# High performance and remarkable cyclic stability of a nanostructured RGO–CNT–WO<sub>3</sub> supercapacitor electrode

Farah Nasreen,<sup>a</sup> Abdul Waheed Anwar,<sup>b</sup>  <sup>✉</sup> Abdul Majeed,<sup>b</sup> Muhammad Ashfaq Ahmad,<sup>c</sup> Usman Ilyas<sup>a</sup> and Furqan Ahmad<sup>d</sup>

One of the most pressing concerns in today's power networks is ensuring that consumers (both home and industrial) have access to efficient and long-lasting economic energy. Due to improved power accessibility and high specific capacitance without deterioration over long working times, supercapacitor-based energy storage systems can be a viable solution to this problem. So, here, tungsten trioxide (WO<sub>3</sub>) nanocomposites containing reduced graphene oxide and carbon nanotubes *i.e.* (RGO–WO<sub>3</sub>), (CNT–WO<sub>3</sub>), and (RGO–CNT–WO<sub>3</sub>), as well as pure WO<sub>3</sub> nanostructures as electrode materials, were synthesized using a simple hydrothermal process. The monoclinic phase of WO<sub>3</sub> with high diffraction peaks is visible in X-ray diffraction analysis, indicating good crystallinity of all electrode materials. Nanoflowers of WO<sub>3</sub> were well-decorated on the RGO/CNTs conductive network in SEM micrographs. In a three-electrode system, the specific capacitance of the RGO–CNT–WO<sub>3</sub> electrode is 691.38 F g<sup>−1</sup> at 5 mV s<sup>−1</sup> and 633.3 F g<sup>−1</sup> at 2 A g<sup>−1</sup>, which is significantly higher than that of pure WO<sub>3</sub> and other binary electrodes. Furthermore, at 2 A g<sup>−1</sup>, it achieves a coulombic efficiency of 98.4%. After 5000 cycles, RGO–CNT–WO<sub>3</sub> retains 89.09% of its capacitance at 1000 mV s<sup>−1</sup>, indicating a promising rate capability and good cycling stability performance.

## 1. Introduction

The development of energy storage systems (ESSs) is crucial for tackling climate change and the finite availability of fossil fuels, as well as for storing solar and wind energy efficiently. One of the most difficult challenges now facing academics is to build highly efficient, low-cost, and environmentally friendly ESS devices. With the rapid rise of the portable electronic device industry and the development of hybrid electric vehicles, the demand for high-energy and high-power density energy storage technologies has surged. Even at increased power densities, the stored energy should be able to be released smoothly and distributed. Among these ESSs, supercapacitors are one of the most important technologies for energy storage applications because they can give better power and energy densities than batteries and ordinary dielectric capacitors.<sup>1–4</sup> A number of materials have already been studied as supercapacitor electrode materials. Amongst all, RuO<sub>2</sub> and IrO<sub>2</sub> are good supercapacitor electrode materials because they have a high specific

capacitance value and a high cycle capacity, which has sparked increased interest in this subject. However, their high cost and toxicity limit their practical application. One of the most active research subjects in electrochemistry is the creation of alternate economical and environmentally acceptable electrode materials with good performance. Many researchers are now working on alternate materials to IrO<sub>2</sub> and RuO<sub>2</sub>. One of the most enticing alternatives to RuO<sub>2</sub> and IrO<sub>2</sub> may be WO<sub>3</sub> owing to its electrochemical redox characteristics, environmental friendliness and low cost.<sup>5–7</sup> Tungsten trioxide (WO<sub>3</sub>) is a well-known wide band gap n-type semiconductor with a variety of unique features and many crystal forms that are suited for the intercalation of tiny cations such as H<sup>+</sup>. It's been explored extensively as a possible material for a variety of applications which includes solar energy devices, semiconductor gas sensors, photocatalysts, electrode materials for secondary batteries and supercapacitors, field-emission devices. As a supercapacitor electrode, the capacitive characteristics of tungsten oxides *e.g.* mesoporous tungsten oxide, nanostructured tungsten trioxide, amorphous tungsten oxide and others have been studied.<sup>8–11</sup> Xu He *et al.* developed and synthesized tungsten trioxide microspheres electrode materials with a specific capacitance of 488.78 F g<sup>−1</sup>.<sup>12</sup> M. Ashraf *et al.* presented an asymmetric supercapacitor (HRG/m-WO<sub>3</sub> ASC) made of monoclinic tungsten oxide (m-WO<sub>3</sub>) nanoplates for the negative electrode and highly reduced graphene oxide (HRG) for

the positive electrode and exhibited a specific capacitance of  $389 \text{ F g}^{-1}$  at a current density of  $0.5 \text{ A g}^{-1}$ .<sup>13</sup> Nevertheless, the main disadvantages of tungsten oxide pseudocapacitors are their limited electrical conductivity and weak rate performance. Supercapacitor resistance should be reduced to increase rate capability. However, tungsten oxide preparations with diverse morphologies have received a lot of attention in terms of capacitive characteristics. The majority of investigations, on the other hand, focused on  $\text{WO}_3$  nanostructures produced from nanostructures, nanorods, or films. Until now, the capacitive characteristics of  $\text{WO}_3$  and carbon composites have received little attention in research.<sup>14</sup> Concerning greater surface area, environmental friendliness, linked pore structure, high electrical conductivity and pore size regulation, carbon materials with varied micro textures are considered the major choice for supercapacitors.<sup>15–18</sup> When  $\text{WO}_3$  is mixed with carbon/graphene sheets that are extremely conductive, its conductivity greatly enhanced, resulting in good capacitive materials with excellent system conductivity. A 1D multi-walled CNTs (MWCNTs) and reduced graphene oxide interwoven network also enhance electrical conductivity while also providing greater electrochemically active surface area and efficient routes for both electrons and ions in a hybrid electrode.<sup>19</sup> The electrical double layer capacitor (EDLC) and pseudocapacitive processes in composites of  $\text{WO}_3$  and RGO/MWCNTs are of particular interest because they contain a dual charge storage mechanism.<sup>20</sup> In addition, chemical vapour deposition, sol-gel, hydrothermal technique, and other methods have been used to synthesize  $\text{WO}_3$  nanostructures in the current findings. Among these, the hydrothermal approach was deemed superior because it allows the preparation of  $\text{WO}_3$  nanoflowers in a mild, well-controlled, and cost-effective manner,<sup>21</sup> which was ideal for our experiment. In the present work, a facile hydrothermal procedure is demonstrated to prepare monoclinic tungsten trioxide combined with carbon nanotubes and reduced graphene oxide *i.e.* RGO-CNT- $\text{WO}_3$  composite electrode. The electrochemical experiments revealed that the RGO-CNT- $\text{WO}_3$  composite electrode has better capacitive properties than the  $\text{WO}_3$ , RGO- $\text{WO}_3$ , CNT- $\text{WO}_3$  electrode, with greater reversible charging/discharging capabilities and larger capacitance values along with high cyclic stability. The flower-like architectures of  $\text{WO}_3$  are very well assembled on reduced graphene sheets that are connected to CNTs with strong interfacial contact in RGO/CNT based tungsten trioxide nanocomposites, which ultimately provides the fastest electron transportation and thus enhances the performance of electrode.

## 2. Experimental section

The tungsten precursor was sodium tungstate dihydrate ( $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ ). The pH was adjusted with hydrochloric acid (HCl). DI water was used to dissolve the precursor, dilute the acid to the appropriate molarity, and wash the finished product. Ethanol was also used to remove any contaminants from the finished product. Nickel foam was employed as the substrate for slurry casting the as-prepared powder. The samples were slurry cast onto the substrate using PVDF, Nafion, and carbon black.

Sodium dodecyl benzenesulfonate (SDBS) was used to make CNTs solution in DI water. All of the reagents were acquired from Sigma Aldrich Co. LLC and utilized without additional purification. Nickel (Ni) foam was purchased from Winfay Group Co. Ltd, China.

### 2.1 Synthesis of $\text{WO}_3$ nanostructures

First of all, 2 g of  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$  was dissolved in 50 ml DI water followed by the addition of 3 M HCl (*i.e.* 12.5 ml HCl in 50 ml DI water) until the pH reached 1. After that, 3.06 g of oxalic acid and 4 g of  $(\text{NH}_4)_2\text{SO}_4$  were added. The mixture was transferred to a stainless steel autoclave lined with Teflon and holding 150 ml. The autoclave was sealed and placed in an oven at  $180^\circ\text{C}$  for 16 hours, after which it was allowed to cool naturally. The precipitate was filtered and washed with DI water and ethanol multiple times before being vacuum dried for 12 hours at  $80^\circ\text{C}$  (light grey colour Fig. 1a).

### 2.2 Synthesis of RGO- $\text{WO}_3$ nanostructures

To begin, a 40 ml (1 mg/1 ml) graphene oxide solution was prepared using sonication and centrifugation. The RGO- $\text{WO}_3$  nanocomposite was then made by dissolving 2 g of  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$  in 30 ml of deionized water and stirring it for 30 minutes with a magnetic stirrer. Then, drop by drop, 3 M HCl was added until the pH reached up to 1.3. 0.6 g of oxalic acid and  $(\text{NH}_4)_2\text{SO}_4$  were added after that. The solution was then diluted with 50 ml of deionized water. After that, the GO solution was gently added using sonication for 45 minutes. The solution was then put down into a Teflon-lined stainless steel autoclave and heated for 20 hours at  $180^\circ\text{C}$ . The RGO- $\text{WO}_3$  precipitate was filtered and washed multiple times with acetone and DI water and placed further in a vacuum oven to dry at  $80^\circ\text{C}$  for 12 h (Fig. 1b).

### 2.3 Synthesis of CNT- $\text{WO}_3$ nanostructures

First,  $10 \text{ mg ml}^{-1}$  MWCNTs were ultrasonically dispersed in  $5 \text{ mg ml}^{-1}$  sodium dodecyl benzenesulfonate (SDBS) for 8 hours. The CNT- $\text{WO}_3$  nanocomposite was then synthesized by dissolving 2 g of  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$  in 30 ml of deionized water and stirring it for 30 minutes with a magnetic stirrer. Then, drop by drop, 3 M HCl was added until the pH reached 1.3. 0.6 g of oxalic acid and 4 g of  $(\text{NH}_4)_2\text{SO}_4$  were added after that. The solution was then diluted with 50 ml of deionized water. After that, the CNT solution was gently added using sonication for 45 minutes. The solution was then put into a Teflon-lined stainless steel autoclave and heated for 20 hours at  $180^\circ\text{C}$ . The CNT- $\text{WO}_3$  precipitates were obtained through filtration and washing with

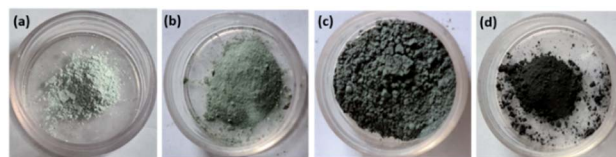

Fig. 1 Digital photographs of (a)  $\text{WO}_3$  (b) RGO- $\text{WO}_3$  (c) CNT- $\text{WO}_3$  (d) RGO-CNT- $\text{WO}_3$ .

Fig. 2 Schematic diagram of the synthesis of RGO-CNT-WO<sub>3</sub> through hydrothermal method.

acetone and DI water multiple times and placed further in a vacuum oven to dry at 80 °C for 12 h shown in Fig. 1c.

## 2.4 Synthesis of RGO-CNT-WO<sub>3</sub> nanostructures

By sonication for 9 hours, 10 mg ml<sup>-1</sup> MWCNTs were disseminated in 5 mg ml<sup>-1</sup> SDBS. Then, to make GO/CNT dispersion, 40 mg ml<sup>-1</sup> graphene oxide solution was mixed thoroughly with CNTs solution. The RGO-CNT-WO<sub>3</sub> nanocomposite was then synthesized by dissolving 2 g of Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O in 30 ml of deionized water and stirring it for 30 minutes with a magnetic stirrer. Then, drop by drop, 3 M HCl was added until the pH reached 1. Then, 3.06 g of oxalic acid and 4 g of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> were added after that. The solution was then diluted with 50 ml of deionized water. After that, the CNT solution was gently added using sonication for 45 minutes. The solution was then positioned into a Teflon-lined stainless steel autoclave and heated for 20 hours at 180 °C. RGO-CNT-WO<sub>3</sub> precipitates were obtained by filtration and washing with acetone and DI water multiple times before being dried for 12 hours in a vacuum oven at 80 °C. The final black product is exhibited in Fig. 1d. The Schematic diagram of the synthesis of RGO-CNT-WO<sub>3</sub> through hydrothermal method has been displayed in Fig. 2.

## 2.5 Structural characterization

The crystal structure was studied through X-ray diffraction (XRD; Rigaku Diffractometer) using Cu K $\alpha$  radiation with a wavelength of ( $\lambda = 1.5416 \text{ \AA}$ ) and a temperature range of 5° to 60°. Raman Spectroscopy (Jobin Yvon HR800) was also used to do the Raman analysis, which used a He-Ne laser with a wavelength of 632.8 nm. Scanning Electron Microscopy was employed to investigate the morphology of nanocomposites (Nova NanoSEM 430, 10 kV).

## 2.6 Electrochemical characterization and fabrication of electrodes

Under a three-electrode cell configuration in 3 M KOH at ambient temperature, cyclic voltammetry (CV), galvanostatic charge-discharge (GCD), electrochemical impedance spectroscopy (EIS), and cyclic stability tests of composite electrodes were investigated. As working, counter, and reference electrodes, the as-prepared composite electrodes, platinum wire, and Ag/AgCl were employed respectively. On an electrochemical workstation (Gamry Reference 3000 Instrument, USA), all electrochemical properties were recorded. To make the working

electrodes, the nickel sponge was cleaned with acetone, 2 M HCl, ethanol, and DI water many times for 15 minutes each. After that, it is dried entirely at 90 °C for 12 hours. The nickel sponge was sliced into (1 × 1 cm<sup>2</sup>) dimensions after drying. In NMP solution, the electrode active material, polyvinylidene fluoride (PVDF), and acetylene black were mixed in 80 : 10 : 10 ratio to produce a homogenous slurry. Finally, this paste was spread onto sponge to make composite electrodes, which were then dried for 8 hours at 90 °C. The difference between loaded and unloaded nickel foam was used to compute the loading density of active materials for composite electrodes. The loading density of active materials for all electrodes was 1 mg cm<sup>-2</sup>. Using an Ag/AgCl reference electrode, CV experiments were conducted in the 0–0.48 voltage range at 5, 10, 20, 40 and 50 mV s<sup>-1</sup>. GCD tests were performed at densities of 2, 4, 6, and 8 A g<sup>-1</sup>. EIS study was performed with a 10 mV AC voltage amplitude and a frequency range of 1 Hz to 10<sup>5</sup> Hz. Eqn (1) and (2) are used to calculate specific capacitance ( $C_s$ ) from CVs and galvanostatic discharging curves respectively;

$$C = \frac{1}{m\Delta V} \int i(V) dV \quad (1)$$

$$C = \frac{I\Delta t}{m\Delta V} \quad (2)$$

where,  $i(V)$  is voltammetric current,  $m$  (g) represents the mass of active materials,  $\Delta V$  (V) is the potential window,  $v$  (mV s<sup>-1</sup>) is the scan rate,  $I$  (A) is applied current while  $\Delta t$  (s) is total discharging time.<sup>22,23</sup>

The coulombic efficiency of an electrode can be computed by using the following relation

$$\eta = \frac{t_D}{t_C} \times 100\% \quad (3)$$

while  $t_D$  and  $t_C$  are charging and discharging time respectively.<sup>24</sup>

## 3. Results and discussion

### 3.1 Physical characterizations

The crystallinity of WO<sub>3</sub>, RGO-WO<sub>3</sub>, CNT-WO<sub>3</sub>, RGO-CNT-WO<sub>3</sub> materials was studied using X-ray diffraction (XRD, Rigaku

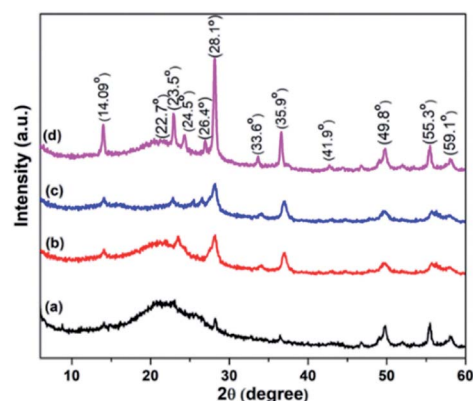

Fig. 3 XRD pattern of (a) WO<sub>3</sub> (b) RGO-WO<sub>3</sub> (c) CNT-WO<sub>3</sub> (d) RGO-CNT-WO<sub>3</sub> nanostructures.

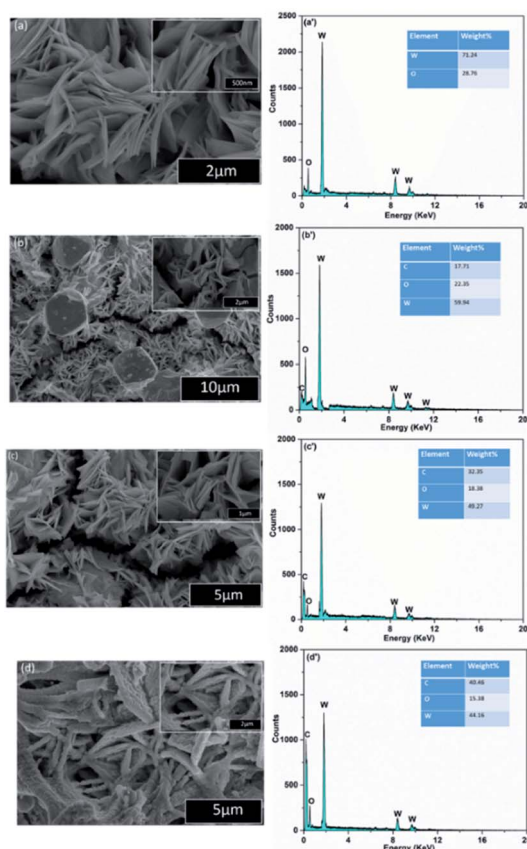

Fig. 4 SEM images of (a) WO<sub>3</sub> (b) RGO-WO<sub>3</sub> (c) CNT-WO<sub>3</sub> (d) RGO-CNT-WO<sub>3</sub> nanostructures and the corresponding EDS graphs of (a') WO<sub>3</sub> (b') RGO-WO<sub>3</sub> (c') CNT-WO<sub>3</sub> (d') RGO-CNT-WO<sub>3</sub>.

diffractometer) with Cu K $\alpha$  radiation ( $\lambda = 1.5416 \text{ \AA}$ ). Scanning electron microscopy (SEM, Hitachi S4800, operating voltage 10 kV) was used to examine the morphologies of the produced materials. Raman spectrometer (Jobin Yvon HR 800) equipped with He-Ne laser was used to record Raman spectra at an excitation source of 632.8 nm wavelength.

**3.1.1 XRD analysis.** To determine the crystalline nature of samples, X-ray diffraction is employed. The range to analyse spectra was  $5^\circ$  to  $60^\circ$ . Fig. 3 manifests the XRD spectra of WO<sub>3</sub>, RGO-WO<sub>3</sub>, CNT-WO<sub>3</sub>, RGO-CNT-WO<sub>3</sub> nanostructures. All assigned peaks referred to monoclinic phase of tungsten trioxide well matched with JCPDS card no. 83-9950 having space group  $P2_1/n$  ( $a = 7.297 \text{ \AA}$ ,  $b = 7.539 \text{ \AA}$ ,  $c = 7.689 \text{ \AA}$ ). No impurity peak is found in this pattern. The favourable oriented growth is observed in crystallite planes (100), (002), (200), (112), (220), (122), (222), (232), (420), (224), (402) having value of  $2\theta$  as  $14.09^\circ$ ,  $22.7^\circ$ ,  $24.5^\circ$ ,  $28.1^\circ$ ,  $33.6^\circ$ ,  $35.9^\circ$ ,  $41.9^\circ$ ,  $49.8^\circ$ ,  $55.3^\circ$ ,  $59.1^\circ$ ,  $63.7^\circ$ .<sup>25–27</sup> The high crystallinity helps to improve the overall electrochemical performance of synthesized electrodes.<sup>28</sup> A peak observed at  $23.5^\circ$  specified to the successful conversion of graphene oxide into reduced graphene oxide through hydrothermal route. The XRD patterns of composites did not show any peak of GO at  $10^\circ$ , indicating that the GO reduction was done properly throughout the composite preparation. The presence of CNTs is confirmed by the peak located at  $26.4^\circ$ .<sup>29</sup>

**3.1.2 SEM analysis.** The morphological characteristics of WO<sub>3</sub>, RGO-WO<sub>3</sub>, CNT-WO<sub>3</sub>, RGO-CNT-WO<sub>3</sub> were studied by scanning electron microscopy. Fig. 4 shows that WO<sub>3</sub> nano-composites have uniform 3 dimensional architectures having flowerlike shape. In addition, highly magnified images endorse that these architectures are composed of many sheet-like petals and no breakage or collapse is observed in these petals. In RGO/CNT based tungsten trioxide nanocomposites, these flower like architectures of WO<sub>3</sub> are assembled very well on reduced graphene sheets which are connected to CNTs having strong interfacial contact which ultimately provides the fastest electron transport and hence enhances the performance of electrode.<sup>29</sup>

The pores in RGO/CNTs network provide vast channels for ion-transportation and inter-connected sheet works as conduction skeleton for electron transportation. This unique feature also provides enhanced contact area with electrolytic ions which results in path length reduction thus leads to promotion of fast electrons and ion transportation. This will overall improve the electrochemical performance.<sup>30</sup> The corresponding EDS spectra of all nanocomposites, displayed in Fig. 4a'–d' indicate the presence of C, O and W elements without any other impurities.

**3.1.3 Raman analysis.** The phonons, defects and electron-electron/phonon-electron interactions in different materials are studied through Raman analysis. Fig. 5 presents the Raman spectra of WO<sub>3</sub>, RGO-WO<sub>3</sub>, CNT-WO<sub>3</sub>, RGO-CNT-WO<sub>3</sub> nanostructures.

As depicted in Fig. 5, there are six modes (Raman active) for tungsten trioxide (WO<sub>3</sub>). A G peak, D peak and 2D bands for RGO-CNTs are located at  $1331 \text{ cm}^{-1}$ ,  $1589 \text{ cm}^{-1}$  and  $2650 \text{ cm}^{-1}$  respectively. A D-band referred to defects present in carbon nanostructures whereas scattering of  $\text{sp}^2$  carbon atoms results in G-peak. Also, 2D bands are created as a result of dual resonance processes. The peak located at  $936.9 \text{ cm}^{-1}$  attributes to W=O bond stretching, whereas stretching vibration of oxygen (O–W–O) is related to the peaks  $763.1 \text{ cm}^{-1}$  and  $806.2 \text{ cm}^{-1}$  respectively. The bending vibration of (W–O–W) occurs and

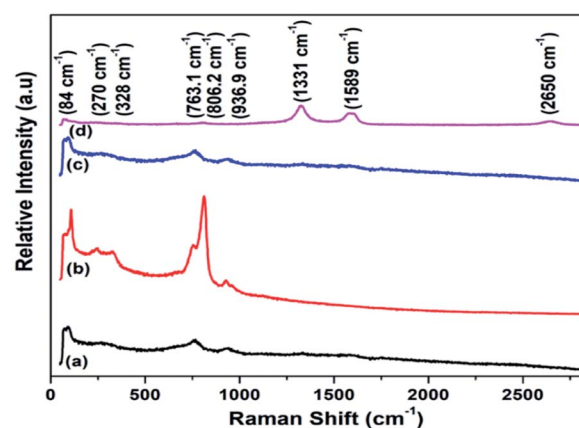

Fig. 5 Raman spectra of (a) WO<sub>3</sub> (b) RGO-WO<sub>3</sub> (c) CNT-WO<sub>3</sub> (d) RGO-CNT-WO<sub>3</sub> nanostructures.

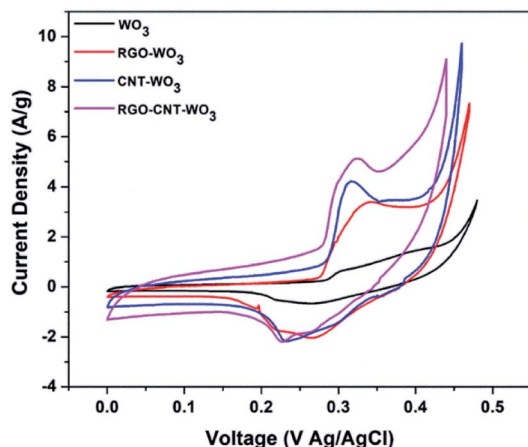

Fig. 6 Comparison of CV curves of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes at a scan rate of  $5 \text{ mV s}^{-1}$ .

results in a peak at  $264 \text{ cm}^{-1}$  while peak located at  $328 \text{ cm}^{-1}$  correlates to  $\nu(\text{W-OH}_2)$  vibrations. Additionally, a pair of peaks are found at  $84 \text{ cm}^{-1}$  and  $270 \text{ cm}^{-1}$ . Also, in addition, two low-intensity peaks referred to D & G bands, representing the presence of RGO-CNTs in  $\text{CNT-WO}_3$ ,  $\text{RGO-WO}_3$  and  $\text{RGO-CNT-WO}_3$  nanostructures.<sup>31–34</sup>

### 3.2 Electrochemical characterizations

To prepare the working electrodes, the active materials (80 wt%), acetylene black (10 wt%) and PVDF (solvent is NMP) are mixed and pressed on a nickel foam and finally dried in an oven at a temperature of  $120^\circ\text{C}$  for 10 hours. The cyclic voltammetry (CV), galvanostatic charge discharge (GCD), cyclic stability and electrochemical impedance spectroscopy (EIS) were employed to study the electrochemical features of as-prepared electrodes in a three-electrode cell configuration in 3 M KOH electrolytic solution while this cell configuration contains a Pt wire acting as counter electrode, as-prepared electrodes as working electrode and Ag/AgCl electrode worked as reference electrode. A gold wire is used as current collector. These measurements were taken in a potential range 0–0.48 V at various scan rates. Different current densities ( $2\text{--}8 \text{ A g}^{-1}$ ) were employed to record GCD curves. The EIS spectra was taken for frequency range (1–105 Hz) using 10 mV AC perturbation. Cyclic voltammetry (CV) was employed to inspect stability performance of ( $\text{RGO-CNT-WO}_3$ ) hybrid electrode. The CV cycles were run for 5000 cycles at a scan rate of  $1000 \text{ mV s}^{-1}$  and two CV curves were recorded at scan rate  $5 \text{ mV s}^{-1}$  initially and after

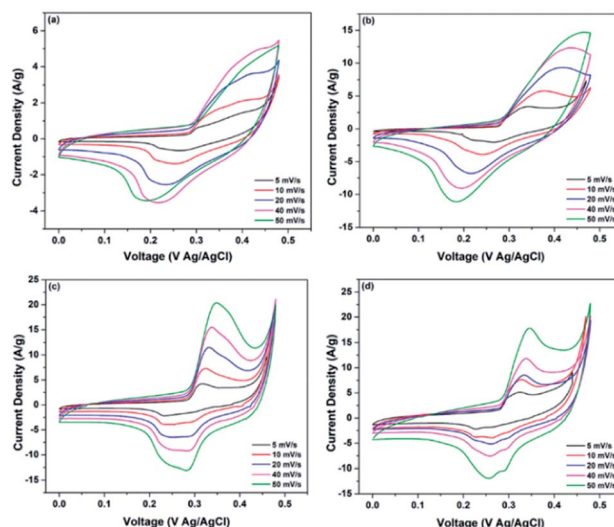

Fig. 7 Comparison of CV curves of (a)  $\text{WO}_3$ , (b)  $\text{RGO-WO}_3$ , (c)  $\text{CNT-WO}_3$ , (d)  $\text{RGO-CNT-WO}_3$  electrodes at various scan rates.

5000th cycle and then capacitance retention of prepared electrode was calculated.

**3.2.1 CV analysis.** The super-capacitive behaviour of as-synthesized electrodes was studied through CV analysis. Fig. 6 manifests the comparison of CV curves of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$  and  $\text{RGO-CNT-WO}_3$  electrodes at a scan rate of  $5 \text{ mV s}^{-1}$ . A couple of redox peaks are traced in all CV curves owing to pseudocapacitive behaviour arises due to electrochemical reactions. It has been distinctly seen that  $\text{RGO-CNT-WO}_3$  electrode displays greater integrated area in comparison to other electrodes implying the fast interaction among RGO/CNT and tungsten trioxide nanostructures which speed up the electrochemical activity, hence the effective and fast transfer of charges.<sup>35</sup>

Eqn (1) was used to compute the specific capacitance of each electrode. Among all the electrodes,  $\text{RGO-CNT-WO}_3$  composite owns higher capacitance of  $691.38 \text{ F g}^{-1}$  as compared to other electrodes (Table 1). The higher accessible surface area facilitates faster ion adsorption which leads to efficient transportation of charges and ion intercalation<sup>36</sup> resulting in higher specific capacitance of  $\text{RGO-CNT-WO}_3$ . The supercapacitive performance of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  from  $5\text{--}50 \text{ mV s}^{-1}$  are displayed in Fig. 7.

As expected, the increase in scan rate resulted in increased current density and integrated area with nearly little change in

Table 1 Specific capacitances of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes at different scan rates

Sample	Specific capacitance ( $\text{F g}^{-1}$ )				
	$5 \text{ mV s}^{-1}$	$10 \text{ mV s}^{-1}$	$20 \text{ mV s}^{-1}$	$30 \text{ mV s}^{-1}$	$50 \text{ mV s}^{-1}$
$\text{WO}_3$	212.93	156.3	129.4	120.6	67.32
$\text{RGO-WO}_3$	497.6	387.91	312.8	286.3	199.08
$\text{CNT-WO}_3$	567.99	481.97	381.07	334.3	247.94
$\text{RGO-CNT-WO}_3$	691.38	627.03	344.03	304.6	253.09

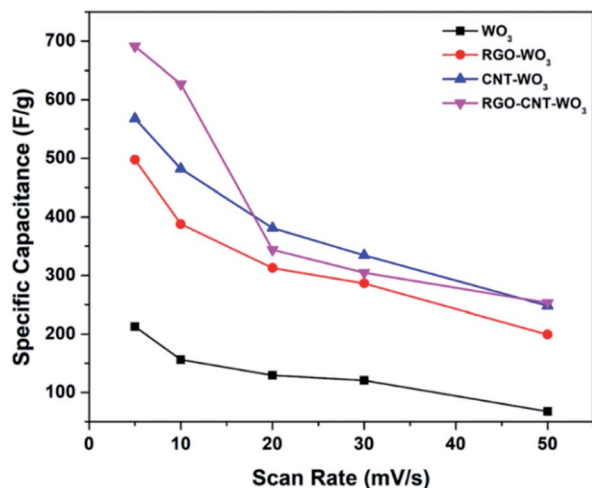

Fig. 8 The variation of specific capacitance with scan rates of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes at various scan rates.

shape of CV curves which reflects the higher reversibility and stability of all electrodes. Nevertheless, as presented in Fig. 7d, even at higher scan rates of  $50 \text{ mV s}^{-1}$ , there is no remarkable change in shapes of CV curves which indicates behaviour close to ideal supercapacitor and high rate performance as compared to other electrodes.

The specific capacitance variation with scan rates is depicted in Fig. 8. It can be clearly seen that the increase in scan rate reduces specific capacitance because the redox reactions occur only onto the surface as inner electroactive sites for ion intercalation are not available completely and *vice versa*.

**3.2.2 GCD analysis.** Galvanostatic charge–discharge analysis is another reliable method for enquiry of electrochemical performance of all electrodes. The GCD curves of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$  and  $\text{RGO-CNT-WO}_3$  electrodes at  $2 \text{ A g}^{-1}$  in  $3 \text{ M KOH}$  electrolytic solution are shown in Fig. 9. All GCD curves reveal typical triangular discharge plateau which are in good

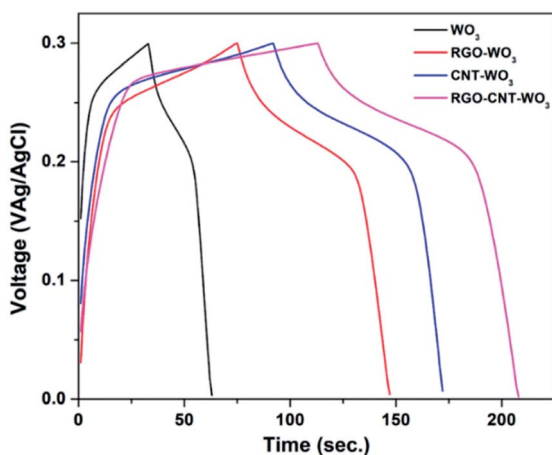

Fig. 9 Comparison of GCD curves of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes at a current density of  $2 \text{ A g}^{-1}$ .

Table 2 Specific capacitances of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes at various current densities

Sample	Specific capacitance ( $\text{F g}^{-1}$ )			
	$2 \text{ A g}^{-1}$	$4 \text{ A g}^{-1}$	$6 \text{ A g}^{-1}$	$8 \text{ A g}^{-1}$
$\text{WO}_3$	199.7	160.27	72.4	52.8
$\text{RGO-WO}_3$	480.6	400.5	238.6	211.47
$\text{CNT-WO}_3$	533.3	425.3	361	318.4
$\text{RGO-CNT-WO}_3$	633.3	562.7	429	346.7

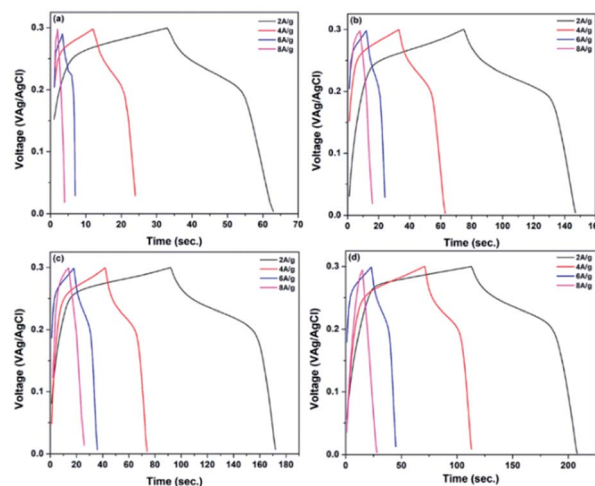

Fig. 10 GCD curves of (a)  $\text{WO}_3$  (b)  $\text{RGO-WO}_3$  (c)  $\text{CNT-WO}_3$  (d)  $\text{RGO-CNT-WO}_3$  electrodes at different current densities.

symmetry, exhibiting pseudocapacitive behaviour. These GCD curves also display redox peaks which is in accordance with CV curves. Eqn (2) has been used to calculate specific capacitance of all electrodes and the obtained values are  $199.7 \text{ F g}^{-1}$ ,  $480.6 \text{ F g}^{-1}$ ,  $533.3 \text{ F g}^{-1}$ ,  $633.3 \text{ F g}^{-1}$  for  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$  and  $\text{RGO-CNT-WO}_3$  respectively at  $2 \text{ A g}^{-1}$ . In agreement to CV curve,  $\text{RGO-CNT-WO}_3$  has longer discharge time, thus exhibiting higher specific capacitance ( $C_s$ ) of  $633.3 \text{ F g}^{-1}$  in comparison of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$  and  $\text{CNT-WO}_3$  electrodes.

Such greater performance of  $\text{RGO-CNT-WO}_3$  can be credited to (i) the short ion diffusion path and facilitates rapid electron transport which is produced as a result of sufficient interfacial contact amongst  $\text{RGO/CNT}$  nanosheets and  $\text{WO}_3$  nanostructures (ii)  $\text{WO}_3$  nanoflowers permit reversible and instantaneous oxidation–reduction reactions to enhance the capacitance (iii) the production of electroactive sites increased due to unique hybrid nanostructures.<sup>37</sup>

The  $\text{RGO-CNT-WO}_3$  electrode possesses specific capacitances of  $633.3$ ,  $562.6$ ,  $429$  &  $340.7 \text{ F g}^{-1}$  at  $2$ ,  $4$ ,  $6$  and  $8 \text{ A g}^{-1}$  respectively [Table 2]. Distinctly, even at a high current density of  $8 \text{ A g}^{-1}$ , the capacitance of the  $\text{RGO-CNT-WO}_3$  electrode remains as high as  $346.7 \text{ F g}^{-1}$ .

To study the effect of higher current densities on specific capacitances, the GCD curves of each electrode at various current densities were obtained as represented in Fig. 10. It is clear that when the current density increases, the discharging

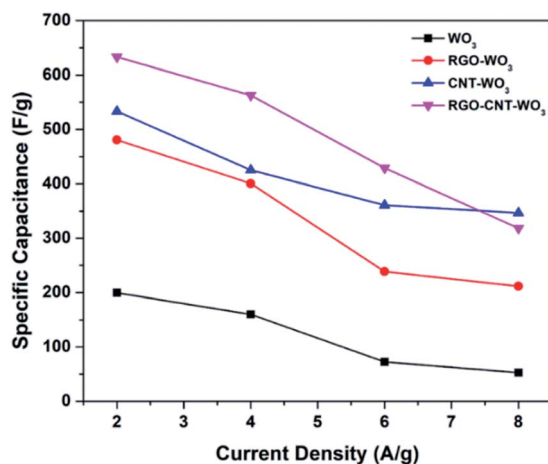

Fig. 11 Relationship of specific capacitance as a function of current density of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes.

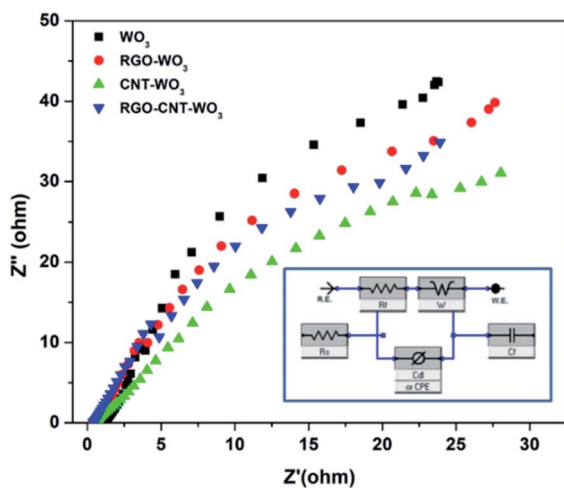

Fig. 12 Comparison of Nyquist plots of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$  and  $\text{RGO-CNT-WO}_3$  composite electrodes while inset shows an equivalent fitting circuit of a supercapacitor.

time for all electrodes reduces. This is because at greater current densities, surface synergy between electrode and electrolyte is more likely to occur, resulting in a reduction in specific capacitance and a faster rate of discharge.<sup>38,39</sup> Fig. 11 illustrates the range of specific capacitance of  $\text{RGO-CNT-WO}_3$  electrodes with various current densities  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes with various current densities.

Table 4 Coulombic efficiencies of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes at different current densities

Electrode materials	Coulombic efficiency $\eta$ (%)			
	2 A g <sup>-1</sup>	4 A g <sup>-1</sup>	6 A g <sup>-1</sup>	8 A g <sup>-1</sup>
$\text{WO}_3$	90.6	92.1	95.6	112.4
$\text{RGO-WO}_3$	93.1	97.3	110	99.07
$\text{CNT-WO}_3$	93.3	95.7	98.2	99.9
$\text{RGO-CNT-WO}_3$	94.3	96.2	97.5	99.99

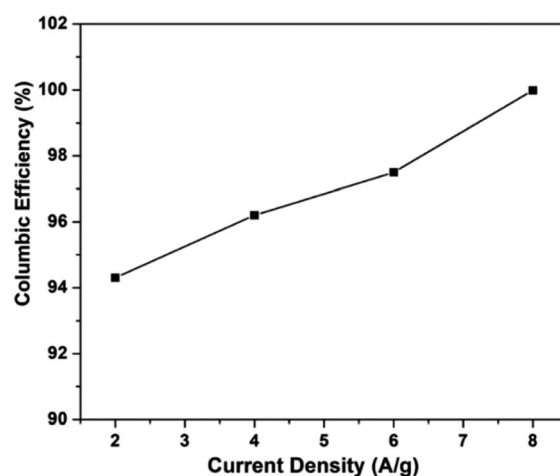

Fig. 13 Coulombic efficiency as a function of current density of  $\text{RGO-CNT-WO}_3$  composite electrode.

**3.2.3 EIS analysis.** The capacitive and resistive behaviour of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes were explored using EIS. Fig. 12 illustrates the impedances of as-prepared electrodes in a 3 M KOH electrolytic solution over a frequency range of 1 Hz–100 kHz at 10 mV AC amplitude.

It is noticeable that on the real component *i.e.* the  $Z'$  axis, the diameter of a semicircle in high frequency zone is associated to the  $R_{ct}$ , indicating greater ion diffusion into electrode pores. In the high frequency band, the Nyquist plot of all electrodes displays no semicircle, indicating optimal super-capacitive behaviour.<sup>29,40</sup> In comparison to other electrodes, the  $\text{RGO-CNT-WO}_3$  has a relatively low charge transfer resistance of 5.182  $\Omega$ . A vertical curve larger than 45° in the low-frequency zone suggests considerable super-capacitive activity with low diffusion resistance in the electrodes. The analogous circuit (inset) was used to investigate the produced impedance spectra, and

Table 3 Different parameters obtained from fitting of EIS curves of  $\text{WO}_3$ ,  $\text{RGO-WO}_3$ ,  $\text{CNT-WO}_3$ ,  $\text{RGO-CNT-WO}_3$  electrodes

Sample	Series resistance, $R_s$ ( $\Omega$ )	Charge-transfer resistance, $R_{ct}$ ( $\Omega$ )	Constant phase element, $C_{PE}$	Warburg impedance, $W$ ( $\Omega$ )
$\text{WO}_3$	1.051	8.773	0.0045	$661.6 \times 10^{-3}$
$\text{pRGO-WO}_3$	0.350	8.508	0.5004	$652.3 \times 10^{-3}$
$\text{CNT-WO}_3$	0.542	9.354	0.0064	$638.8 \times 10^{-3}$
$\text{RGO-CNT-WO}_3$	0.388	5.182	0.0052	$597.7 \times 10^{-3}$

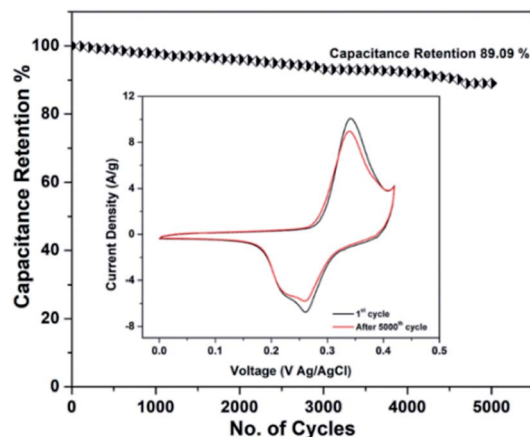

Fig. 14 Cyclic stability of RGO-CNT-WO<sub>3</sub> composite electrode at 1000 mV s<sup>-1</sup> for 5000 cycles. The inset shows the CV curves obtained at 5 mV s<sup>-1</sup> before and after 5000 cycles.

the results are provided in Table 3, where  $C_{PE}$  stands for constant phase element. The RGO/CNT conductive network that governs fast electron transfer channels and WO<sub>3</sub> nanoflowers that facilitate electrolyte penetration and reduce ion and electron diffusion routes are responsible for the improved electrochemical performance.<sup>41</sup>

**3.2.4 Coulombic efficiency.** The coulombic efficiencies of all electrodes are calculated using eqn (3) to determine their reversibility of redox processes, and the results are reported in [Table 4].

It is noticed that the RGO-CNT-WO<sub>3</sub> electrode has the highest coulombic efficiency of 94.3% that is more than 93.3%, 93.1% and 90.6% for WO<sub>3</sub>, RGO-WO<sub>3</sub>, CNT-WO<sub>3</sub> accordingly at a current density of 2 A g<sup>-1</sup>. Fig. 13 shows the coulombic efficiency vs. current density, revealing the strong reversibility of the redox processes of the RGO-CNT-WO<sub>3</sub> electrode. Furthermore, at a greater current density of 8 A g<sup>-1</sup>, the coulombic efficiency of WO<sub>3</sub> exceeds 100%. At 6 A g<sup>-1</sup>, the RGO-WO<sub>3</sub> electrode material achieves a coulombic efficiency of 110

percent. The increased ( $\eta$ ) value (>100%) of RGO-WO<sub>3</sub> at 6 A g<sup>-1</sup> might be attributable to the breakdown of electrode material, which produces extra charges during the discharging cycle.<sup>42</sup>

**3.2.5 Cyclic stability.** Fig. 14 shows the cyclic performance of the RGO-CNT-WO<sub>3</sub> electrode over 5000 cycles, which is achieved by repeating the CV curves at 1000 mV s<sup>-1</sup> between the potential 0–0.48 V. The RGO-CNT-WO<sub>3</sub> electrode has a remarkable capacitance retention of 89.09 percent calculated through CV cycles obtained at 5 mV s<sup>-1</sup> before and after 5000 cycles. These CV curves are shown in the inset of Fig. 14 at 5 mV s<sup>-1</sup> for the first cycle and after the 5000th cycle.

The improved electro-chemical performance of RGO-CNT-WO<sub>3</sub> can be accredited to tungsten trioxide and CNT/RGO nanostructures, which increase the electrolyte-electrode contact area and hence favour ion transport, resulting in a higher rate capability.<sup>43</sup> These findings suggest that RGO-CNT-WO<sub>3</sub> is a tremendous candidate for use in well-efficient energy storage devices. The comparison of electrochemical performance of (RGO-WO<sub>3</sub>), (CNT-WO<sub>3</sub>), and (RGO-CNT-WO<sub>3</sub>) with the reported literature was done and it is listed in Table 5. The results manifest that the prepared electrodes have capacitance and cyclic stability comparable to or higher than the others, suggesting the superior electrochemical performance. Also, to the best of our knowledge, RGO-CNT-WO<sub>3</sub> electrode has not reported in the literature yet.

## 4. Conclusions

In summary, this study shows a simplistic synthesis of graphene oxide (GO) and tungsten trioxide (WO<sub>3</sub>) nanostructures, followed by hydrothermal hybridization of this transition metal oxide with carbon materials (graphene, CNTs) to produce binary and ternary nanocomposites. XRD analysis confirms the monoclinic phase and high crystallinity of WO<sub>3</sub>. SEM investigation demonstrates the RGO/CNT network integrated with WO<sub>3</sub> nanoflowers in binary and ternary nanocomposites. Many of the vibrational modes of WO<sub>3</sub> and D, G peaks of RGO/CNTs have been confirmed through Raman investigation. According to electrochemical results, the (RGO-CNT-WO<sub>3</sub>) electrode

Table 5 Comparison of the electrochemical performance of all prepared electrodes with previously reported electrodes

Electrode materials	Synthesis method	Surface morphology	Electrolyte used	Specific capacitance ( $C_s$ )	Capacitance retention	Ref.
Graphene nanosheets-tungsten oxide GNS-W	Facile solution approach	WO <sub>3</sub> platelets	1 M H <sub>2</sub> SO <sub>4</sub>	143.6 F g <sup>-1</sup>		40
Feather duster-like CNT@WO <sub>3</sub>	Microwave heating method	WO <sub>3</sub> nanosheet arrays	0.5 M H <sub>2</sub> SO <sub>4</sub>	496 F g <sup>-1</sup> at 1 A g <sup>-1</sup>	96.3% after 8000 cycles	44
WO <sub>3</sub> ·2H <sub>2</sub> O/bamboo charcoal	Y-Irradiation	Irregular forms	6 M KOH	391 F g <sup>-1</sup> at 0.5 A g <sup>-1</sup>	82% retention after 10 000 cycles	45
HRG//m-WO <sub>3</sub> ASC	Hydrothermal method	WO <sub>3</sub> nanoplates	1 M H <sub>2</sub> SO <sub>4</sub>	389 F g <sup>-1</sup> at 0.5 A g <sup>-1</sup>	92% after 5000 cycles	46
WO <sub>3</sub> -rGO hybrids	Hydrothermal method	Micro-rod like morphology	3 M KOH	801.6 F g <sup>-1</sup> at 4 A g <sup>-1</sup>	75.7% after 5000 cycles	47
RGO-CNT-WO <sub>3</sub>	Hydrothermal method	WO <sub>3</sub> nanoflowers	3 M KOH	633.3 F g <sup>-1</sup> at 2 A g <sup>-1</sup>	89.09% after 5000 cycles	Present work

among all pure and binary nanocomposite electrodes has a superb specific capacitance of  $633.3 \text{ F g}^{-1}$  at a current density of  $2 \text{ A g}^{-1}$ , a coulombic efficiency of 94.3% at  $2 \text{ A g}^{-1}$ , and specific capacitance retention of about 89.09% for 5000 cycles at a scan rate of  $1000 \text{ mV s}^{-1}$ . In short, (RGO-CNT- $\text{WO}_3$ ) nanocomposite electrode exhibits superior specific capacitance, reversibility, cyclic stability, coulombic efficiency and low resistances making it suitable for use in supercapacitors. For high-performance supercapacitor applications, this facile methodology also provides an easy way to synthesize novel electrode materials with improved electrochemical properties.

## Conflicts of interest

There are no conflicts to declare.
