzmann plot method

Tobias Völker * and Igor B. Gornushkin

The Boltzmann plot is one of the most widely used methods for determining the temperature in different types of laboratory plasmas. It operates on the logarithm as a function of the dimensional argument, which assumes that the correct physical units are used. In many works using the Boltzmann method, there is no analysis of the dimension of this argument, which may be the cause of a potential error. This technical note offers a brief description of the method and shows how to correctly use physical units when using transcendental functions like the logarithm.

1 Introduction

One of the most popular methods for determining the temperature in laboratory plasmas is the Boltzmann plot method. It is based on the solution of the radiative transfer equation for a uniform, isothermal and optically thin plasma along the line of sight. To construct the Boltzmann plot, the equation is linearized by taking the logarithm from both parts of the equation. The logarithm is a dimensionless transcendental function whose argument must also be dimensionless. Unfortunately, in many publications there is no analysis of the dimension of the sublogarithmic expression, and the value of the function is expressed in the wrong units. This technical note aims to address this issue by following the general discussion of dimensional analysis of arguments to transcendental functions.¹ Specific goals are: (i) to reduce the argument of the logarithm in the expression for the Boltzmann plot to a dimensionless form and (ii) to recommend the correct units for the abscissa and ordinate of the Boltzmann plot.

2 Boltzmann plot and dimensional analysis

Under the condition of a homogeneous, stationary, and isothermal plasma in local thermodynamic equilibrium, the intensity of an optically thin emission line is given by²

$$I_{ki}^{\lambda} = \frac{hc}{\lambda_{ki}} \frac{g_k A_{ki}}{U_s^z(T)} n_s^z l \exp\left(-\frac{E_k}{k_b T}\right) \quad (1)$$

where I (W m^{-2}) is the spectral radiance integrated over the line profile and full solid angle, h (J s) is the Planck constant, c (m s^{-1}) is the speed of light in free space, λ_{ki} (m) is the transition wavelength, g_k (dimensionless) is the degeneracy of the upper

transition state, A_{ki} (s^{-1}) is the Einstein coefficient for spontaneous emission, $U_s^z(T)$ (dimensionless) is the partition function, n_s^z (m^{-3}) is the number density, l (m) is the path length, E_k (J) is the energy of the upper transition state, k_b (J K^{-1}) is the Boltzmann constant, and T (K) is the temperature. Index s enumerates the plasma species and z the charge state.

To construct the Boltzmann plot, eqn (1) is rearranged and linearized with respect to E_k using the logarithmic function

$$\ln\left(\frac{I_{ki}^{\lambda} \lambda_{ki}}{g_k A_{ki}}\right) = \ln\left(\frac{hc n_s^z l}{U_s^z(T)}\right) - \frac{E_k}{k_b T} \quad (2)$$

Inserting the units into eqn (2) gives

$$\ln\left(\frac{[\text{W m}^{-2}][\text{m}]}{[1][\text{s}^{-1}]}\right) = \ln\left(\frac{[\text{J s}][\text{m s}^{-1}][\text{m}^{-3}][\text{m}]}{[1]}\right) - \frac{[\text{J}]}{[\text{J K}^{-1}][\text{K}]} \quad (3)$$

The analysis and reduction of units to basic ones in eqn (3) shows that while the second term in the right-hand side is dimensionless, the expressions under the logarithms are dimensioned (kg m s^{-2}) that is unacceptable for a transcendental function like the logarithm. To correct this and rewrite eqn (2) in the dimensionless form, both sides of eqn (1) should be normalized to the unit radiance $I_0 = \frac{h_0 c_0}{\lambda_0} A_0 n_0 l_0 = 1 \text{ W m}^{-2}$ to yield

$$\frac{I_{ki}^{\lambda}}{I_0} = \frac{\frac{hc}{\lambda_{ki}} \frac{g_k A_{ki}}{U_s^z(T)} n_s^z l \exp\left(-\frac{E_k}{k_b T}\right)}{\frac{h_0 c_0}{\lambda_0} A_0 n_0 l_0} \quad (4)$$

The numeric values of h_0 , c_0 , λ_0 , A_0 , n_0 , and l_0 can be taken equal to unity and expressed in the same system of units (e.g., SI) as that in the original expression eqn (1). Rearranging eqn (4) into the form of eqn (2), one obtains the usual Boltzmann plot

Bundesanstalt für Materialforschung und -prüfung (BAM), Richard-Willstätter-Straße 11, Berlin 12489, Germany. E-mail: tobias.voelker@bam.de

equation, but with dimensionless arguments under the logarithm

$$\ln\left(\frac{I_{ki}^{\lambda} \lambda_{ki}}{g_k A_{ki}} \frac{A_0}{I_0 \lambda_0}\right) = \ln\left(\frac{hcn_s^2 l}{U_s^z(T)} \frac{1}{h_0 c_0 n_0 l_0}\right) - \frac{E_k}{k_b T} \quad (5)$$

Obviously, the normalization to the unit radiance does not change the original value of the radiance in eqn (1); it only converts it into the dimensionless form. Furthermore, eqn (5)

implies that the abscissa of the plot $\ln\left(\frac{I_{ki}^{\lambda} \lambda_{ki}}{g_k A_{ki}} \frac{A_0}{I_0 \lambda_0}\right)$ versus E_k has the unit of energy and the ordinate is unitless. For convenience and compactness, eqn (5) can be written as eqn (2), but with the understanding that the argument of the logarithmic function is normalized to the chosen system of units.

Most importantly, in practice, the response function must be calibrated in physical units (W m^{-2}) to be able to use the Boltzmann plot equation. However, this limitation can be removed if the Boltzmann plot is built for a narrow spectral range (flat response function), and all spectral lines are normalized to some standard line from this range. In this case, the Boltzmann plot equation becomes dimensionless expressed by

$$\ln\left(\frac{I_{ki}^{\lambda} \lambda_{ki}}{I_{ki}^{\lambda_r} \lambda_{ki}} \frac{A_{ki}^r g_k^r}{A_{ki} g_k}\right) = \ln\left(\frac{n_s^z / U_s^z(T)}{n_s^{z,r} / U_s^{z,r}(T)}\right) - \frac{E_k + E_k^r}{k_b T} \quad (6)$$

Here, the reference line is marked with index r and the constants h , c and path length l are truncated.

A commonly used variant of the Boltzmann plot is the Saha-Boltzmann plot, which provides a more accurate temperature determination because it covers a wider range of upper transition energies. This is achieved by combining atomic and ionic species in a single plot by expressing the corresponding number densities through the Saha equation²

$$\frac{n_s^{z+1} n_e}{n_s^z} = \frac{2(2\pi m_e k_b T)^{3/2}}{h^3} \frac{U_s^{z+1}(T)}{U_s^z(T)} \exp\left(-\frac{\chi_s - \Delta\chi}{k_b T}\right) \quad (7)$$

where m_e (kg) is the electron mass, χ_s (J) and $\Delta\chi$ (J) are the ionization energy and its defect due to the Debye shielding. Following the procedure described above, the analog of eqn (5) for an ionic line reads as follows

$$\ln\left(\frac{I_{jh}^{\lambda} \lambda_{jh}}{g_j A_{jh}} \frac{A_0}{I_0 \lambda_0}\right) - \ln\left(\frac{2(2\pi m_e k_b T)^{3/2}}{n_e h^3}\right) = \ln\left(\frac{hcn_s^2 l}{U_s^z(T)} \frac{1}{h_0 c_0 n_0 l_0}\right) - \frac{\chi_s + E_j - \Delta\chi}{k_b T} \quad (8)$$

Note that the expression under the logarithm in the second term on the left-hand side is dimensionless.

3 Error analysis due to inconsistent physical units

To investigate possible errors that can occur when using inconsistent units in the construction of a Boltzmann plot,

Table 1 Lines used for the Boltzmann plot^a

Ion	λ_{ki} (10^{-9} m)	A_{ki} (10^8 s $^{-1}$)	E_k (10^{-19} J)	g_k
Ti ^{II}	334.94	1.68	6.01	12
Ti ^{II}	390.05	0.28	6.91	10

^a Data are from Ref. 4.

several possible situations are analyzed. All tested scenarios assume a two-point Boltzmann plot using the lines in Table 1. The integrated line intensity is calculated from eqn (1) using the polynomial approximation³ for partition functions. The temperature is assumed to be 10 000 K, the number density of atoms is $1 \times 10^{22} \text{ m}^{-3}$, and the path length is 0.001 m. The points on the Boltzmann plot are calculated from eqn (5).

The first scenario assumes that the emission signal is measured in units of counts, *i.e.*, the spectrometer and detector are not calibrated with a standard light source. If the spectral response function is not flat, then the ratio of the measured intensities at 334.94 nm and 390.05 nm will differ from that emitted by the plasma and, therefore, the temperature determined from the slope of the Boltzmann plot will be incorrect. To analyze a possible error for this case, the spectral response function integrated over the line profile and full solid angle is assumed to be $1 \text{ W (m}^2 \text{ counts)}^{-1}$ in the spectral region around 334 nm and $0.8 \text{ W (m}^2 \text{ counts)}^{-1}$ in the region around 390 nm. By dividing the intensities calculated from eqn (1) by these response function values, the intensities measured by the uncalibrated instrument in units of counts are obtained. After substituting these values into eqn (5) and determining the slope of the Boltzmann plot, a temperature of 7444 K is obtained, which makes a 26% relative error with respect to the original temperature of 10 000 K.

In the second scenario, it is assumed that the spectrometer is calibrated, and the emission signal is measured in the physical units of W m^{-2} but the Boltzmann plot equation is calculated using the non-SI system unit of nm for central wavelengths of emission transitions. In this case, the temperature will be determined correctly because the ordinates of all points on the Boltzmann plane will be shifted vertically to equal distances. However, it should be emphasized that the use of inconsistent units in this case is physically incorrect, leading to the appearance of a unit conversion factor under the sign of the logarithm, which, without changing the slope of the function, will shift its intersection point with the y-axis; such the shift may be undesirable in some applications.

Common to all scenarios is that the use of inconsistent units in the Boltzmann plot equation is incorrect from both mathematical and physical points of view and can lead to erroneous temperature values when using the Boltzmann plot method.

4 Conclusion

Since many papers using the Boltzmann method to measure plasma temperature do not check the dimension of the sub-logarithmic expression, this technical note emphasizes that

such a check is necessary to obtain the correct temperature value. In this context, attention was drawn to the following:

(i) Transcendental functions such as the logarithm require a dimensionless quantity as an argument. This can be achieved by normalizing the equation for the integral line intensity by the unit intensity in the chosen system of units that makes the argument of the logarithm dimensionless. This requires calibration of the spectrometer and detector so that the emission signal can be measured in physical units.

(ii) The abscissa on a Boltzmann plot graph has units of energy, and since the logarithmic function gives a dimensionless unit as the value of the function, the ordinate of the Boltzmann plot graph is therefore dimensionless.

It is also shown that the use of inconsistent units of variables and constants in the argument of the logarithmic function can lead to erroneous temperature values when using the Boltzmann plot method. Several scenarios are considered, including the use of uncalibrated measurements or inconsistent units in a sublogarithmic expression. Therefore, it is recommended to carefully analyze the dimension of the quantity under the sign of the logarithm and use agreed units of measurement based on one or another system of physical units (SI, CGS, *etc.*).
