## Synthesis of polar polynorbornenes with high dielectric relaxation strength as candidate materials for dielectric applications†

Francis Owusu,<sup>a</sup> Martin Tress,<sup>c</sup> Frank A. Nüesch,<sup>b</sup> Sandro Lehner<sup>e</sup> and Dorina M. Opris<sup>b,a</sup>

Materials with high dielectric permittivity and dielectric relaxation strength are sought for thermal and pressure sensors and electrical energy generators. However, most polymers have either too low dielectric permittivity or are so polar that their glass transition temperature ( $T_g$ ) is too high and thus decomposition and side reactions occur before an electric field can polarize the polar groups. Here, we use the power and versatility of ring-opening metathesis polymerization (ROMP) to synthesize polar polymers with high dielectric relaxation strength and  $T_g$  significantly below the decomposition temperature. We first synthesized six polar norbornene monomers by conventional esterification, which were then polymerized by ROMP using Grubbs first- and third-generation catalysts. The structure of the polynorbornenes obtained were verified by multinuclear NMR spectroscopy, molecular weights determined by gel permeation chromatography (GPC), and thermal properties evaluated by thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC). Additionally, their dielectric permittivity, conductivity, and dielectric losses were measured at different temperatures and frequencies ranging between 0.1 and  $10^6$  Hz.

## Introduction

The design and synthesis of polymers responsive to different stimuli is a research field that gained significant attention from polymer chemists.<sup>1</sup> A large body of research has been focused on achieving polymeric materials that respond to pH, humidity, temperature, light, and magnetic field. However, little attention has been paid to the synthesis of electroactive polymers despite their potential in various applications.<sup>2</sup>

Electret polymers have a quasi-permanent polarization and respond to mechanical or thermal stress by generating an electric signal, and thus show piezo and pyroelectric effects.<sup>3</sup>

These effects were known, but a significant advancement in this field was achieved only when the piezoelectric response in polyvinylidene difluoride (PVDF) was discovered in 1969.<sup>4</sup> Since then, many applications for this polymer were found, which range from sensors, actuators, energy conversion to electronic devices.<sup>5,6</sup> However, PVDF is environmentally unfriendly and difficult to process. A further advancement in the field was achieved when small air voids in highly insulating polymer foams were polarized by corona discharge.<sup>7</sup> Such foams show a high piezoelectric response, but humidity negatively influences their performance.<sup>8</sup>

Quasi-permanent polarization can be introduced in amorphous polar polymers by poling in a strong electric field when heated above  $T_g$  and cooled below  $T_g$ .<sup>9</sup> Research in this direction attracted the attention of polymer chemists in the 1990s, as for example Hall Jr.,<sup>10</sup> Feast,<sup>11</sup> and Wegner.<sup>12</sup> Polyacrylonitrile and poly(vinylidenecyanide vinyl acetate) (PVVA) show a large dielectric relaxation strength ( $\Delta\epsilon$ ), but they are either environmentally unfriendly or have a high  $T_m$ . PVVA has amongst the highest  $\Delta\epsilon = 30$ .<sup>13</sup> While this is attractive, its very high  $T_g$  (170 °C) complicates the poling process due to possible thermal decomposition and side reactions. To achieve a practical piezoelectric response, polymers with as high as possible  $\Delta\epsilon$  are desirable. The dielectric relaxation strength is defined as the difference between the  $\epsilon_r$  and  $\epsilon_\infty$  and is related to the density of

polar groups ( $N$ ) and the dipole moment ( $\mu$ ). The polarization ( $P$ ) is given by

$$P = \varepsilon_0 \Delta\varepsilon(T) E_p \quad (1)$$

where  $\varepsilon_0$  is the vacuum permittivity,  $\Delta\varepsilon(T)$  the dielectric relaxation strength at the poling temperature, and  $E_p$  the poling field.

Polymers with large  $\Delta\varepsilon$  can be accessed by increasing the dipole density and dipole strength of polar groups grafted to the polymer chain. Polar groups can be introduced into a polymer chain either by post-polymerization modification or by polymerizing polar monomers. Ring-opening polymerization (ROMP) is a powerful tool for synthesizing polymers with different functional groups.<sup>14,15</sup> Norbornene-based monomers are predominantly employed due to their high ring strain, ensuring excellent polymerization propagation. Additionally, this monomer class can easily be modified with a wide range of functional groups, giving rise to polymers with otherwise inaccessible structures and properties.<sup>16,17</sup> Due to this versatility, polynorbornenes with pendant groups in the polymer backbone have recently spotlighted materials research. This is also due to the materials' attractive optical and electro-optic properties,<sup>18</sup> good mechanical and adhesive properties,<sup>19–21</sup> multi-shape memory effects,<sup>22</sup> and excellent dielectric behavior.<sup>23–28</sup> To increase the dielectric permittivity, functional moieties with large dipole moments as side chains have typically been considered.<sup>29</sup> For instance, Feast reported the synthesis of poly[2,3-bis(trifluoromethyl)norbornadiene] and its dielectric and pyroelectric properties.<sup>11</sup> Most recently, Bonard et al. reported on the synthesis of new poly(itaconate) polymers containing pendant sulfone and nitrile groups, which showed an interesting dielectric behavior in a broad temperature range, proving their potential as promising candidates for energy storage applications.<sup>30,31</sup>

There are only a few systematic experimental studies available on how different dipole moieties as pendant groups of polynorbornenes affect dielectric properties. Here, we report the synthesis of six polar norbornene monomers and their ROM polymerization. Furthermore, we report the thermal and dielectric properties of these polynorbornenes. Gratifyingly, some of these polymers show high  $\Delta\varepsilon$  and a  $T_g$  suitable for room temperature applications.

## Experimental

### Materials

All reagents were purchased from Sigma Aldrich and utilized without further purification unless otherwise stated. 2,6-Dimethyl-4H-pyran-4-one and 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) were acquired from ABCR GmbH and TCI Chemicals, respectively. Ethyl acetate, ethanol, methanol, heptane, dichloromethane (DCM), toluene, and tetrahydrofuran (THF) were purchased from VWR Chemicals and deuterated solvents from Deutero GmbH. *N*-Methyl-4-nitroaniline was synthesized according to the literature.<sup>32</sup> DCM was dried over calcium

hydride. Millipore Milli-Q system processed deionized water was taken for all experimental work-ups.

### Standard measurements and instrumentation

<sup>1</sup>H and <sup>13</sup>C NMR spectra were recorded on a Bruker Avance-400 spectrometer (400 MHz at room temperature) using CDCl<sub>3</sub> as a solvent if not otherwise stated. Mass spectra of monomers were obtained using a Bruker Daltonics HPLC-ESI-qTOF-MS spectrometer. Elemental analyses were conducted on a LECO TruSpec Micro and a LECO 628 O Micro employing IR spectroscopy as a detection unit.

The average molecular weights and polydispersity indices (PDI) of polymers were determined by two different gel permeation chromatography (GPC) systems with THF or hexafluoroisopropanol (HFIP) as eluents. The THF-based setup was equipped with Agilent 1260 Infinity, using two tandem-connected mixed-bed columns (1 × PLgel 5 μm MIXED-C Guard and 2 × PLgel 5 μm MIXED-C Analytical), coupled to a 390-MDS refractive index detector. Both systems employed a flow rate of 1 ml min<sup>−1</sup> and were kept at 35–40 °C. Polystyrene and poly(methyl methacrylate) were used as a calibration standard for the THF and HFIP eluent systems, respectively.

The thermal behavior of the synthesized polymers was investigated using a PerkinElmer DSC 8000 differential scanning calorimeter. The samples were initially heated to 150 °C at a rate of 20 °C min<sup>−1</sup> to remove any thermal history. Heat-cool-heat cycles were scanned from 0 to 200 °C at a rate of 20 °C min<sup>−1</sup>. For samples **PNBE-3** a heating-cooling-heating cycles from 0 to 150 °C at the rate of 20 °C min<sup>−1</sup> were used. Thermogravimetric analysis (TGA) was conducted using a PerkinElmer TGA7 at a heating rate of 10 °C min<sup>−1</sup> under a nitrogen gas flow.

Broadband dielectric spectroscopy (BDS) measurements were performed using a Novocontrol Alpha-A Frequency Analyzer equipped with quattro cryosystem temperature control. Samples were prepared by making pellets of the polymers with the aid of a hydraulic press, sandwiching between two metal electrodes with 100 μm glass fibres as spacers, and melt pressing in the 110 °C to 130 °C temperature range. Dielectric spectra were obtained by applying an external electric field of 10 kV m<sup>−1</sup> in a frequency and temperature range of 0.1 to 1 MHz and −100 to 160 °C, respectively.

### Synthetic methods

**Synthesis of 2-(1-(2-hydroxyethyl)-2,6-dimethylpyridin-4(1H)-ylidene)malononitrile.** 2,6-Dimethyl-4H-pyran-4-one (20.00 g, 161.1 mmol) and malononitrile (10.64 g, 161.1 mmol) were dissolved in acetic anhydride (80 ml) and the solution charged into a 200 ml round bottom flask. The reaction mixture was refluxed at 130 °C for 4 h to obtain crude **4H-PMal** intermediate (Scheme 1). The intermediate was purified by washing the unreacted acetic acid with warm water and recrystallizing from heptane to produce a dark brown powder (87% yield).

A 200 ml round bottom flask was charged with **4H-PMal** intermediate (15.00 g, 87 mmol), ethanolamine (44.7 ml, 745 mmol) and methanol (100 ml). The reaction was refluxed

**Scheme 1** Synthesis of monomers and respective homopolymers: (a) malononitrile, acetic anhydride, 4 h, reflux; (b) ethanolamine, methanol, 2 h, rf; (c) thionyl chloride, anhydrous chloroform 4 h, rf; (d) 4-dimethylaminopyridine, *N,N'*-dicyclohexylcarbodiimide, dry DCM, 24 h, 45 °C; (f) *N,N*-dimethylaniline, anhydrous chloroform, 13 h, 0 °C to rf; (g) Grubbs 1st or 3rd generation catalysts, dry DCM, 18 h, 40 °C.

at 70 °C for 2 h and then it was left to stand overnight. The separated solid was collected by filtration, dried, and recrystallized in ethanol to give compound **1** as brown flakes (yield 60%). <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) δ 6.68 (s, 2H, Ar-H), 5.17 (t, *J* = 5.4 Hz, 1H, OH), 4.17 (t, *J* = 5.6 Hz, 2H, N-CH<sub>2</sub>), 3.70 (q, *J* = 5.4 Hz, 2H, CH<sub>2</sub>-OH), 2.53 (s, 6H, Ar-CH<sub>3</sub>); <sup>13</sup>C NMR (DMSO-*d*<sub>6</sub>) δ 155.40 (C<sub>Ar</sub>=C(CN)<sub>2</sub>), 150.92 (C<sub>Ar</sub>-CH<sub>3</sub>), 119.43 (CN), 113.07 (C<sub>Ar</sub>-H), 59.76 (=C(CN)<sub>2</sub> and CH<sub>2</sub>-OH), 51.13 (N-CH<sub>2</sub>), 21.03 (Ar-CH<sub>3</sub>); MS (ESI) *m/z* calcd for C<sub>12</sub>H<sub>13</sub>N<sub>3</sub>NaO [M + Na]<sup>+</sup>: 238.0951; found: 238.0950; Anal. ### General preparation procedure for monomers (NBE-1 to NBE-4) via Steglich esterification

A dried 2-necked round bottom flask was charged with 5-norbornene-2-carboxylic acid (1 equiv.), functional alcohol **1–6** (1 equiv.), and 4-dimethylaminopyridine (2 equiv.) dissolved in anhydrous dichloromethane (60 ml). *N,N'*-Dicyclohexylcarbodiimide (DCC)/1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC) (2 equiv.) was added at 0 °C to the reaction mixture, which was then stirred for 5 min at 0 °C and refluxed for 24 h at 45 °C. The resulting crude mass was concentrated in a vacuum and purified *via* column chromatography eluting with heptane and ethyl acetate (3:2). (Fig. S7–S34, ESI<sup>†</sup>).

**NBE-1** was obtained as a light yellow powder (59% yield): <sup>1</sup>H NMR δ: 6.65 (s, 2H), 6.19 (ddd, *J* = 12.9, 5.7, 3.0 Hz, 1H), 5.96 (ddd, *J* = 117.3, 5.7, 3.0 Hz, 1H), 4.41–4.18 (m, 4H), 3.22–3.07 (m, 1H), 3.01–2.87 (m, 2H), 2.53 (s, 6H), 1.94 (ddd, *J* = 11.8, 9.4, 3.7 Hz, 1H), 1.52–1.25 (m, 3H). <sup>13</sup>C NMR (101 MHz, Chloroform-*d*) δ 175.78, 174.23, 156.07, 147.86, 147.84, 138.42, 138.31, 135.38, 131.80, 118.36, 113.85, 113.83, 61.17, 61.07, 49.74, 46.83, 46.74, 46.53, 46.36, 45.72, 43.17, 42.85, 42.48, 41.59, 30.59, 29.41, 21.01, 20.99. ### General preparation procedure for monomers NBE-5 and NBE-6

A dried 2-necked round bottom was charged with the respective functional alcohol (2 equiv.), and *N,N*-dimethylaniline (2 equiv.). 5-Norbornene-2-carbonyl chloride (1 equiv.) was diluted with 15 ml of dry chloroform and added over 15 min to the reaction vessel at 0 °C. The mixture was then stirred at RT for 1 h and further heated to reflux for another 12 h. The reaction was then quenched by adding 10 ml of 6N H<sub>2</sub>SO<sub>4</sub>. Afterward, the organic phase was separated and the aqueous phase extracted thrice

with DCM. The collected organic phases were combined, washed with 6 ml of 6N H<sub>2</sub>SO<sub>4</sub>, followed by further washing with 2 × 20 ml deionized water, 2 × 20 ml conc. NaHCO<sub>3</sub> and 20 ml of brine solution. The crude product in the solution was dried over anhydrous Na<sub>2</sub>SO<sub>4</sub> and then vacuum evaporated. Finally, the product was purified by column chromatography eluting with heptane and ethyl acetate (3 : 2). (Fig. S35–S44, ESI†).

**NBE-5** was obtained as a colourless liquid (81% yield): <sup>1</sup>H NMR δ: 6.21 (ddd, *J* = 22.6, 5.7, 3.0 Hz, 1H), 6.03 (ddd, *J* = 66.8, 5.7, 3.0 Hz, 1H), 4.60–4.43 (m, 2H), 3.39–3.28 (m, 2H), 3.22 (dq, *J* = 3.6, 2.0 Hz, 1H), 3.09–2.98 (m, 1H), 3.02 (s, 3H), 2.98–2.93 (m, 1H), 2.01–1.88 (m, 1H), 1.56–1.36 (m, 2H), 1.34–1.25 (m, 1H). <sup>13</sup>C NMR δ 175.57, 174.02, 138.29, 138.24, 135.51, 132.01, 57.83, 57.70, 54.04, 49.72, 46.50, 46.40, 45.77, 43.21, 42.94, 42.54, 42.30, 42.27, 41.63, 30.50, 29.31. **NBE-6** was obtained as a colourless liquid (89% yield): <sup>1</sup>H NMR δ 6.20 (ddd, *J* = 23.0, 5.7, 3.0 Hz, 1H), 6.06 (ddd, *J* = 60.4, 5.7, 2.9 Hz, 1H), 4.35–4.18 (m, 2H), 3.27 (dq, *J* = 3.8, 2.1 Hz, 1H), 3.11–2.98 (m, 1H), 2.98–2.91 (m, 1H), 2.72 (dt, *J* = 16.1, 6.3 Hz, 2H), 2.00–1.90 (m, 1H), 1.55–1.38 (m, 2H), 1.31 (dt, *J* = 8.2, 1.6 Hz, 1H). <sup>13</sup>C NMR δ: 175.77, 174.25, 138.20, 138.11, 135.61, 132.18, 116.89, 116.86, 58.59, 58.47, 49.72, 46.71, 46.36, 45.79, 43.17, 42.95, 42.55, 41.67, 30.41, 29.24, 18.10, 18.08. MS (ESI) *m/z* calcd for C<sub>11</sub>H<sub>13</sub>NNaO<sub>2</sub> [M + Na]<sup>+</sup>: 214.0838; found: 214.0839. Refractive index: 1.482; density: 1.133.

### General procedure for ring-opening metathesis polymerization (ROMP)

Polymers were prepared *via* ROMP using Grubbs 1st or 3rd generation catalysts, as shown in Scheme 1 below. A 2-necked round bottom flask was charged with the respective monomer **NBE-X** and DCM. For quantities, see Table 1. The system was initially degassed by two freeze–vacuum–thaw cycles followed by the addition of the catalyst while frozen and a third degassing. The reaction was run under argon and at 40 °C for 18 h. After confirming total monomer conversion by TLC, ethyl vinyl ether was added, and the resulting mixture stirred for a further 1 h. The product mixture was concentrated under vacuum and then precipitated into excess methanol. The polymer was further purified by five consecutive dissolution (DCM) and re-precipitation cycles (MeOH). The obtained polymers were dried to constant weight under vacuum at 50 °C.

**PNBE-2** was obtained as a green solid (98% yield). <sup>1</sup>H NMR (DMSO) δ: 7.94 (br s, 2H), 6.71 (br s, 2H), 5.01 (br d, *J* = 45.8 Hz, 2H), 4.09 (br d, *J* = 68.8 Hz, 2H), 3.66 (br s, 2H), 2.99 (br s, 3H), 2.93–2.16 (br m, 3H), 2.07–0.55 (br m, 4H). <sup>13</sup>C NMR (DMSO) δ: 175.03, 174.00, 154.02, 136.30, 134.54, 133.51, 132.71, 130.76, 129.51, 126.09, 111.07, 61.23, 50.41, 48.10, 44.95, 42.27, 38.88, 37.49, 36.38. ## Results and discussion

The synthesis of different polar norbornene monomers (**NBE-X**) is outlined in Scheme 1. Monomers **NBE-1** to **NBE-4** were

prepared by an esterification reaction with 5-norbornene-2-carboxylic acid, a mixture of endo and exo, whereas monomers **NBE-5** and **NBE-6** were obtained by esterification reaction of 5-norbornene-2-carboxylic acid chloride, respectively. Monomers were purified by column chromatography over silica gel to achieve a mixture of 80% endo and 20% exo-products according to the integration of the olefinic protons in the  $^1\text{H}$  NMR spectra. The structure of all monomers was confirmed by  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectroscopy, MS spectrometry, and elemental analysis (Fig. S1–S44, ESI†).

Homopolymerization of **NBE-X** was carried out with Grubbs I and III catalysts in DCM at 40 °C for 18 h. Ethyl vinyl ether was used as a quencher. The polymers were isolated in yields of over 90%. Clear evidence for polymerization is provided by  $^1\text{H}$  NMR spectroscopy images of the vinylene groups. While those of the monomers appear at  $\delta = 5.8\text{--}6.5$  ppm those of the polymer absorb at  $\delta = 5.4$  ppm. Additionally, all signals of the polymers are broadened. Fig. 1 shows representative  $^1\text{H}$  NMR spectra of monomer **NBE-3** and of polymer **PNBE-3**. Because the molecular weights of the prepared polymers were relatively high, end groups could not be detected in the  $^1\text{H}$  NMR spectra. It must be stated that the polymerization of the **NBE-1** monomer was unsuccessful. A possible reason might be the stabilization of

the reactive metal–carbene complex center by this monomer, thereby inhibiting the polymerization propagation step.

The polymerizations were conducted using varying monomer/catalyst ratios (Table 1). The molecular weights ( $M_n$ ) and polydispersities (PDI) were determined by GPC in THF, HFIP, or 20 mM sodium trifluoroacetate solution in HFIP using polystyrene and poly(methyl methacrylate) standards (Table 1). Fig. 2a shows the GPC elugrams of **PNBE-3** of different molecular weights. For all other elugrams see the ESI.† The molecular weights of the polymers increased with increasing monomer/catalyst ratio. The molecular weights calculated based on the ratio of monomer to catalyst are generally higher than those measured by GPC, which is expected as the GPC is a relative method and the standards used for calibration have a different chemical structure. Some polymers show bimodality, presumably due to chain transfer reactions in the later stage of the polymerization.

The thermal behavior of **PNBE-X** was investigated by differential scanning calorimetry (DSC) and thermogravimetric analysis (TGA) (Fig. 2b and c, Fig. S60–S69, ESI†). All polymers are amorphous and show a  $T_g$ . Fig. 2b shows the DSC curves of polymers **PNBE-X**. The corresponding  $T_g$  and  $\Delta C_p$  values of the transitions are listed in Table 2. The lowest  $T_g$  of 62 °C was measured for **PNBE-6** that carries nitrile groups, while the highest  $T_g$  of 106 °C was measured for **PNBE-3**, which has *N*-ethyl-*N*-(2-hydroxyethyl)-4-(4-nitrophenylazo)aniline (disperse red 1) as a dipole. TGA was carried out to test the thermal stability and decomposition behavior. Polymers **PNBE-2**, **PNBE-4**, and **PNBE-5** turned out to be stable up to a temperature of 290 °C (Fig. 2c), while polymers **PNBE-6** and **PNBE-3** decompose above 200 °C. The molecular weight of the polymers has a negligible impact on thermal behavior, which indicates that the synthesized polymers are in the polymeric regime, where the  $T_g$  is molecular weight independent.

Broadband dielectric spectroscopy (DBS) was applied at temperatures between –100 °C and 140 °C to identify the type of mobile segments in the polymers and elucidate the dynamic changes. The measurements were conducted in capacitor geometry, where 100  $\mu\text{m}$  thick films of **PNBE-X** were placed between two metal electrodes with a diameter of 20 mm. The **PNBE-X** polymers show several relaxation processes within the

Fig. 1  $^1\text{H}$  NMR spectra in  $\text{CDCl}_3$  of monomer **NBE-3** (top) and its corresponding polymer **PNBE-3** (bottom).

**Fig. 3** Isothermal dielectric response of **PNBE-2** as a function of frequency; (a) real permittivity  $\epsilon'$ , (b) dielectric loss  $\epsilon''$ , (c) real conductivity  $\sigma'$  and (d) loss  $\tan \delta$ .

set temperature range. Fig. 3 gives an illustration of how the real part  $\epsilon'$  and imaginary part  $\epsilon''$  of the complex permittivity, the real part of the conductivity  $\sigma'$  and the loss tangent  $\tan \delta$  evolve with the temperature at different frequencies for **PNBE-2**. Generally, there is a noticeable increase in  $\epsilon'$  with increasing temperature over the specified frequency range, as shown in Fig. 3a. However, the  $\epsilon'$  remains virtually constant from  $-60$  °C to  $70$  °C because the orientation motions are restricted to small angles. Above  $70$  °C the increment becomes very pronounced, which is attributed to the thermal activation of the dipole motions in the polymer. Thus, the presence of pendant dipolar moieties on the polymer chains experiences enough

hindrances, which impose potential energy barriers to their mobility below certain temperatures. Such energy impositions are dependent on the packing density, the intrinsic chain flexibility, rotational restrictions, softness of potential related to angle changes, and the intra- and intermolecular dipole interactions.<sup>31,33</sup>

Adding enough thermal energy to the system helps overcome these energy barriers, and segmental rotation allows reorientation of the dipoles reflected in an increased polarization. Thus, the orientation polarization of the dipoles occurs above  $T_g$ . The relaxation peak for the orientation polarization process is shifted to higher frequencies with increasing temperature. Above  $100$  °C, the ionic conductivity contributes to the increase in dielectric permittivity at low frequencies. This is also supported by the dielectric loss, which shows an increase at low frequencies with a slope approximation of  $-1$  and a sudden increase in the conductivity of the material, as shown in Fig. 3b–d. The temperature increases the ionic conductivity and shifts this process to higher frequencies.

To relate the bulk dielectric behavior of PNBE-X polymers with respect to structural and molecular motions of their dipolar segments, an approximation was made by fitting the experimental data with a Havriliak–Negami (HN) relaxation function. This was achieved through fitting isothermal data of  $\epsilon''$  by a superposition of the HN-function and a conductivity contribution as shown in eqn (2) below<sup>34</sup>

$$\epsilon'' = \frac{\sigma_0}{\epsilon_0} \frac{a}{\omega^s} + \text{Im} \left[ \frac{\Delta\epsilon}{(1 + (i\omega\tau)^\alpha)^\gamma} \right] \quad (2)$$

where  $\epsilon''$  is the imaginary permittivity,  $\sigma_0$  is the d.c.-conductivity,  $a$  is a constant,  $\epsilon_0$  the permittivity of vacuum,  $\omega = 2\pi f$  the angular frequency,  $\Delta\epsilon$  the dielectric relaxation strength,  $\tau$  the relaxation time,  $\alpha$  and  $\gamma$  describe the symmetric and asymmetric broadening of the relaxation peak,  $i$  the imaginary unit ( $i = \sqrt{-1}$ ). The exponent  $s < 1$  are observed for ionic charge carriers, which cause electrode polarisation. The parameters of relevance to understand the dynamic transitions taken place at the molecular level and the possibility to polarize these polymers are  $\tau$  and  $\Delta\epsilon$ .

Generally, two distinct regimes revealing molecular motions responsible for  $\alpha$ - and  $\beta$ -relaxation processes in glass-forming materials were easily fitted, as illustrated in Fig. 4a. Complete sets of fits for all polymers can be found in the ESI† (Fig. S70–S82). The relaxation times for the  $\beta$ -processes, as shown in Fig. 4b, exhibit Arrhenius temperature dependences over the

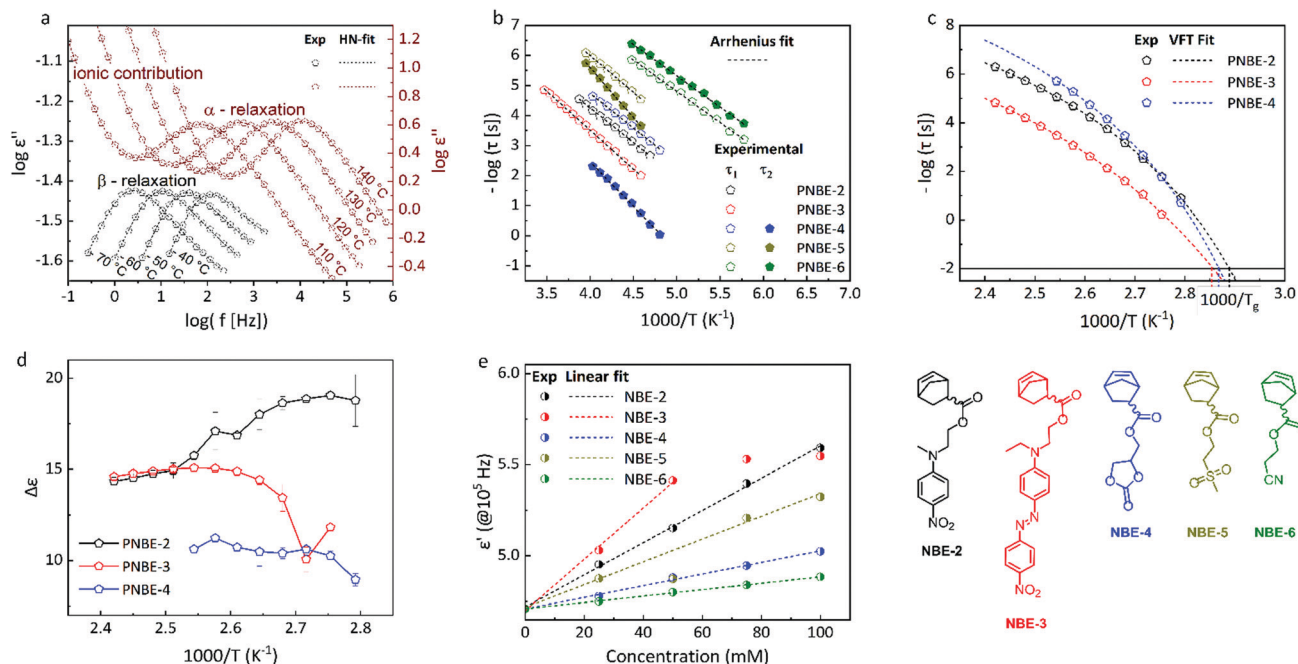

Fig. 4 Dielectric relaxation of PNBE-X polymers and the dipolar dynamics of their respective monomers; (a) isothermal illustration of the imaginary part  $\epsilon''$  of the complex dielectric function vs. frequency for two temperature regimes; below  $T_g$  ( $\beta$ -relaxation) and above  $T_g$  ( $\alpha$ -relaxation) for **PNBE-3**; (b) Arrhenius fitting of  $\beta$ -relaxation mechanisms for PNBE-X; (c) VFT plot of  $\alpha$ -relaxation processes for **PNBE-2**, **PNBE-3**, and **PNBE-4**; and (d) temperature dependence of dielectric relaxation strength for **PNBE-2**, **PNBE-3**, and **PNBE-4** in the  $\alpha$ -relaxation regime; (e) dielectric permittivity as a function of concentration for NBE-X in chloroform. From the slopes the respective dipole moments were calculated.

temperature range in which the process is resolvable. The Arrhenius fits describe the experimentally determined relaxation times. The activation energies, which depend on both internal rotational barriers and the environment of the dipolar fluctuating unit, obtained from the fitting for the PNBE-X polymers are listed in Table 2. In contrast, the  $\alpha$ -relaxation processes for PNBE-X polymers exhibit clear non-Arrhenius temperature dependencies, well represented by a Vogel–Fulcher–Tammann (VFT) fit function with parameters in good agreement with experimental values as shown in Fig. 4c. The degree of deviation from an Arrhenius-type temperature dependence provides a useful classification of glass-forming systems. Additionally, at the calorimetric glass transition temperature  $T_g$ , the  $\alpha$ -relaxation reaches a peak frequency approximated to  $10^{-3}$  Hz.<sup>34</sup> The  $T_g$  of glass-forming materials can be extrapolated from the  $\alpha$ -relaxation processes obeying a VFT-temperature dependence. As a result, the  $T_g$  for **PNBE-2**, **PNBE-3**, and **PNBE-4** could be estimated by DBS techniques as listed in Table 2. While the  $\beta$ -processes are believed to be due to localized motions of the pendant dipolar moieties, the  $\alpha$ -processes are attributed to segmental relaxations of the polymer chains. For amorphous polymers,  $\Delta\epsilon$  is said to decrease with increasing temperature above  $T_g$ .<sup>34</sup> Fig. 4d shows the temperature dependence of  $\Delta\epsilon$  for **PNBE-2**, **PNBE-3**, and **PNBE-4** polymers within the  $\alpha$ -relaxation regime. This temperature dependency was more pronounced in **PNBE-2** polymer than in the **PNBE-3** and **PNBE-4** polymers. The maximum dielectric relaxation strengths were estimated to be 19.06, 15.08, and 11.24 for **PNBE-2**, **PNBE-3**, and **PNBE-4**, respectively. For **PNBE-5** and

**PNBE-6** we could not assess the relaxation strength because of the high ionic conductivity of the samples.

To clarify the observed trend in dielectric relaxation strengths  $\Delta\epsilon$  of PNBE-X polymers, the molecular dipole moments of the corresponding NBE-X monomers were evaluated experimentally. The  $\Delta\epsilon$  is proportional to the dipole moments of contributing dipolar units within a material.<sup>34</sup> The dipole moments of NBE-X were determined from dielectric spectroscopy measurements of solutions of NBE-X in chloroform at ambient temperature and  $10^5$  Hz. To avoid dipolar interactions, dilute solutions of the monomers in chloroform were prepared. The dielectric permittivity was measured as a function of solute concentration, as shown in Fig. 4e. Dipole moments were thereafter estimated by modified Onsager equation according to Böttcher<sup>35,36</sup> and a model according to Hedestrand–Guggenheim–Smith.<sup>37,38</sup> The obtained results are listed in Table 3. For the equations used, please see ESI.† The dipole

Table 3 Dipole moments of NBE-X determined by Hedestrand–Guggenheim–Smith (HGS) model and Böttcher model

<b>NBE-6</b>	1.133	1.482	3.00 ± 0.42	7.07 ± 1.63

moment was obtained from the slope of  $\epsilon'$  versus molar concentration (Fig. 4e). As expected, the highest dipole moment was found for **NBE-1**, but this monomer did not polymerize (Table 3). The second highest dipole was found for **NBE-3**. However, this high dipole moment is not reflected in the relaxation strength of **PNBE-3**, which was lower than for **NBE-2**, which has a lower dipole moment. The low relaxation strength of **PNBE-3** may be related to the different dipole moments of *cis-trans* isomers of disperse red 1 or the antiparallel orientation of the dipoles, which is likely favored by the  $\pi$ - $\pi$  interactions.

## Conclusions

Six polar norbornene monomers were synthesized and five of them were successfully polymerized by ROMP using Grubbs I and III generation catalysts. The molecular weight of the polymers, as revealed by GPC, show increasing correlation with the theoretical monomer-to-catalyst feed ratio. The synthesized polymers show moderate room temperature dielectric permittivity, which is typical for high  $T_g$  polar glassy polymers. All polymers show an increase in the dielectric relaxation strength at temperatures above the  $T_g$ . Because of their high dielectric relaxation strength, we propose the novel polymers to be useful as electrets and to find applications in thermal sensors and thermal energy harvesting. Work in this direction is underway.

## Author contributions

F. O. conducted all experimental work and recorded the impedance spectroscopy data as well as the fittings of the dielectric data. D. M. O. initiated the work, raised the funding, and supervised the research. M. T. supported the interpretation of the dielectric measurements. F. N. supported the calculations of the dipole moment. S. L. supported the GPC measurements. All authors contributed to scientific discussions. F. O. and D. M. O. wrote the manuscript with input from all authors.
