Facile growth of a  $\text{Sb}_2\text{Se}_3$  nanorods array induced by a  $\text{MoSe}_2$  interlayer and its application in 3D p-n junction solar cells

Co-evaporation process was used to deposit uniformly grown  $\text{Sb}_2\text{Se}_3$  nanorods array using a  $\text{MoSe}_2$  interlayer. The  $\text{MoSe}_2$  interlayer acted as a crucial role as a seed layer for the preferential growth of the  $\text{Sb}_2\text{Se}_3$  nanorods and also improved the contact quality between the  $\text{Sb}_2\text{Se}_3$  nanorods array and a Mo substrate. The application of the  $\text{Sb}_2\text{Se}_3$  nanorods array to 3D p-n junction high-efficiency  $\text{Sb}_2\text{Se}_3$  solar cells was also presented.

# Facile growth of a $\text{Sb}_2\text{Se}_3$ nanorod array induced by a $\text{MoSe}_2$ interlayer and its application in 3D p–n junction solar cells†

Si-Nae Park,<sup>‡a</sup> Se-Yun Kim,<sup>‡b</sup> Sang-Ju Lee,<sup>ac</sup> Shi-Joon Sung,<sup>id \*ac</sup>  
Kee-Jeong Yang,<sup>id ac</sup> Jin-Kyu Kang,<sup>id ac</sup> and Dae-Hwan Kim,<sup>id \*ac</sup>

A uniformly grown  $\text{Sb}_2\text{Se}_3$  nanorod array, with the introduction of a  $\text{MoSe}_2$  interlayer, obtained by a co-evaporation process and its application in three-dimensional (3D) p–n junction high-efficiency  $\text{Sb}_2\text{Se}_3$  solar cells were investigated in this study. The  $\text{MoSe}_2$  interlayer played a crucial role as a seed layer for the preferential growth of  $\text{Sb}_2\text{Se}_3$  crystals, which facilitated the formation of a  $\text{Sb}_2\text{Se}_3$  nanorod array regardless of the process conditions. 3D p–n junction between the  $\text{Sb}_2\text{Se}_3$  nanorod array and the CdS buffer layer improved the short-circuit current of  $\text{Sb}_2\text{Se}_3$  solar cells due to improved carrier transportation from the  $\text{Sb}_2\text{Se}_3$  absorber to the CdS buffer. The  $\text{MoSe}_2$  interlayer also improved the contact quality between the  $\text{Sb}_2\text{Se}_3$  nanorod array and the Mo substrate by forming a quasi-ohmic contact, which resulted in a higher open-circuit voltage due to a reduced contact barrier and series resistance in  $\text{Sb}_2\text{Se}_3$  solar cells. The crystal growth rate of  $\text{Sb}_2\text{Se}_3$  was controlled by the source evaporation rate and substrate temperature to tune the final nanostructure and crystalline orientation of the co-evaporated  $\text{Sb}_2\text{Se}_3$  nanorods array. 3D p–n junction solar cells based on an ordered and ( $hk1$ ) preferentially oriented  $\text{Sb}_2\text{Se}_3$  nanorod array showed a power conversion efficiency of 5.637%. Therefore, by including a  $\text{MoSe}_2$  interlayer, it is possible to achieve high-efficiency 3D p–n junction  $\text{Sb}_2\text{Se}_3$  solar cells.

## Introduction

Antimony selenide ( $\text{Sb}_2\text{Se}_3$ ) is one of the most promising semiconductor materials for thin-film solar cells because of its outstanding optoelectronic properties. Additionally, it is a non-toxic, relatively low-cost material with high absorption coefficient and low processing temperature.<sup>1–6</sup> Therefore, significant research has been conducted in the past decade to replace the conventional multinary compound semiconductors in thin-film solar cells for  $\text{Sb}_2\text{Se}_3$ .<sup>7–11</sup> However, the best power conversion efficiency (PCE) reported so far for  $\text{Sb}_2\text{Se}_3$  solar cells is approximately 10%,<sup>12</sup> which is similar to those of thin-film solar cells made of conventional materials. In order to overcome the efficiency limitation of the  $\text{Sb}_2\text{Se}_3$  solar cells, the application of three-dimensional (3D) nanostructured  $\text{Sb}_2\text{Se}_3$

thin films for the formation of the 3D p–n junction solar cells could be one of the promising solutions.<sup>13–15</sup>

Carrier transportation and p–n junction formation in  $\text{Sb}_2\text{Se}_3$  solar cells are closely related to the  $\text{Sb}_2\text{Se}_3$  nanostructure. Therefore, the latter is one of the critical factors determining the photovoltaic performance of  $\text{Sb}_2\text{Se}_3$  solar cells. However, there is little study on the nanostructure control of the  $\text{Sb}_2\text{Se}_3$  thin films for high efficiency solar cells. Li *et al.* improved the short-circuit current ( $J_{sc}$ ) of a solar cell using a 1000 nm-high  $\text{Sb}_2\text{Se}_3$ -nanorod array with superior light-harvesting capacity and reduced optical reflection.<sup>16</sup> In our previous work, we investigated the evolution of  $\text{Sb}_2\text{Se}_3$  nanorods by controlling the process temperature of co-evaporation and proposed the photovoltaic performance enhancement of  $\text{Sb}_2\text{Se}_3$  solar cells based on 3D p–n junction formation.<sup>18</sup> However, the temperature window for the formation of  $\text{Sb}_2\text{Se}_3$  nanorods was narrow and the orientation of the  $\text{Sb}_2\text{Se}_3$  nanorods was random. From these previously reported studies, it was found that the application of 3D nanostructured  $\text{Sb}_2\text{Se}_3$  absorber layers would be very useful to overcome of the performance limitation of  $\text{Sb}_2\text{Se}_3$  solar cells based on the 3D p–n junction solar cell concept. However, to the best of the authors' knowledge, there is no detailed investigation of the nanostructure evolution of  $\text{Sb}_2\text{Se}_3$  thin films reported in the literature.

‡ These authors contributed equally to this paper.

The objective of this work was to study the evolution of a nanostructured  $\text{Sb}_2\text{Se}_3$  thin film fabricated using a  $\text{MoSe}_2$  interlayer and the co-evaporation process. Additionally, a detailed investigation of the controlling factor to achieve fine-tuned  $\text{Sb}_2\text{Se}_3$  nanorod arrays is presented in this work. In our work, we proposed the evolution of nanostructured  $\text{Sb}_2\text{Se}_3$  thin films using a  $\text{MoSe}_2$  interlayer and detailed investigation on the control factor of the co-evaporation process for the fine-tuning of the  $\text{Sb}_2\text{Se}_3$  nanorod array. By introducing a  $\text{MoSe}_2$  interlayer between the Mo substrate and  $\text{Sb}_2\text{Se}_3$ , it was possible to form uniformly ordered packed  $\text{Sb}_2\text{Se}_3$  nanorod formation using co-evaporation of  $\text{Sb}_2\text{Se}_3$  and Se sources. The  $\text{MoSe}_2$  interlayer has locally distributed dangling bonds, which play the role of nucleation seed for  $\text{Sb}_2\text{Se}_3$  crystalline growth perpendicular to the Mo substrate. Because of the seeding effect of the  $\text{MoSe}_2$  interlayer,  $\text{Sb}_2\text{Se}_3$  thin films deposited on the  $\text{MoSe}_2$  interlayer dominantly showed a uniformly ordered packed  $\text{Sb}_2\text{Se}_3$  nanorod array. In addition, the formation of a quasi-ohmic contact between  $\text{Sb}_2\text{Se}_3$  and  $\text{MoSe}_2$  was another improving point of open-circuit voltage ( $V_{\text{OC}}$ ) of  $\text{Sb}_2\text{Se}_3$  solar cells compared with  $\text{Sb}_2\text{Se}_3$  solar cells without the  $\text{MoSe}_2$  interlayer.

The nanostructure of the  $\text{Sb}_2\text{Se}_3$  nanorod arrays on the  $\text{MoSe}_2$  interlayer was also sensitively affected by the conditions of the co-evaporation processes, such as the evaporation rate of sources and substrate temperature. The growth behavior of  $\text{Sb}_2\text{Se}_3$  crystals during the co-evaporation process was closely related with the final nanostructure of  $\text{Sb}_2\text{Se}_3$  nanorod array, which was the main factor that determines the short-circuit current ( $J_{\text{SC}}$ ) of  $\text{Sb}_2\text{Se}_3$  solar cells. The crystalline orientation of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films, which is a crucial factor for high efficiency  $\text{Sb}_2\text{Se}_3$  solar cells, was also affected by the substrate temperature.<sup>18–25</sup> After chemical bath deposition (CBD) of n-type CdS buffer layers on the  $\text{Sb}_2\text{Se}_3$  nanorod array, the 3D p–n junction between  $\text{Sb}_2\text{Se}_3$  and CdS was formed and the 3D p–n junction was effective for the enhancement of  $J_{\text{SC}}$ . By introducing the  $\text{MoSe}_2$  interlayer, the growth of a uniformly ordered  $\text{Sb}_2\text{Se}_3$  nanorod array and the quasi-ohmic contact between  $\text{Sb}_2\text{Se}_3$  and  $\text{MoSe}_2$  were possible and 3D p–n junction  $\text{Sb}_2\text{Se}_3$  solar cells with 5.637% efficiency was achieved.

## Experimental

### $\text{MoSe}_2$ interlayer and $\text{Sb}_2\text{Se}_3$ thin-film preparation

The structure of the studied  $\text{Sb}_2\text{Se}_3$  thin films consisted of a soda-lime glass (SLG) substrate and a 600 nm-thick Mo layer as the back-contact layer. Before deposition, the substrate was sequentially cleaned in an ultrasonic bath using acetone, methanol, and deionized water. The Mo layer was deposited on the SLG substrate *via* direct current (DC) magnetron sputtering using a Mo target with a purity of 99.99%.

To form the  $\text{MoSe}_2$  interlayer on Mo substrates, the latter were treated in a tube furnace in a Se atmosphere. Vacuum ( $10^{-3}$  Torr) was applied to the furnace to remove moisture and impurities. Then, Ar gas was introduced into the furnace, allowing the pressure inside the furnace to reach the

atmospheric pressure. The furnace was heated to 430 °C with Se pellets inside for 10 min and then annealed for 10 min. The  $\text{MoSe}_2$  layer obtained was approximately 100 nm-thick.

The  $\text{Sb}_2\text{Se}_3$  thin films were prepared on bare Mo substrates or  $\text{MoSe}_2/\text{Mo}$  substrates using a co-evaporator system using  $\text{Sb}_2\text{Se}_3$  and Se sources. The substrate temperature was controlled in the range of 250–290 °C. The substrate was heated at  $0.53 \text{ }^\circ\text{C s}^{-1}$  from room temperature ( $\sim 25 \text{ }^\circ\text{C}$ ) to the desired temperature. The evaporation rate of  $\text{Sb}_2\text{Se}_3$  and Se sources varied from 50–200  $\text{\AA s}^{-1}$ .  $\text{Sb}_2\text{Se}_3$  was deposited to obtain thin films (thickness: approximately 500 nm). After deposition, the samples were allowed to cool to room temperature naturally.

### Solar cell fabrication

Chemical bath deposition (CBD) was used to cover the  $\text{Sb}_2\text{Se}_3$  thin films obtained with a 50 nm-thick n-type cadmium sulfide (CdS) buffer layer, and radiofrequency (RF) sputtering was used to sequentially deposit a 50 nm-thick intrinsic ZnO window layer and a 300 nm-thick Al-doped ZnO (AZO) A transparent conducting oxide (TCO) layer was deposited on top of the buffer layer to fabricate the solar cells. Thermal evaporation was then used to deposit a 1  $\mu\text{m}$ -thick Al collection grid on top of the device.

### Characterization of $\text{Sb}_2\text{Se}_3$ solar cells

The  $\text{Sb}_2\text{Se}_3$  thin films were analyzed using various techniques to determine the influence of substrate temperature on the chemical composition and morphology of the films, and consequently, on the photovoltaic characteristics of the  $\text{Sb}_2\text{Se}_3$  solar cells. The surface morphology and chemical composition of the  $\text{Sb}_2\text{Se}_3$  thin films were observed using field emission scanning electron microscopy (FE-SEM, Hitachi, SU8020) and transmission electron microscopy (FE-TEM, Hitachi, HF-3300) with a focused ion beam (FIB) system (Hitachi, NB 5000). The crystalline structure of the  $\text{Sb}_2\text{Se}_3$  thin films was determined using X-ray diffraction (XRD) analysis (Panalytical, Empyrean). The photovoltaic characteristics of the solar cells were characterized using a source meter (Keithley, 2400) unit and a solar simulator (Newport, 94022A) to simulate 1.5AM solar irradiation.

## Results and discussion

To obtain a controlled  $\text{Sb}_2\text{Se}_3$  crystalline structure in  $\text{Sb}_2\text{Se}_3$  solar cells, an  $\text{MoSe}_2$  interlayer between the  $\text{Sb}_2\text{Se}_3$  absorber and the Mo substrate was adopted. Additionally, the  $\text{MoSe}_2$  interlayer between  $\text{Sb}_2\text{Se}_3$  and the Mo substrate played an important role in the growth control of the  $\text{Sb}_2\text{Se}_3$  crystalline structure. To investigate the role and effect of the  $\text{MoSe}_2$  interlayer on  $\text{Sb}_2\text{Se}_3$  crystal growth,  $\text{Sb}_2\text{Se}_3$  thin films were deposited on bare Mo substrates and  $\text{MoSe}_2/\text{Mo}$  substrates using the co-evaporation process at different source evaporation rates (50–200  $\text{\AA s}^{-1}$ ). The source evaporation rate is closely related to the  $\text{Sb}_2\text{Se}_3$  crystal growth mechanism. Fig. 1 shows

**Fig. 1** Top and cross-sectional SEM images of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on bare Mo substrates or  $\text{MoSe}_2/\text{Mo}$  substrates at  $290^\circ\text{C}$  and different source evaporation rates: (a),  $50 \text{ \AA s}^{-1}$ ; (b),  $100 \text{ \AA s}^{-1}$ ; and (c),  $200 \text{ \AA s}^{-1}$  on bare Mo substrates; and (d),  $50 \text{ \AA s}^{-1}$ ; (e),  $100 \text{ \AA s}^{-1}$ ; and (f),  $200 \text{ \AA s}^{-1}$  on  $\text{MoSe}_2/\text{Mo}$  substrates.

the cross-sectional SEM images of  $\text{Sb}_2\text{Se}_3$  thin films with different substrates and at different evaporation rates.

In the case of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on bare Mo substrates, thin films deposited at a slow source evaporation

rate ( $50 \text{ \AA s}^{-1}$ ) showed a small and randomly oriented  $\text{Sb}_2\text{Se}_3$  nanorod structure (Fig. 1a). However, as the source evaporation rate increased to  $100 \text{ \AA s}^{-1}$ ,  $\text{Sb}_2\text{Se}_3$  thin films showed a densely packed columnar structure with some long  $\text{Sb}_2\text{Se}_3$  nanorods (Fig. 1b). At a source evaporation rate of  $200 \text{ \AA s}^{-1}$ , a flat  $\text{Sb}_2\text{Se}_3$  thin-film structure comprising densely packed grains was observed (Fig. 1c). Generally, the nucleation rate is closely related to the evaporation rate.<sup>26</sup> Thus, a easily formed continuous film under a high evaporation rate was expected. For film materials having an anisotropic crystal structure, such as  $\text{Sb}_2\text{Se}_3$ , rod-shaped film formation is highly probable when the evaporation rate is low. Under these conditions, the impingement rate of adatoms on the substrate decreases and their diffusion length may increase, causing the formation of a non-continuous film. Based on these results, authors believe that controlling the evaporation rate is critical to developing the  $\text{Sb}_2\text{Se}_3$  rod array for 3D p-n junction solar cells.

Contrary to the co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on Mo substrates,  $\text{Sb}_2\text{Se}_3$  thin films prepared on  $\text{MoSe}_2/\text{Mo}$  substrates showed a different nanostructure. All  $\text{Sb}_2\text{Se}_3$  thin films on  $\text{MoSe}_2/\text{Mo}$  substrates showed non-flat thin-film structures, regardless of the source evaporation rate. At an evaporation rate of  $50 \text{ \AA s}^{-1}$ , thin films showed a vertically oriented narrow  $\text{Sb}_2\text{Se}_3$  nanorod array of length  $500 \text{ nm}$  (Fig. 1d). The diameter and length of the  $\text{Sb}_2\text{Se}_3$  nanorods increased with increasing evaporation rate from  $50$  to  $100 \text{ \AA s}^{-1}$  (Fig. 1e). At an evaporation rate of  $200 \text{ \AA s}^{-1}$ , the thin-film showed ordered arrays of thick  $\text{Sb}_2\text{Se}_3$  nanorods with a diameter of  $100 \text{ nm}$  (Fig. 1f).  $\text{Sb}_2\text{Se}_3$  thin films deposited on  $\text{MoSe}_2$  substrates showed a  $\text{Sb}_2\text{Se}_3$  nanorod array structure regardless of the source evaporation rate. Additionally, the  $\text{Sb}_2\text{Se}_3$  nanorod array nanostructure was tuned by varying the source evaporation rate. The formation of  $\text{Sb}_2\text{Se}_3$  nanorod array on the  $\text{MoSe}_2$  interlayer might be attributed to different  $\text{Sb}_2\text{Se}_3$  crystal growth mechanisms (Fig. 2). Moreover, the  $\text{MoSe}_2$  interlayer has unique anisotropic structural properties. For example, the  $(00l)$  plane of  $\text{MoSe}_2$  has no surface dangling bond, making the nucleation process difficult while facilitating the diffusion and desorption of adatoms on the  $(00l)$  plane of  $\text{MoSe}_2$ . However, the nucleation process of  $\text{Sb}_2\text{Se}_3$  could be easily formed on a plane having a high-dangling bond density, such as the one perpendicular to the  $(00l)$  plane. Therefore, the  $\text{MoSe}_2$  interlayer was expected to provide a selective nucleation site, facilitating the formation of the  $\text{Sb}_2\text{Se}_3$  rod array on the  $\text{MoSe}_2$  interlayer. To investigate in

**Fig. 2** Schematic diagram of the selective nucleation and growth mechanism of  $\text{Sb}_2\text{Se}_3$  on the randomly grown  $\text{MoSe}_2$  interlayer; (a) low surface energy plane, (b) high surface energy plane, and (c) growth of  $\text{Sb}_2\text{Se}_3$  nanorods on  $\text{MoSe}_2$  interlayer.

detail the interface between  $\text{Sb}_2\text{Se}_3$  and  $\text{MoSe}_2$ , a high-angle annular detector dark-field scanning transmission electron microscopy (HAADF-STEM) image of the  $\text{Sb}_2\text{Se}_3/\text{MoSe}_2/\text{Mo}$  sample was observed (Fig. S3, ESI<sup>†</sup>). The  $\text{MoSe}_2$  showed a two-dimensional crystal structure with weak van der Waals bonding forces and without dangling bonds in the  $c$ -plane of  $\text{MoSe}_2$ . Overall, the layer structure was oriented perpendicular to the Mo substrate. Interestingly, in our case, the density of the  $\text{MoSe}_2$  interlayer bunch seemed relatively low. Thus, the orientation of the flexible bunch of the  $\text{MoSe}_2$  layer was not perfectly aligned. The exposed- $\text{MoSe}_2$  layer on the surface consisted of a  $c$ -plane without dangling bonds and another plane with dangling bonds.

To confirm the effect of the substrate type on the morphology of the co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films, we also deposited  $\text{Sb}_2\text{Se}_3$  thin films on indium tin oxide (ITO) substrates using the same co-evaporation process. Unlike Mo substrates, all the co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on ITO substrates showed a similar dense thin-film morphology, regardless of the source evaporation rate (Fig. S1, ESI<sup>†</sup>) and substrate temperature (Fig. S2, ESI<sup>†</sup>). These results show that the type of substrate had a significant effect on the formation of  $\text{Sb}_2\text{Se}_3$  nanorods by the co-evaporation process.

To evaluate the photovoltaic characteristics of the co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on different Mo and  $\text{MoSe}_2/\text{Mo}$  substrates, three different  $\text{Sb}_2\text{Se}_3$  solar cells with a planar device structure of  $\text{SLG}/\text{Mo}/\text{MoSe}_2/\text{Sb}_2\text{Se}_3/\text{CdS}/i\text{-ZnO}/\text{AZO}/\text{Al}$  were fabricated. Fig. 3 shows the cross-sectional TEM and energy dispersive X-ray spectroscopy (EDS) mapping images of the  $\text{Sb}_2\text{Se}_3$  solar cells fabricated at different source evaporation rates and with different substrates. The  $\text{Sb}_2\text{Se}_3$  solar cells without the  $\text{MoSe}_2$  interlayer showed a planar structure (Fig. 3a and b), due to the flat  $\text{Sb}_2\text{Se}_3$  thin-film structure shown in Fig. 1c. The CdS buffer,  $i$ -ZnO window, and AZO TCO layers were uniformly deposited on the flat  $\text{Sb}_2\text{Se}_3$  absorber layer. However, the  $\text{Sb}_2\text{Se}_3$  solar cells prepared on  $\text{MoSe}_2/\text{Mo}$  substrates showed completely different nanostructures than those using the Mo substrate. The  $\text{Sb}_2\text{Se}_3$  absorber layer showed a complex nanorod array, and the CdS buffer layer was deposited on the  $\text{Sb}_2\text{Se}_3$  nanorods conformally. The ZnO and AZO layers deposited on the rough CdS/ $\text{Sb}_2\text{Se}_3$  interface showed irregular nanostructures. At the bottom of the  $\text{Sb}_2\text{Se}_3$  absorber layer, a uniformly formed  $\text{MoSe}_2$  interlayer was confirmed. Moreover, the source evaporation rate showed a considerable effect on the nanostructure of the  $\text{Sb}_2\text{Se}_3$  absorber layer. The  $\text{Sb}_2\text{Se}_3$  solar cells prepared using a  $200 \text{ \AA s}^{-1}$  source evaporation rate on  $\text{MoSe}_2/\text{Mo}$  substrates showed an irregular and agglomerated  $\text{Sb}_2\text{Se}_3$  grain structure (Fig. 3c and d). However, when the evaporation rate decreased to  $100 \text{ \AA s}^{-1}$ , the  $\text{Sb}_2\text{Se}_3$  absorber layer showed a more ordered and regular nanorod array (Fig. 3e and f). These different  $\text{Sb}_2\text{Se}_3$  nanorod array structures observed according to the source evaporation rate were consistent with the SEM images (Fig. 1e and f).

Table 1 lists the photovoltaic properties of the  $\text{Sb}_2\text{Se}_3$  solar cells with and without the  $\text{MoSe}_2$  interlayer. Despite the planar and uniform device structure of the  $\text{Sb}_2\text{Se}_3$  solar cells without

Fig. 3 Cross-sectional TEM and EDS mapping images of  $\text{Sb}_2\text{Se}_3$  solar cells fabricated with different source evaporation rates and at a temperature of  $290 \text{ }^\circ\text{C}$ . (a) and (b),  $200 \text{ \AA s}^{-1}$  on a Mo substrate; (c) and (d),  $200 \text{ \AA s}^{-1}$  on a  $\text{MoSe}_2/\text{Mo}$  substrate; and (e) and (f)  $100 \text{ \AA s}^{-1}$  on a  $\text{MoSe}_2/\text{Mo}$  substrate.

the  $\text{MoSe}_2$  interlayer, the solar cells with the  $\text{MoSe}_2$  interlayer showed a superior photovoltaic performance. The higher open-circuit voltage ( $V_{\text{OC}}$ ) showed by the  $\text{Sb}_2\text{Se}_3$  solar cells with the  $\text{MoSe}_2$  interlayer might be attributed to the quasi-ohmic contact formation between  $\text{Sb}_2\text{Se}_3$  and  $\text{MoSe}_2$ . The quasi-ohmic contact formation of the  $\text{MoSe}_2$  interlayer is well known for copper indium gallium diselenide (CIGS) solar cells.<sup>27–31</sup> This quasi-ohmic contact could reduce the contact barrier and series resistance of  $\text{Sb}_2\text{Se}_3$  solar cell devices. The higher  $J_{\text{SC}}$  could be related to the 3D p–n junction formation between the  $\text{Sb}_2\text{Se}_3$  absorber and CdS buffer layers. Due to the 3D p–n junction structure, photo-generated carriers can easily escape into the CdS buffer layer. Thus, nanostructured  $\text{Sb}_2\text{Se}_3$  solar cells show a higher  $J_{\text{SC}}$  than flat thin-film  $\text{Sb}_2\text{Se}_3$  solar cells. This superior photovoltaic performance was consistent with the results reported by Park *et al.* and was also attributed to the 3D p–n junction formation between the  $\text{Sb}_2\text{Se}_3$  and CdS buffer layers.<sup>17</sup> Between the two  $\text{Sb}_2\text{Se}_3$  solar cells with a  $\text{MoSe}_2$  interlayer, the one fabricated at an evaporation rate of  $100 \text{ \AA s}^{-1}$  showed higher  $J_{\text{SC}}$  and fill factor (FF) than that at  $200 \text{ \AA s}^{-1}$ , which might be attributed to the more regular and ordered 3D p–n junction formation between  $\text{Sb}_2\text{Se}_3$  and CdS.

A previous report showed that high substrate temperatures induce the evolution of  $\text{Sb}_2\text{Se}_3$  nanorod arrays, demonstrating the close relationship between the nanostructure of

**Table 1** Photovoltaic characteristics of the  $\text{Sb}_2\text{Se}_3$  solar cells using  $\text{MoSe}_2/\text{Mo}$  substrates at 290 °C. Open-circuit voltage ( $V_{\text{OC}}$ ), short-circuit current ( $J_{\text{SC}}$ ), fill factor (FF), power conversion efficiency (PCE), and series and shunt resistances ( $R_s$ ,  $R_{\text{sh}}$ )

Substrate	Evaporation rate [ $\text{\AA} \text{s}^{-1}$ ]	$V_{\text{OC}}$ [V]	$J_{\text{SC}}$ [ $\text{mA cm}^{-2}$ ]	FF [%]	Eff [%]	$R_s$ [ $\Omega \text{cm}^2$ ]	$R_{\text{sh}}$ [ $\Omega \text{cm}^2$ ]
Mo	200	0.20297	8.4189	27.2369	0.465	18.105	26.703
$\text{MoSe}_2/\text{Mo}$	200	0.43951	21.1832	36.0716	3.358	9.847	51.383

co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films and substrate temperature.<sup>17</sup> Therefore, we have tried to tune the nanostructure of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films by controlling the substrate temperature at a source evaporation rate of  $100 \text{\AA} \text{s}^{-1}$  on  $\text{MoSe}_2/\text{Mo}$  substrates. We also prepared co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on bare Mo at 315 °C, which is the requirement for  $\text{Sb}_2\text{Se}_3$  nanorod array formation on bare Mo substrates. Fig. 4 shows

the top and cross-sectional SEM images of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films at different substrate temperatures on bare Mo or  $\text{MoSe}_2/\text{Mo}$ .

The co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on the  $\text{MoSe}_2/\text{Mo}$  substrate did not show the abrupt morphology change, from the flat thin-film structure to a nanorod array, observed in our previous report on Mo substrates.<sup>17</sup> Because the  $\text{MoSe}_2$  interlayer already easily induces the formation of the  $\text{Sb}_2\text{Se}_3$  nanorod array, the substrate temperature showed little effect on the formation of the  $\text{Sb}_2\text{Se}_3$  nanorod array. However, the detailed nanostructure of the  $\text{Sb}_2\text{Se}_3$  nanorods was affected by the substrate temperature. As the substrate temperature decreased from 290 to 250 °C, the shape regularity and the degree of ordering of the  $\text{Sb}_2\text{Se}_3$  nanorods improved. As the substrate temperature decreases, the  $\text{Sb}_2\text{Se}_3$  nuclei density increases, suppressing the rapid growth of  $\text{Sb}_2\text{Se}_3$  nanorods. Therefore, the growth of  $\text{Sb}_2\text{Se}_3$  nanorods could be controlled effectively to form an ordered  $\text{Sb}_2\text{Se}_3$  nanorod array by adjusting the substrate temperature on  $\text{MoSe}_2/\text{Mo}$ . Moreover, using the  $\text{MoSe}_2$  interlayer, it was possible to control the nanostructure of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films by varying both the evaporation rate and substrate temperature. Co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on a bare Mo substrate at 315 °C also showed a similar  $\text{Sb}_2\text{Se}_3$  nanorod structure to that on  $\text{MoSe}_2/\text{Mo}$  substrates, which is consistent with the results from our previous work.<sup>17</sup> The bare Mo substrate required a higher substrate temperature to form a similar  $\text{Sb}_2\text{Se}_3$  nanorod array to the one obtained using  $\text{MoSe}_2/\text{Mo}$  substrates and the co-evaporation process.

The crystalline orientation of  $\text{Sb}_2\text{Se}_3$  thin films is well known to be crucial for determining the photovoltaic properties of  $\text{Sb}_2\text{Se}_3$  solar cells due to the intrinsic one-dimensional ribbon structure of  $\text{Sb}_2\text{Se}_3$ .<sup>32–34</sup> Therefore, the crystalline structure of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on  $\text{MoSe}_2/\text{Mo}$  substrate at different substrate temperatures was analyzed by XRD analysis. All the co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films showed characteristic XRD peaks of  $\text{Sb}_2\text{Se}_3$ . However, the relative intensity of specific peaks corresponding to different crystalline orientations was different for each substrate temperature. Particularly, at 260 °C where the (020) and (120) peaks were not observed, and the intensity of the (211) and (221) peaks increased (Fig. 5a). To further investigate the crystalline orientation of the co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films, their texture coefficient was calculated.<sup>35–37</sup> At 260 °C the texture coefficient of the (211) peak was remarkably higher than that at other substrate temperatures (Fig. 5b). Additionally, all other  $\text{Sb}_2\text{Se}_3$  thin films showed relatively higher texture coefficients of ( $hk0$ ) than those at 260 °C. The ( $hk1$ ) preferential orientation of the  $\text{Sb}_2\text{Se}_3$  thin

**Fig. 4** Top and cross-sectional SEM images of  $\text{Sb}_2\text{Se}_3$  thin films at a source evaporation rate of  $100 \text{\AA} \text{s}^{-1}$  and different deposition temperatures: (a), 250; (b), 260; (c), 270; and (d), 290 °C using  $\text{MoSe}_2/\text{Mo}$  substrates; and (e), 315 °C using a bare Mo substrate.

Fig. 5 XRD peaks (a) and texture coefficient (b) of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films at different substrate temperatures and at a source evaporation rate of  $100 \text{ \AA s}^{-1}$ .

film at a substrate temperature of  $260 \text{ }^\circ\text{C}$  could help in improving the photovoltaic performance of  $\text{Sb}_2\text{Se}_3$  solar cells.

$\text{Sb}_2\text{Se}_3$  solar cells were fabricated at different substrate temperatures to investigate the effect of substrate temperature of co-evaporated  $\text{Sb}_2\text{Se}_3$  thin films on their photovoltaic performance. Fig. 6 shows the  $I$ - $V$  curves of the  $\text{Sb}_2\text{Se}_3$  solar cells at a source evaporation rate of  $100 \text{ \AA s}^{-1}$  and different substrate temperatures, and Table 2 lists the photovoltaic properties obtained for the  $\text{Sb}_2\text{Se}_3$  solar cells. All the  $\text{Sb}_2\text{Se}_3$  solar cells using the  $\text{MoSe}_2$  interlayer showed a  $V_{\text{OC}} > 0.4 \text{ V}$ , regardless of the substrate temperature. Because the  $\text{MoSe}_2$  interlayer already improved the  $V_{\text{OC}}$ , the structural change in the  $\text{Sb}_2\text{Se}_3$  nanorods had little effect on the  $V_{\text{OC}}$ . The  $\text{Sb}_2\text{Se}_3$  solar cell using a bare Mo substrate showed a slightly lower  $V_{\text{OC}}$  ( $0.37 \text{ V}$ ) than that with  $\text{MoSe}_2/\text{Mo}$  substrates. These results show that the introduction of the  $\text{MoSe}_2$  interlayer significantly improves the  $V_{\text{OC}}$  of  $\text{Sb}_2\text{Se}_3$  solar cells. The  $\text{Sb}_2\text{Se}_3$  solar cell prepared at a substrate temperature of  $260 \text{ }^\circ\text{C}$  showed the highest  $J_{\text{SC}}$ . This might be attributed to the  $(hk1)$  preferential orientation of the  $\text{Sb}_2\text{Se}_3$  absorber layer. Moreover, the ordered and regular  $\text{Sb}_2\text{Se}_3$  nanorod array could help increase the area of the 3D p-n junction between  $\text{Sb}_2\text{Se}_3$  and CdS, improving the  $J_{\text{SC}}$  of the  $\text{Sb}_2\text{Se}_3$  solar cells. By the way, it showed comparable  $J_{\text{SC}}$  ( $25.138 \text{ mA cm}^{-2}$ ) to those of the  $\text{Sb}_2\text{Se}_3$  solar cell with  $\text{MoSe}_2/\text{Mo}$  substrates because of the densely packed  $\text{Sb}_2\text{Se}_3$  nanorod array. Interestingly,  $\text{Sb}_2\text{Se}_3$  solar cells using a

Table 2 Photovoltaic characteristics of the  $\text{Sb}_2\text{Se}_3$  solar cells using  $\text{MoSe}_2/\text{Mo}$  and bare Mo substrates at different temperatures ( $T$ ). Open-circuit voltage ( $V_{\text{OC}}$ ), short-circuit current ( $J_{\text{SC}}$ ), fill factor (FF), power conversion efficiency (PCE), and series and shunt resistances ( $R_s$ ,  $R_{\text{sh}}$ )

Substrate	Temperature [ $^\circ\text{C}$ ]	$V_{\text{OC}}$ [V]	$J_{\text{SC}}$ [ $\text{mA cm}^{-2}$ ]	FF [%]	Ef f[%]	$R_s$ [ $\Omega \text{ cm}^2$ ]	$R_{\text{sh}}$ [ $\Omega \text{ cm}^2$ ]
$\text{MoSe}_2$	250	0.40	22.167	43.99	3.886	5.48	67.59
$\text{MoSe}_2$	260	0.43	27.430	47.35	5.637	5.89	118.26
$\text{MoSe}_2$	270	0.42	23.834	44.47	4.464	6.04	80.89
$\text{MoSe}_2$	290	0.45	23.661	40.27	4.288	8.49	70.32
Mo	315	0.37	25.138	47.11	4.412	5.69	112.25

$\text{MoSe}_2/\text{Mo}$  substrate at  $250$ ,  $270$  and  $290 \text{ }^\circ\text{C}$  showed a relatively smaller  $J_{\text{SC}}$  than bare Mo substrate. The nanostructure changes of the co-evaporated  $\text{Sb}_2\text{Se}_3$  nanorod array by temperature is remarkable (Fig. 4), which might be closely related to the  $J_{\text{SC}}$  and FF of  $\text{Sb}_2\text{Se}_3$  solar cells. At  $250 \text{ }^\circ\text{C}$ , the width of  $\text{Sb}_2\text{Se}_3$  nanorods is smaller than that at  $260 \text{ }^\circ\text{C}$ , which is disadvantageous for sufficient light absorption. The length uniformity of  $\text{Sb}_2\text{Se}_3$  nanorods at  $270$  and  $290 \text{ }^\circ\text{C}$  is inferior compared to that at  $260 \text{ }^\circ\text{C}$ . The irregular nanostructure of the  $\text{Sb}_2\text{Se}_3$  nanorods induces insufficient light absorption and photo-generated carrier transportation. The thinner rods ( $250 \text{ }^\circ\text{C}$ ) and increased empty space ( $270 \text{ }^\circ\text{C}$ ) could deteriorate the FF by increasing the shunt paths too.

To investigate the correlation between the 3D p-n junction structure and the photovoltaic properties of  $\text{Sb}_2\text{Se}_3$  solar cells, TEM analysis of the best  $\text{Sb}_2\text{Se}_3$  solar cell, with the evaporation rate of  $100 \text{ \AA s}^{-1}$  and the substrate temperature of  $260 \text{ }^\circ\text{C}$ , was performed. Fig. 7 shows the TEM-EDS mapping images of the  $\text{Sb}_2\text{Se}_3$  solar cell device with a nanorod array with a PCE of  $5.637\%$  (Table 2). The  $\text{Sb}_2\text{Se}_3$  solar cell using a  $\text{MoSe}_2/\text{Mo}$  substrate showed a  $1.225\%$  higher PCE than the one using a bare Mo substrate, which might be attributed to the improved  $V_{\text{OC}}$ . A densely packed, uniformly distributed,  $\text{Sb}_2\text{Se}_3$  nanorod array and the 3D p-n junction between CdS and  $\text{Sb}_2\text{Se}_3$  nanorods were observed. These properties are advantageous for the enhancement of  $J_{\text{SC}}$ . Additionally, the uniform  $\text{MoSe}_2$  interlayer between the Mo substrate and the  $\text{Sb}_2\text{Se}_3$  nanorod array is beneficial for the formation of a quasi-ohmic contact between the layers.

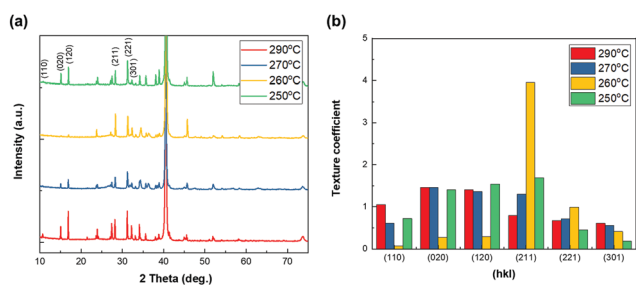

Fig. 6  $I$ - $V$  curves of  $\text{Sb}_2\text{Se}_3$  solar cells at a source evaporation rate of  $100 \text{ \AA s}^{-1}$  and different substrate temperatures: (a),  $250$ ; (b),  $260$ ; (c),  $270$ ; and (d),  $290 \text{ }^\circ\text{C}$  using  $\text{MoSe}_2/\text{Mo}$  and bare Mo substrates.

Fig. 7 STEM-EDS mapping images of  $\text{Sb}_2\text{Se}_3$  nanorod array solar cell with PCE of  $5.637\%$ .

Fig. 8 Certified  $J$ - $V$  curve (a) and external quantum efficiency (EQE) data (b) of  $\text{Sb}_2\text{Se}_3$  solar cells at a substrate temperature of  $260^\circ\text{C}$  and a source evaporation rate of  $100 \text{ \AA s}^{-1}$  using a  $\text{MoSe}_2/\text{Mo}$  substrate (Korea Institute of Energy Research, KIER).

The results presented in this work reveal that the  $\text{MoSe}_2$  interlayer between a Mo substrate and a  $\text{Sb}_2\text{Se}_3$  absorber layer improves the performance of  $\text{Sb}_2\text{Se}_3$  solar cells in two relevant ways. First, the contact quality between  $\text{Sb}_2\text{Se}_3$  and Mo layers improved due to quasi-ohmic contact formation, which was confirmed by the higher  $V_{\text{OC}}$  values of  $\text{Sb}_2\text{Se}_3$  solar cells using  $\text{MoSe}_2/\text{Mo}$  substrates compared to those using a bare Mo substrate; second, a facile formation of the  $\text{Sb}_2\text{Se}_3$  nanorod array and a lower substrate temperature were achieved using the co-evaporation process, which was followed by the 3D p-n junction  $\text{Sb}_2\text{Se}_3$  solar cell fabrication. Moreover, the  $\text{MoSe}_2$  interlayer played a key role in improving the photovoltaic performance of the  $\text{Sb}_2\text{Se}_3$  nanorod array solar cell by increasing both  $V_{\text{OC}}$  and  $J_{\text{SC}}$ . The quasi-ohmic contact caused by the  $\text{MoSe}_2$  interlayer effectively improved the contact quality between  $\text{Sb}_2\text{Se}_3$  layers and Mo substrates. Moreover, the  $\text{MoSe}_2$  interlayer also played a critical role as a seed layer for the uniform growth of the  $\text{Sb}_2\text{Se}_3$  nanorod array.

The  $\text{Sb}_2\text{Se}_3$  solar cells prepared by co-evaporation at a source evaporation rate of  $100 \text{ \AA s}^{-1}$  and substrate temperature of  $260^\circ\text{C}$  on a  $\text{MoSe}_2/\text{Mo}$  substrate were analyzed by an external certified laboratory to verify our PCE laboratory measurements. The certified  $J$ - $V$  curve (Fig. 8a) and external quantum efficiency data (Fig. 8b) showed similar results (PCE of 5.484%) to our lab-scale photovoltaic measurements. We calculated integrated  $J_{\text{SC}}$  from EQE data and compared with the  $J_{\text{SC}}$  of  $J$ - $V$  curve. The  $J_{\text{SC}}$  from integrated EQE ( $25.89 \text{ mA cm}^{-2}$ ) is similar to the  $J_{\text{SC}}$  of the  $J$ - $V$  curve ( $26.05 \text{ mA cm}^{-2}$ ).

## Conclusions

This work investigated the role of the  $\text{MoSe}_2$  interlayer on the growth of the  $\text{Sb}_2\text{Se}_3$  nanorod array and the contact quality between  $\text{Sb}_2\text{Se}_3$  thin films and Mo substrates. By introducing a  $\text{MoSe}_2$  interlayer between  $\text{Sb}_2\text{Se}_3$  layers and Mo substrates, uniformly ordered densely packed  $\text{Sb}_2\text{Se}_3$  nanorods were successfully prepared. The  $\text{MoSe}_2$  interlayer, with locally distributed high surface energy planes, played a crucial role as a seed layer for the preferential growth of  $\text{Sb}_2\text{Se}_3$  crystals perpendicular to the substrate, which facilitated the formation of a  $\text{Sb}_2\text{Se}_3$  nanorod array on the  $\text{MoSe}_2$  interlayer. The latter also significantly improved the photovoltaic performance of  $\text{Sb}_2\text{Se}_3$

solar cell devices by forming a quasi-ohmic contact between  $\text{Sb}_2\text{Se}_3$  absorber layers and Mo substrates, resulting in higher  $V_{\text{OC}}$  and  $J_{\text{SC}}$ . The nanostructure and crystalline orientation of the  $\text{Sb}_2\text{Se}_3$  nanorods array were affected by the substrate temperature and the source evaporation rate during the co-evaporation process. 3D p-n junction solar cells based on an ordered and ( $hk1$ ) preferentially oriented  $\text{Sb}_2\text{Se}_3$  nanorods array showed a PCE of 5.637%.
