Layered hybrid perovskites are based on organic spacers separating hybrid perovskite slabs. We employ arene and perfluoroarene moieties based on 1,4-phenylenedimethylammonium (PDMA) and its perfluorinated analogue (F-PDMA) in the assembly of hybrid layered Dion–Jacobson perovskite phases. The resulting materials are investigated by X-ray diffraction, UV-vis absorption, photoluminescence, and solid-state NMR spectroscopy to demonstrate the formation of layered perovskite phases. Moreover, their behaviour was probed in humid environments to reveal nanoscale segregation of layered perovskite species based on PDMA and F-PDMA components, along with enhanced stabilities of perfluoroarene systems, which is relevant to their application.

Introduction

Layered hybrid perovskites (or 2D perovskites) are derived from three-dimensional organic–inorganic perovskites of general formula AMX₃ (Fig. 1a).¹⁻³ Here, A is the central cation (e.g. methylammonium MA⁺, formamidinium FA⁺, or Cs¹), M a divalent metal ion (mostly Pb²⁺ or Sn²⁺) and X a halide anion (I⁻,Br⁻, or Cl⁻).⁴⁻⁵ The incorporation of a larger spacer cation between hybrid perovskite slabs can lead to the formation of 2D perovskite architectures, which have attracted attention due to their enhanced stabilities and versatility as compared to their 3D counterparts (Fig. 1b and c).⁶⁻⁸ In particular, two classes of 2D perovskite materials are of special interest, namely the Ruddlesden–Popper (RP) and Dion–Jacobson (DJ) phases.⁹⁻¹⁴ RP systems mostly follow the general formula S₂Aₓ₋₁MₓX₃ₓ₋₁, where S are monofunctional spacers that interact with the perovskite slabs by forming a bilayer with a half-unit-cell displacement between the perovskite slabs (Fig. 1b).⁷,¹⁵ On the contrary, DJ systems are commonly based on the general formula SAₓ₋₁MₓX₃ₓ₋₁ incorporating bifunctional spacer (S) moieties between aligned perovskite slabs (Fig. 1c).¹⁶ While RP phases have been widely used in perovskite.
kite optoelectronics, DJ phases are underrepresented despite their appealing optoelectronic properties and environmental stability.\textsuperscript{17–20} It is thereby of interest to understand and control their structural and optoelectronic properties, which are highly dependent on the supramolecular self-assembly of the organic spacer layer.

A complementary pair of organic spacers could engage in π–π interactions, e.g. between arene and perfluoroarene species, through self-assembly to form an alternating-cation 2D perovskite system.\textsuperscript{21} This has been previously analysed based on 2-phenylethylammonium (PEA) and 2-(perfluorophenyl)ethylammonium (FEA), forming an RP phase.\textsuperscript{21} Such a favourable interaction is based on the complementarity between the quadrupole moments of the aromatic rings that is expected to yield a more compact parallel (π–π) stacking in arene-perfluoroarene systems (Fig. 1d).\textsuperscript{21–26} This could alter the optoelectronic properties of the hybrid material.\textsuperscript{14,16,27–29} In addition, the fluoroarene moieties are expected to increase hydrophobicity and reduce halide ion migration through π-ion interactions, which is relevant for the stability of the resulting materials.\textsuperscript{24,26,30–32} Such tailored arene-perfluoroarene π-interactions, however, remain unexploited in controlling the properties of DJ perovskite phases.\textsuperscript{16,21,26,33}

Here, we investigate a DJ system employing arene and perfluoroarene species, namely 1,4-phenylenedimethylammonium (PDMA) and its analogue comprising a perfluorinated phenylene moiety (F-PDMA), as well as their mixture (1:1 PDMA:F-PDMA, denoted as PF) by solution-processing followed by annealing, in accordance with the procedure reported in the ESL.\textsuperscript{†}

Structural properties were investigated by X-ray diffraction (XRD) in the Bragg–Brentano configuration (Fig. 2). The XRD patterns of the thin films show low angle reflections (<10°) at 2θ of 7.22°, 6.93° and 7.17° for (PDMA)PbI\textsubscript{4}, (F-PDMA)PbI\textsubscript{4} and (PF)PbI\textsubscript{4}, respectively, which is accompanied by periodic patterns typical of layered (2D) perovskite structures.\textsuperscript{27,29,34,35} This is particularly the case for (PDMA)PbI\textsubscript{4} (Fig. 2a), whereas (F-PDMA)PbI\textsubscript{4} shows lower intensity peaks with a poor signal-to-noise ratio, suggesting lower crystallinity (Fig. 2b). We further observed a low angle diffraction for the mixed (PF)PbI\textsubscript{4} system characteristic for 2D structures, with an increase in relative intensity of the 14° and 28° diffraction peaks (Fig. 2c). This suggests that the presence of F-PDMA modifies out-of-plane texture of the films. To corroborate this, we analysed the films by grazing incidence wide angle X-ray scattering (GIWAXS) measurements (Fig. 2d–f and Fig. S4, ESI\textsuperscript{†}). Films with different (5%, 10%, 25% and 50%) F-PDMA content were investigated (denoted as 5%, 10%, 25%, and 50% (PF), respectiv...
PF-based compositions, which is likely a consequence of competing fluorine-based interactions in PF-based systems, in accordance with previous reports.26,33

The atomic-level interactions were further analysed by solid-state nuclear magnetic resonance (NMR) spectroscopy (Fig. 3).14 Solid-state NMR has emerged as a powerful method to characterize the atomic-level structure of lead-halide perovskite materials.36–42 To shed light on the coordination and distribution of the spacer ligands within the DJ phases, we relied on our previously developed approach.21 Specifically, $^{19}$F NMR spectra were recorded for the fluorinated spacer (F-PDMA) and a mechanosynthetic mixture of the two spacers (F-PDMA and PDMAI2 stoichiometric 1 : 1 mixture, denoted as PF (Fig. 3a)), as well as their corresponding 2D perovskites, namely (F-PDMA)PbI4 and (PF)PbI4 (Fig. 3b). The $^{19}$F NMR spectra of the F-PDMA spacer in pure state and within a mixture with PDMA were found to be identical, featuring two fluorine signals at $–135$ and $–139$ ppm, indicating that the chemical surrounding of the fluorine atoms is the same in both samples. This suggests that the PDMAI2 and F-PDMAI2 powders do not form a homogeneous phase upon mixing, but remain spatially separated within microcrystalline grains constituted of only one of the two molecules. However, the $^{19}$F NMR spectra of 2D perovskites substantially change as compared to the spectrum of the pristine spacer, with different intensity ratios of the $^{19}$F NMR signals, indicating the formation of new phases. This evidences that the fluorine atoms experience a different chemical surrounding within the perovskite material, in agreement with the incorporation of F-PDMA into the perovskite structure.

Similarly, $^{19}$F NMR of a 2D perovskite phase based on a 1 : 1 spacer mixtures (PF) reveals the formation of a different phase as it exhibits an additional signal at ca. $–130$ ppm, whereas the other two signals remain almost unchanged in intensity and chemical shift. This is in accordance with nanosegregation into domains within the 2D perovskite material in which all spacers are fluorinated, forming the same phase as in materials prepared exclusively from F-PDMA. The additional signal at $–130$ ppm could either originate from the fluorinated spacers at the interface of these domains or from the domains where F-PDMA and PDMA form a homogeneous mixture. We have investigated this further by comparing $^{13}$C cross-polarisation (CP) NMR spectra obtained by transferring polarisation either from $^1$H or from $^{19}$F nuclei (Fig. 3c and detailed in the ESI†). While the resolution of the $^{19}$F $\rightarrow$ $^{13}$C CP NMR spectra was insufficient to extract any additional structural insight, $^1$H $\rightarrow$ $^{13}$C CP NMR corroborates the co-existence of independent phases, each comprising only one spacer, in the mixed system, further evidencing their nanosegregation. In summary, solid-state NMR further confirms that F-PDMA is integrated into the DJ 2D perovskite structure, while evidencing that the mixture of spacers (F-PDMA and PDMA) leads to phase segregation, which is in accordance with a previous report on perfluorinated spacers in RP phases.21 These structural changes are directly reflected in the optoelectronic properties of the films.

The optical properties of the thin films were analysed by UV-vis absorption and PL spectroscopy. The excitonic features in the absorption spectrum in the range of 490–500 nm are in agreement with the formation of layered 2D structures.9,20,14 For (PDMA)PbI4, (F-PDMA)PbI4 and (PF)PbI4, absorption maxima were observed at 510 nm, 480 nm, and 505 nm, respectively (Fig. 4a). Thin films containing mixtures of arene and perfluoroarene spacers with increasing amounts of F-PDMA (5%, 10%, and 25%) feature a gradual blue shift of the absorption maximum to 510 nm, 509 nm, and 507 nm, respectively (Fig. S5, ESI†). Similarly, PL spectra (Fig. 4b and
show minor Stokes shifts of ca. 20 nm, 10 nm, and 15 nm for (PDMA)PbI\(_4\), (F-PDMA)PbI\(_4\) and (PF)PbI\(_4\), respectively, accompanied by a gradual reduction in photo-luminescence quantum yield (PLQY) related to their excitonic characteristics (Fig. S6, ESI†), confirming that the presence of F-PDMA has an impact on the optical properties. The corresponding PL spectra of neat F-PDMA-based thin films also appear to involve multiple signals, which is likely associated with their structural disorder and requires further investigation.

Having evidenced the 2D perovskite formation through optical and structural properties, the stability of the materials was analysed by monitoring the behaviour of the films in humid environments.\(^3^4,4^3\) For this purpose, we measured contact angles (Fig. S7, ESI†) for the films based on F-PDMA, PDMA and with various amounts of F-PDMA (5%, 10%, 25% and 50% (PF)) with respect to PDMA in 2D perovskite compositions. With increasing F-PDMA content from 0%, over 5%, 10%, 25%, up to 50%, contact angles of 49.6°, 59.6°, 62.1°, 63.3°, and 60.1° were obtained, respectively, showing a substantial increase in hydrophobicity in the presence of F-PDMA. The system based on 25% F-PDMA demonstrated the greatest hydrophobicity, which was accompanied by the highest intensity of diffraction peaks that are commonly associated with the crystallites of perovskite layers that are perpendicular to the substrate (Fig. S5, ESI†).\(^3^4\) This suggests that the changes in hydrophobicity are likely not only associated with the fluoroarene content but also with the orientation of crystallites and the organic spacers in the films. The environmental stability was further assessed by measuring optical (UV-vis absorption and PL spectra) as well as structural properties (XRD) after exposing the samples to a relative humidity of 80 ± 5% for 15 min. While (PDMA)PbI\(_4\) is known to hydrate in humid conditions (Fig. 5a), \(^9,3^4,4^4\) (F-PDMA)PbI\(_4\) did not undergo any change (Fig. 5b). However, the UV-vis absorption spectra of mixed (PF)PbI\(_4\) films changed when exposed to humid conditions (Fig. 5c), with a 25 nm blue shift of the absorption peak at 510 nm and an increase of absorbance in the 405 nm region. Furthermore, recorded XRD patterns (Fig. 5d) reveal a transformation that could be depicted as a superimposition of the patterns of two species, i.e. the hydrated PDMA-based phase and the co-existing (F-PDMA)PbI\(_4\) phase.

This observation is in accordance with the formation of a segregated structure of the perovskite phases based on two spacer moieties in mixed thin films (Fig. 5e), as indicated by solid-state NMR spectroscopy. Since PDMAI-based films are known to hydrate, whereas F-PDMAI-based ones are resistant to hydration, the mixed cation system is expected to be more resilient to moisture. Instead, the formation of a hydrated PDMA phase suggests that, in contrast to the previous reports on arene-fluoroarene-based systems,\(^3^0,4^5\) the corresponding DJ systems remain nanosegregated. This process has been previously associated with improvements in photovoltaic performances and operational stabilities,\(^2^1\) which is relevant for the application of these materials in the future.

Conclusions

In summary, we investigated arene and perfluoroarene spacers, namely 1,4-phenylenedimethylammonium (PDMA) and its analogue containing a perfluorinated moiety (F-PDMA), for their propensity to form hybrid Dion–Jacobson layered perovskite materials through self-assembly. The analysis showed that PDMAI, F-PDMA, and their 1 : 1 mixture form...
layered perovskite materials, which are not well oriented in the case of F-PDMA-based films. Moreover, while the F-PDMA-based system showed resilience to moisture, its addition to the PDMA-based composition did not prevent hydration, suggesting the possible formation of a segregated structure which was confirmed by solid-state NMR spectroscopy. This provides insights for the design of Dion–Jacobson perovskites incorporating arene-perfluoroarene π-systems, stimulating further studies towards their application in optoelectronics.

Author contributions

The manuscript was written by M.A., J.V.M., A.D., L.P., and L.C.C. through support of all the co-authors. The study was conceptualized by J.V.M. who supervised L.C.C., M.A., E.L., W.L. and P.A.G. throughout the project. L.C.C. synthesized the organic spacer materials under the supervision of L.P., and he fabricated and characterized thin-films with the support of A.D., who also performed the mechanosynthesis of powders. W.L., E.L., and P.A.G. synthesized and characterized the organic spacer materials and the corresponding thin-films as well as mechanosynthesized powders to complement the investigation of their structural and optoelectronic properties, in particular by solid-state NMR spectroscopy, which was performed by L.Pi. S.M.Z. was involved in the discussions and the supervision of L.C.C. and M.A., while M.G. directed the project. All authors contributed to the writing process and approved the final version of the manuscript.
