# High performance enhancement-mode thin-film transistor with graphene quantum dot-decorated $\text{In}_2\text{O}_3$ channel layers

 Xiaofen Xu,<sup>a</sup> Gang He, <sup>\*,a</sup> Shanshan Jiang,<sup>\*,b</sup> Leini Wang,<sup>a</sup> Wenhao Wang,<sup>a</sup> Yanmei Liu<sup>a</sup> and Qian Gao<sup>\*,a</sup>

Due to the quantum confinement and edge effects, there has been ongoing enthusiasm to provide deep insight into graphene quantum dots (GQDs), serving as attractive semiconductor materials. To demonstrate the potential applications of GQDs in electronic devices, this work presents solution-processed high performance GQD-decorated  $\text{In}_2\text{O}_3$  thin-film transistors (TFTs) based on  $\text{ZrO}_2$  as gate dielectrics. GQDs- $\text{In}_2\text{O}_3/\text{ZrO}_2$  TFTs with optimized doping content have demonstrated high electrical performance and low operating voltage, including a larger field-effect mobility ( $\mu_{\text{FE}}$ ) of  $34.02 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ , a higher  $I_{\text{on}}/I_{\text{off}}$  of  $4.55 \times 10^7$ , a smaller subthreshold swing (SS) of  $0.08 \text{ V dec}^{-1}$ , a lower interfacial trap states ( $D_{\text{it}}$ ) of  $5.84 \times 10^{11} \text{ cm}^{-2}$  and threshold voltage shift of  $0.07 \text{ V}$  and  $0.12 \text{ V}$  under positive bias stress (PBS) and negative bias stress (NBS) for 3600 s, respectively. As a demonstration of complex logic applications, a resistor-loaded unipolar inverter based on GQDs- $\text{In}_2\text{O}_3/\text{ZrO}_2$  has been built, demonstrating full swing characteristic and high gain of 10.63. Low-frequency noise (LFN) characteristics of GQDs- $\text{In}_2\text{O}_3/\text{ZrO}_2$  TFTs have been presented and it was concluded that the noise source can be attributed to the fluctuations in mobility. As a result, it can be concluded that solution-derived GQD-optimized oxide-based TFTs will manifest potential applications in electronic devices.

## Introduction

Graphene quantum dots (GQDs) are derivatives of graphene with nanometer size, and have common characteristics of graphene and quantum dots.<sup>1</sup> They have a non-zero bandgap because of quantum confinement,<sup>2</sup> resulting in their unique properties such as large surface area, excellent solubility, edge effects *etc.*<sup>3–5</sup> As a result, GQDs are becoming promising semiconductor nanomaterials for applications in biological imaging,<sup>6</sup> ultrasensitive sensors,<sup>7</sup> supercapacitors,<sup>8,9</sup> and electronic and opto-electronic devices.<sup>3,10–13</sup>

$\text{In}_2\text{O}_3$ , a representative of transparent n-type semiconductors with a wide band gap of 3.6 eV, is one of the most widely used materials in various fields ranging from optoelectronic devices to thin film transistors (TFTs) due to its lower processing temperature, environment friendliness and good optoelectronic properties.<sup>14–16</sup> Due to its potential application in next-generation display devices,  $\text{In}_2\text{O}_3$ -based oxide TFTs have attracted more attention.<sup>17–19</sup> Even though the attracting properties of  $\text{In}_2\text{O}_3$  TFTs, but there exist too much oxygen vacancies ( $V_{\text{O}}$ ) in  $\text{In}_2\text{O}_3$  thin films, leading to the more formation of more electrons and the deteriorated devices performance.<sup>20</sup> It has

reported that  $V_{\text{O}}$ -related defects and superabundant mobile electrons will result in higher off-current ( $I_{\text{off}}$ ) and poor bias stress stability.<sup>19,21</sup>

With the aim of improving the electrical stability, great progress has been made in incorporating carrier suppressor dopants into the channel layers of the  $\text{In}_2\text{O}_3$ -based TFTs. To date,  $\text{In}_2\text{O}_3$  films doped by gallium,<sup>22</sup> zinc,<sup>23</sup> tin,<sup>24</sup> yttrium,<sup>25</sup> and magnesium<sup>26</sup> have been achieved to optimize the TFTs performance. However, their preparations and applications are limited because these doped elements are usually scarce and toxicant. Due to their unique electron transport properties, GQDs may play a key role in  $\text{In}_2\text{O}_3$ -based TFTs devices.<sup>11</sup> Based on Shan's investigation, it can be noted that TFTs modified by GQDs are desirable.<sup>27,28</sup> In spite of the attractive electrical properties, the performance improvement mechanism of GQDs decorated  $\text{In}_2\text{O}_3$ -based TFTs is still unclear and requires further study. Therefore, based on the research perspective and further technology application, developing an effective and simple method to prepare GQDs-decorated TFTs is urgently needed. Up to now, various methods have been adopted to fabricate oxide-based TFTs, such as atomic layer deposition (ALD) and sputtering, which highly depend on vacuum-based ambient. What's more, the complicated process and high costs of fabrication inhibit its potential application. By contrast, solution-based process has been paid more attention due to its advantages, including easy operation, low cost, easy controllability, and

large-scale productivity. Therefore, great efforts have been made in preparing solution-driven oxide TFTs devices.<sup>29–31</sup>

In this work, based on a solution-based route, a simple and feasible way has been pursued to synthesize GQDs-decorated In<sub>2</sub>O<sub>3</sub> thin films. Furthermore, a systematical investigation was conducted to reveal the variation in microstructure and component of GQDs-decorated In<sub>2</sub>O<sub>3</sub> films with different doping level. To demonstrate the potential possibility of GQDs in CMOS logics, their applications in GQD-In<sub>2</sub>O<sub>3</sub> TFTs and resistor-loaded inverters based on solution-processed ZrO<sub>x</sub> gate dielectrics by device engineering were also demonstrated, and then evaluated carefully. Experiment results have revealed that the optimized GQD-In<sub>2</sub>O<sub>3</sub> TFTs and resistor-loaded inverter with full swing characteristics have been achieved. The improvement in performance of In<sub>2</sub>O<sub>3</sub>-based TFTs by GQDs doping engineering has been discussed in detail.

## Experimental

GQDs were synthesized by our reported method.<sup>32</sup> The p-type heavily doped Si wafers were chosen as the substrates. Firstly, 0.1 M In<sub>2</sub>O<sub>3</sub> and 0.1 M ZrO<sub>x</sub> solution was obtained by dissolving 0.3 g In(NO<sub>3</sub>)<sub>3</sub>·xH<sub>2</sub>O (99%) and 0.64 g ZrOCl<sub>2</sub>·8H<sub>2</sub>O (99%) in 10 mL 2-methoxyethanol (2-ME). Meanwhile, 1 mg, 2 mg and 3 mg GQDs were mixed with the In<sub>2</sub>O<sub>3</sub> precursor solution, respectively. All the solution were subjected to 8 hour agitation and 12 hour aging. Then, the ZrO<sub>x</sub> precursor solution was spun thrice on the Si wafers under speed of 4500 rpm and baked at 200 °C for 10 min. After UV treatment for 30 min, the as-deposited films experienced 600 °C annealing treatment for 2 h. Moreover, the pure In<sub>2</sub>O<sub>3</sub> and GQDs-decorated In<sub>2</sub>O<sub>3</sub> precursor solution was spun once on the ZrO<sub>x</sub> dielectric layer under speed of 2500 rpm and baked at 150 for 10 min, respectively. The samples were annealed at 280 °C in air ambient for 1 h. Finally, 100 nm thick Al thin film was deposited by thermal evaporation to form source and drain electrodes by a shadow mask with width of 1000 μm and length of 200 μm. TFTs with pure In<sub>2</sub>O<sub>3</sub> channel layer were fabricated in the same way. For convenience, the corresponding samples were denoted as GQDs-In<sub>2</sub>O<sub>3</sub>-1, GQDs-In<sub>2</sub>O<sub>3</sub>-2, and GQDs-In<sub>2</sub>O<sub>3</sub>-3 with the concentration of GQDs of 0.1 mg ml<sup>-1</sup>, 0.2 mg ml<sup>-1</sup>, and 0.3 mg ml<sup>-1</sup>, respectively. The crystal structures of GQDs-In<sub>2</sub>O<sub>3</sub> and In<sub>2</sub>O<sub>3</sub> thin films spin-coated on Si substrates were investigated by X-ray diffractometer (XRD, Empyrean S3, Netherlands) with a Cu Kα radiation. The surface morphologies of the thin films were investigated by atomic force microscopy (AFM, 5500M, Hitachi, Japan). X-ray photoelectron spectroscopy (XPS) analyses were carried out by using ESCALAB 250Xi system (Thermo Fisher Scientific, USA) with Al Kα radiation (1486.6 eV). To study the thermal behavior of the precursor solution in air, a thermogravimetric analyzer (TGA, STA449F3) was carried out at a heating rate of 10 °C min<sup>-1</sup>. The UV visible spectroscopy (UV-Vis-2550, Shimadzu) was used to measure the optical properties of GQDs-In<sub>2</sub>O<sub>3</sub> and In<sub>2</sub>O<sub>3</sub> thin films spin-coated on quartz substrates. The cross-sectional images of the GQDs-In<sub>2</sub>O<sub>3</sub> TFT device were obtained using transmission electron microscope (TEM, JEOL-F200). The electrical performances of the integrated

TFTs and resistor-loaded unipolar inverter were measured under an air ambient by a semiconductor parameter analyzer (Agilent B1500A and Keithley 2636B) in a dark box. The low frequency noise (LFN) characteristics of the GQDs-In<sub>2</sub>O<sub>3</sub> and In<sub>2</sub>O<sub>3</sub> TFTs was detected by semiconductor parameter analyzer (PDA FS-380). The field-effect mobility ( $\mu_{FE}$ ) of the TFTs was calculated by the following formula:

$$I_{DS} = \left( \frac{W}{2L} C_i \mu_{FE} \right) (V_{GS} - V_{TH})^2 \quad (1)$$

where  $W$  is the channel width,  $L$  is the channel length,  $V_{GS}$  is the source-gate voltage,  $I_{DS}$  is the saturation current, and  $C_i$  is the areal capacitance of the ZrO<sub>x</sub> dielectric layer. The interface states density ( $D_{it}$ ) can be inferred using the following equation,

$$D_{it} = \left[ \frac{SS \log(e)}{kT/q} - 1 \right] \frac{C_i}{q} \quad (2)$$

where  $k$ ,  $T$ ,  $SS$ , and  $q$  are the Boltzman's constant, the absolute temperature, the subthreshold swing and the charge quality, respectively.

## Results and discussion

To investigate the thermal behavior of In<sub>2</sub>O<sub>3</sub> precursor powders with different GQDs doping concentrations, corresponding measurements were performed using TGA under nitrogen ambient conditions, and the result is depicted in Fig. 1. As shown in Fig. 1(a), three steps of weight loss occurring from 50 °C to 390 °C have been observed. The first step of weight loss from 50 °C to 150 °C can be attributed to the evaporation of the residual solvent from the precursor powder.<sup>33</sup> The second weight loss occurs between 150 °C and 260 °C, In(NO<sub>3</sub>)<sub>3</sub> starts to decompose and turn into In(OH)<sub>3</sub>, indicating the decomposition, hydrothermal, and the thermal dihydroxylation reaction of In(NO<sub>3</sub>)<sub>3</sub>. According to the previous reports, it can be noted that In(OH)<sub>3</sub> can be transformed into orthorhombic InOOH with metastable state, an intermediate product. It is worth noting that the weight decreases abruptly between 260 °C to 390 °C. This stage represents the dehydroxylation and thermal decomposition of the intermediate products of InOOH, leading to the formation of In<sub>2</sub>O<sub>3</sub>. After 390 °C, no evident change in the weight loss has been detected, indicating that the In<sub>2</sub>O<sub>3</sub> thin films are almost completely formed. Current observations is in good agreement with previous reports that crystallization of the In<sub>2</sub>O<sub>3</sub> can be ultimately achieved above 390 °C.<sup>34,35</sup> After doping by GQDs, the reduction in the transfer temperature has been found, suggesting that GQDs doping can reduce the temperature of In<sub>2</sub>O<sub>3</sub> film preparation. This is consistent with previous reports that graphene-like materials are accompanied by strong gas release, resulting in rapid thermal expansion.<sup>36</sup>

As depicted in Fig. 1(b), the variation in the microstructure of In<sub>2</sub>O<sub>3</sub> thin films with different GQDs doping concentrations was investigated by XRD. No characteristic peaks of In<sub>2</sub>O<sub>3</sub> and GQDs-In<sub>2</sub>O<sub>3</sub> thin films are observed, regardless of the GQDs doping concentrations, meaning that all the films are in an amorphous state. It is well known that the amorphous films have the advantage of large area uniformity, smooth surface,

Fig. 1 (a) Thermal behavior of the pure In<sub>2</sub>O<sub>3</sub> and GQDs-In<sub>2</sub>O<sub>3</sub> precursor powders. (b) XRD patterns of the In<sub>2</sub>O<sub>3</sub> and GQDs-In<sub>2</sub>O<sub>3</sub> thin films.

high stability, low interfacial state density, which are very beneficial to improve the performance of TFT devices.<sup>37</sup>

To verify the potential application of In<sub>2</sub>O<sub>3</sub> and GQDs-In<sub>2</sub>O<sub>3</sub> thin films in the field of transparent electronic devices, all the films spin-coated on quartz substrates were measured by UV-Vis. As depicted in Fig. 2(a), it can be seen that all the thin films are highly transparent with an average optical transmittance of over 90% in the visible range, demonstrating its feasibility in transparent electronic devices. In addition, the transmittance of the GQDs-In<sub>2</sub>O<sub>3</sub> samples increases slightly as the GQDs concentration increases, which can be attributed to the strong photoluminescence of GQDs.<sup>38,39</sup> Based on Tauc plot method, the optical bandgap for the GQDs-In<sub>2</sub>O<sub>3</sub> thin films as a function of GQDs doping concentrations were determined and displayed in Fig. 2(b). Based on Fig. 2(b), it can be seen that the bandgap of In<sub>2</sub>O<sub>3</sub> thin films increases from 3.77 eV to 4.15 eV with GQDs content increasing. As reported, the increased bandgap after GQDs doping is associated with the decreased grain size of thin films and the band gap of GQDs due to its quantum confinement.<sup>2,40,41</sup>

To understand the evolution of the chemical bonding states of In<sub>2</sub>O<sub>3</sub> thin film as function of GQDs doping concentrations, XPS measurements were carried out and displayed in Fig. 3. All the XPS spectra deconvolution was performed by Shirley background subtraction using a Voigt function convoluting

Gaussian and Lorentzian functions. Fig. 3(a) shows the O 1s XPS spectra for the In<sub>2</sub>O<sub>3</sub> and GQDs-In<sub>2</sub>O<sub>3</sub> samples and the binding energies of the O 1s peaks are deconvoluted into three subpeaks centered at 529.9, 531, and 531.8 eV, which can be assigned to the oxygen in oxide lattice (M–O), the oxygen in oxygen vacancies (V<sub>O</sub>), and the oxygen in hydroxyl species (M–OH), respectively.<sup>42,43</sup> Compared with In<sub>2</sub>O<sub>3</sub> sample, the XPS feature of GQDs-In<sub>2</sub>O<sub>3</sub> samples shifts toward the higher binding energy due to the M–OH oxygen atoms are less negatively charged than those in oxides.<sup>44</sup> Based on the XPS results, the fraction of oxygen-related components in In<sub>2</sub>O<sub>3</sub> and GQDs-In<sub>2</sub>O<sub>3</sub> samples was quantitatively discussed and illustrated in Fig. 3(b). It is noteworthy that with increasing GQDs concentration from 0 to 0.3 mg ml<sup>-1</sup>, the fraction of M–O contents increased from 40.0% to 48% and the fraction of M–OH species from 33% to 27% have been observed, which indicates that GQDs doping helps to convert the M–OH to M–O content. The V<sub>O</sub> composition increases from 27% to 28% and then decreases to 25%. This phenomenon is caused by insufficient GQDs element incorporated into In<sub>2</sub>O<sub>3</sub>, so there is not enough GQDs to inhibit the oxygen vacancy caused by In<sub>2</sub>O<sub>3</sub>. Which is consistent with our previous investigations.<sup>33</sup> Fig. 3(c) demonstrates the high-resolution C 1s peaks of the GQDs-In<sub>2</sub>O<sub>3</sub> samples with different GQDs doping concentrations, which can be deconvoluted into four peaks corresponding to the C–C bond in

Fig. 2 (a) Optical transmittance and (b) bandgap of In<sub>2</sub>O<sub>3</sub> thin films with different GQDs concentrations.

Fig. 3 XPS spectra of (a) O 1s, (c) C 1s, and semiquantitative analyses of (b) oxygen-related, (d) carbon-related components in  $\text{In}_2\text{O}_3$  thin films with different GQDs concentration.

aromatic rings (284.8 eV), C-N bond (285.2 eV), C-O bond (286.4 eV), and C=O bond (288.6 eV).<sup>32,45</sup> Based on the evolution of the fraction of carbon-related components (Fig. 3(d)), it is found that the contents of C-O and C=O remain relatively stable and no obvious change has been detected. Meanwhile, the fraction of the C-C slightly decreases and C-N species slightly increases with increasing the GQDs concentration.

To confirm the possibility of solution-driven  $\text{ZrO}_x$  dielectric thin film annealed at 600 °C as the dielectric layer, Al/ $\text{ZrO}_x$ /Si MOS capacitor devices were fabricated and the dielectric properties and leakage current behavior were analyzed by an

impedance analyzer. Fig. 4 displays the areal capacitance as a function of frequency in the range from 20 to 100 kHz. As shown in Fig. 4(a), the areal capacitance of  $\text{ZrO}_x$  thin films annealed at 600 °C is measured to 301 nF  $\text{cm}^{-2}$  at 20 Hz and the calculated dielectric constant is 5.78. Compared to some reported values, the larger area capacitance at 20 Hz has been found, indicating the formation of  $\text{ZrO}_x$  gate dielectric thin film with high quality. For field-effect devices, it is well-known that the dielectric with large area capacitance can induce more carriers at the interface between the semiconductor and the dielectric, thereby reducing the operating voltage. Meanwhile,

Fig. 4 (a) Frequency-dependent areal capacitance of the  $\text{ZrO}_x$  thin films annealed at 600 °C. (b) Leakage current density of the  $\text{ZrO}_x$  thin films annealed at 600 °C. Inset shows the AFM image of  $\text{ZrO}_x$  thin film annealed at 600 °C.

a weaker frequency dispersion of capacitance for 600 °C-annealed  $ZrO_x$  films has been observed, indicating the formation of denser metal-oxide bonding and much lower defect densities in  $ZrO_x$  films such as hydroxyl group or oxygen vacancies in thin films. This will be of benefit to reduce the leakage current because the conduction paths in dielectrics are mainly caused by hydroxyl and grain boundaries. Fig. 4(b) shows the leakage current characteristics of MOS capacitors and a relatively low leakage current density ( $7.5 \times 10^{-8} \text{ A cm}^{-2}$  at 2 V), which is comparable to that of  $SiO_2$ , has been found. The lower leakage current density comes from the gradually decomposition of residuals and reduction in the defect density. The dielectric layers possessing sufficiently low leakage current ensures that TFT devices have low OFF-state current and can operate at low voltage. AFM morphology of  $ZrO_x$  dielectric films annealed at 600 °C is shown in the inset of Fig. 4(b) and RMS of

0.58 nm has been observed. Generally, the preferred smooth surface is conducive to the rapid transmission of carriers in narrow channel without suffering from electronic scattering and the formation of lower leakage current. Indeed, the smooth surface results from the reduction of the interface charge traps and dangling bonds, leading to the production of an excellent interface between the channel layer and the dielectric layer, which will contribute to high performance TFTs. Moreover, the achievement of dielectrics with small RMS will be of benefit to obtain high quality channel layer.<sup>46</sup>

The cross-sectional transmission electron microscopy (TEM) images of the complete devices, for example, with GQDs- $In_2O_3$ -2 TFT shown in Fig. 5(a), confirm the expected thickness of each layer. The images also reveal excellent homogeneity of the films with uniform thickness. The scanning transmission electron microscopy (STEM) images obtained with elemental mappings

Fig. 5 (a) (g) (j) Cross-sectional and zoomed-in area HRTEM images of the TFT with GQDs- $In_2O_3$ / $ZrO_x$ /Si gate dielectrics. (b–f) Elemental mapping images across the cross section of the GQDs- $In_2O_3$ -2 TFT. (b) Cross-sectional and zoomed-in area HRTEM images of the TFT. Inset, the FFT pattern. (h–i) STEM-ABF images of the GQDs- $In_2O_3$ -2 TFT. (k) HRTEM images of the enlarged selected area marked with a red box. (l) The corresponding 2D FFT images.

(Fig. 5(b)–(f)) show high distribution uniformity of the elements with clear demarcation across the layers. All images show a clear boundary case, with no obvious interfaces spreading out or separating from each other, which helps to minimize the trapped charge. Based on STEM-ABF images shown in Fig. 5(h) and (i), it can be noted that many quantum dots are distributed in  $\text{In}_2\text{O}_3$  films. To confirm the exact content of the QDs, the HRTEM images of the enlarged selected area marked with a red box, displayed in Fig. 5(k), shows that the materials have clear discernible lattice structures and the C–C bond is close to the ideal C–C bond for graphite.<sup>47</sup> According to 2D fast Fourier transform (FFT) patterns (Fig. 5(i)), the esthetic hexagonal honeycomb structure with the bond lengths of 1.42 Å for C–C/C=C has been observed,<sup>48</sup> revealing that the GQDs have been successfully incorporated into  $\text{In}_2\text{O}_3$  thin films.

To investigate the feasibility of the GQDs- $\text{In}_2\text{O}_3$  thin films as the channel layers in TFTs,  $\text{In}_2\text{O}_3/\text{ZrO}_x$  and GQDs- $\text{In}_2\text{O}_3/\text{ZrO}_x$  TFTs with bottom-gate and top-contact architectures were fabricated and shown in Fig. 6. The typical output characteristic curves of the  $\text{In}_2\text{O}_3/\text{ZrO}_x$  and GQDs- $\text{In}_2\text{O}_3$ -2/ $\text{ZrO}_x$  TFTs at a  $V_{\text{GS}}$  of 1.5 V are depicted in Fig. 6(a) and (b). It can be noted that these devices represent typical n-channel conduction behavior with clear pinch-off voltage and current saturation. Compared to GQDs- $\text{In}_2\text{O}_3$ -2/ $\text{ZrO}_x$  TFT, the output curves of  $\text{In}_2\text{O}_3/\text{ZrO}_x$  TFT demonstrate the shifting trend towards right side (Fig. 6(a)). In addition, the higher gate voltage  $V_{\text{GS}}$  is, the more the output curve right shifts, which can be attributed to the fact that the ohmic contact between Al electrodes and GQDs- $\text{In}_2\text{O}_3$ -2 thin films is much better than that of  $\text{In}_2\text{O}_3$  thin films. It can be observed that GQDs- $\text{In}_2\text{O}_3$ -2 TFT represents a saturation current

of 28.2  $\mu\text{A}$  at 2.0 V, which is nearly 6 times larger than that of  $\text{In}_2\text{O}_3/\text{ZrO}_x$  TFT. The obvious increase of on-current level of TFTs doped by GQDs can result from the relatively higher mobility of GQDs- $\text{In}_2\text{O}_3$  layers compared to  $\text{In}_2\text{O}_3$  channel layers. The GQDs-embedded  $\text{In}_2\text{O}_3$  TFTs demonstrate reasonably high on-current characteristics and we expect them to show stable unipolar switching characteristics. Fig. 6(c) shows the transfer characteristics of the  $\text{In}_2\text{O}_3$  TFT in comparison with those of the three reference TFTs with different GQDs doping concentrations. The current between the source and the drain was measured at a static drain-source voltage of 2 V while the gate voltage changed from  $-1$  V to 4 V.

To investigate the evolution of the electrical properties of the  $\text{In}_2\text{O}_3$  TFTs as a function of GQDs doping concentrations, key electrical parameters, including the field-effect mobility ( $\mu_{\text{FE}}$ ) and the threshold voltage ( $V_{\text{TH}}$ ), are calculated from the slope of  $I_{\text{DS}}^{1/2}$  vs.  $V_{\text{GS}}$ . All extracted TFTs performance parameters as a function of GQDs doping concentration are summarized in Table 1. It has been found that compared with pure  $\text{In}_2\text{O}_3$  TFT, the  $\mu_{\text{FE}}$  of GQDs- $\text{In}_2\text{O}_3$  TFTs increases obviously. It has been reported that the carrier concentration of oxide semiconductors can be increased obviously with C incorporation.<sup>49</sup> The increase of the  $\mu_{\text{FE}}$  of GQDs- $\text{In}_2\text{O}_3$  TFTs can be attributed to the higher electron mobility of graphene.<sup>50,51</sup> However, excessive doping level of GQDs leads to the reduced  $\mu_{\text{FE}}$ . As a result, it can be concluded that GQDs plays an important role in improving the mobility of TFTs device and the doping level should be controlled accurately. The extracted changes in  $V_{\text{TH}}$  reveals that increasing the doping level of GQDs will lead to the increased positive  $V_{\text{TH}}$ . This case can be attributed to the fact that the

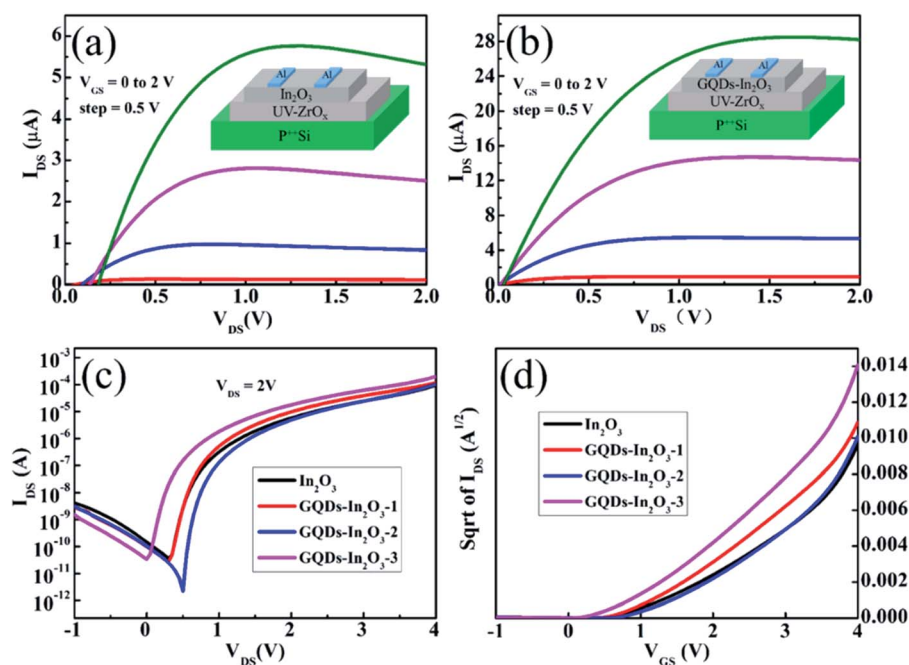

Fig. 6 Output cure of (a)  $\text{In}_2\text{O}_3$  TFT and (b) GQDs- $\text{In}_2\text{O}_3$ -2 TFT. (c) Transfer characteristics of the  $\text{In}_2\text{O}_3$  and GQDs- $\text{In}_2\text{O}_3$  TFTs. (d) Square-root of the transfer characteristics of the  $\text{In}_2\text{O}_3$  and GQDs- $\text{In}_2\text{O}_3$  TFTs. The insets in (a) and (b) show the schematic illustration of the bottom-gate and top-contact  $\text{In}_2\text{O}_3$ -based TFTs.

excess carrier concentration of  $\text{In}_2\text{O}_3$  will be compensated by GQDs and remarkably shift  $V_{\text{TH}}$  towards the positive values necessary for enhancement mode (E-mode) device characteristics has been observed. Based on Table 1, it can be also noted that compared to  $\text{In}_2\text{O}_3$  TFTs, GQDs- $\text{In}_2\text{O}_3$  TFTs has a higher  $I_{\text{on}}/I_{\text{off}}$ , which can be due to the increased  $I_{\text{on}}$  and the decreased  $I_{\text{off}}$ . With increasing the GQDs doping level, the oxygen vacancy and free carrier concentration decrease. As a result,  $I_{\text{on}}/I_{\text{off}}$  initially increases because of the reduced  $I_{\text{off}}$ . However, further increasing the GQDs doping concentration leads to the degradation of the device performance, resulting from the increased trap states near the GQDs- $\text{In}_2\text{O}_3/\text{ZrO}_x$  TFTs interface.

Another electrical parameter, the subthreshold swing (SS), is calculated to be 0.11, 0.10, 0.08, and 0.12  $\text{V dec}^{-1}$  for  $\text{In}_2\text{O}_3$ -based TFTs with different GQDs doping level. As we know, the SS value depends on the traps located in channel/dielectric interface and the lower SS can be expected to achieve a high operation speed and low power consumption. The small SS value of 80  $\text{mV dec}^{-1}$  for GQDs- $\text{In}_2\text{O}_3$ -2 sample is close to the theoretical limit (60  $\text{mV dec}^{-1}$ ), which can originate from the large areal capacitance of the  $\text{ZrO}_x$  dielectric layer and the electronic-clean interface between the channel layer and  $\text{ZrO}_x$ .<sup>52</sup> Based on the extracted SS, the  $D_{\text{it}}$  values of all  $\text{In}_2\text{O}_3$ -based TFTs with different GQDs doping content have been determined and listed in Table 1. Compared to  $\text{In}_2\text{O}_3$ -TFT, the reduction in  $D_{\text{it}}$  values for GQDs- $\text{In}_2\text{O}_3$  TFTs has been observed, indicating the reduction of the defect states and the formation of high quality GQDs- $\text{In}_2\text{O}_3/\text{ZrO}_x$  interface. With its large critical current density and high saturation speed, graphene has great potential for high-speed electronics.<sup>53</sup> Appropriate GQDs doping may reduce the defect density at the interface between the channel layer and the gate dielectric layer, resulting in its small values of SS and  $D_{\text{it}}$  for GQDs- $\text{In}_2\text{O}_3$  TFT. The observed smallest  $D_{\text{it}}$  in GQDs- $\text{In}_2\text{O}_3$ -2 is not only beneficial to carrier transport in the interface region, but also to the operation stability. However, for GQDs- $\text{In}_2\text{O}_3$ -3 TFTs, the sharp increased  $D_{\text{it}}$  has been observed,

which is in agreement with the evolution of the SS value. Excessive GQDs doping into  $\text{In}_2\text{O}_3$  will introduce a large number of oxygen-containing functional groups, which will act as the trap states and trap mobile carriers, leading to the degraded the performance parameter of TFTs.

Based on above analyses, it can be concluded that compared with pure  $\text{In}_2\text{O}_3$  TFT, solution-derived GQDs- $\text{In}_2\text{O}_3$ -2 TFT exhibits impressive enhancement-mode device performance with a relatively smaller  $V_{\text{TH}}$  of 1.22 V, an extraordinary on/off current ratio ( $>10^7$ ), and a higher peak  $\mu_{\text{FE}}$  of 32.02  $\text{cm}^2 (\text{V}^{-1} \text{s}^{-1})$ . These excellent electrical properties are due to the structural flexibility of graphene.<sup>54</sup> To our best knowledge, such a mobility is the highest compared with previous reports on  $\text{In}_2\text{O}_3$ -based TFTs *via* doping engineering route in recent years (indicated in Table 2). All these excellent device performances have guaranteed the potential application of GQDs- $\text{In}_2\text{O}_3$  TFTs in e-book and TFT-LCD. Particularly, all these parameters were obtained at a low operating voltage of 4 V, which is significant for low-power and green electronics.

Since the TFT is the basic unit of integrated circuit, the operational stability of the TFT is a key electrical performance parameter, which determines their commercial applications such as the backplane of AMLCDs and AMOLEDs. The threshold voltage shift of TFTs will cause the decrease of display brightness and directly affect the display effect. To investigate the bias stability of the  $\text{In}_2\text{O}_3$  and GQDs- $\text{In}_2\text{O}_3$ -2 TFTs, positive and negative bias stress (PBS and NBS) measurements were carried out by applying a constant gate bias of 2.0 V while maintaining source and drain electrodes grounded. Fig. 7(a) and (b) display the transfer characteristics of the  $\text{In}_2\text{O}_3$  and GQDs- $\text{In}_2\text{O}_3$ -2 TFTs as a function of the stress time up to 3600 s. It can be seen that the TFT device with pure  $\text{In}_2\text{O}_3$  channel layer suffers from positive threshold voltage shift ( $\Delta V_{\text{TH}}$ ) of 0.69 V during PBS duration (Fig. 7(a)), indicating that more electrons are trapped near/at the dielectric and  $\text{In}_2\text{O}_3$  interface. In contrast, the GQDs- $\text{In}_2\text{O}_3$ -2 TFT demonstrates an improved

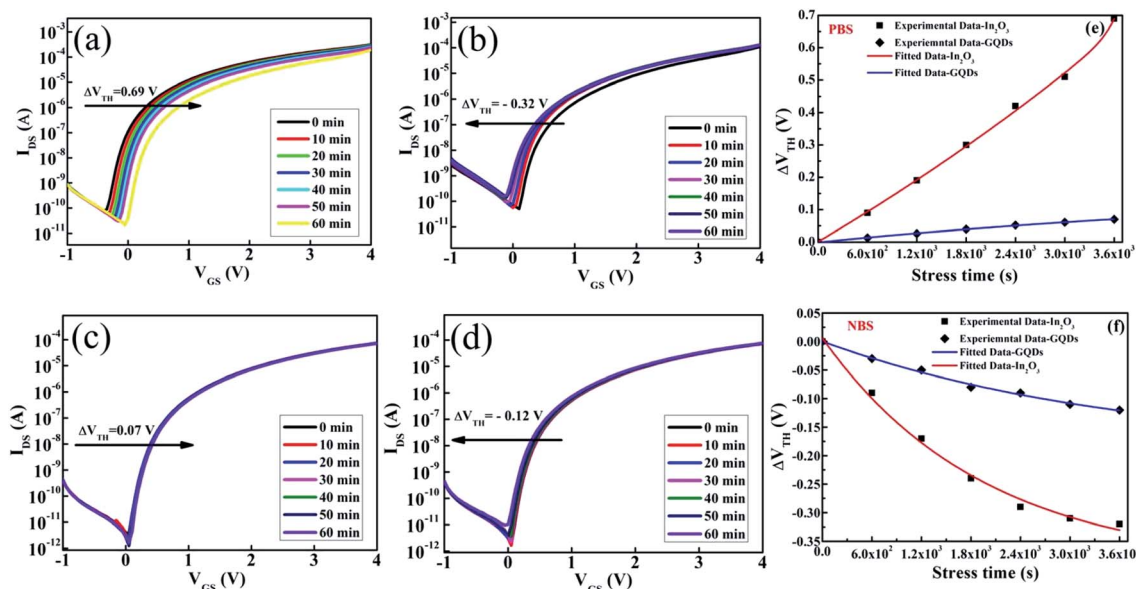

Fig. 7 Transfer curves under PBS test of (a)  $\text{In}_2\text{O}_3$  TFT and (c)  $\text{GQDs-In}_2\text{O}_3\text{-2}$  TFT. Transfer curves under NBS test of (b)  $\text{In}_2\text{O}_3$  TFT and (d)  $\text{GQDs-In}_2\text{O}_3\text{-2}$  TFT. Positive (e) and negative (f) threshold voltage shift as a function of stress time for  $\text{In}_2\text{O}_3$  TFTs and  $\text{GQDs-In}_2\text{O}_3\text{-2}$  TFTs.

PBS-induced stability with a smaller  $\Delta V_{TH}$  of 0.07 V up to 3600 s (Fig. 7(c)), indicating that appropriate GQDs doping suppressed the trapped charge in the film due to low interface states at the dielectric and channel interface, confirmed by previous  $D_{it}$  characterization. In addition, the observed parallel  $V_{TH}$  shift and negligible change in the SS value indicates that no additional defect states are created at the channel/dielectric interface under bias stressing. Fig. 7(b) and (d) present the evolution of the transfer curves of the  $\text{In}_2\text{O}_3$  and  $\text{GQDs-In}_2\text{O}_3\text{-2}$  TFTs under NBS condition. The obvious left shift of the transfer curves in NBS has been observed, which may be caused by the release of electrons from oxygen defects in the active layer under the continuous gate bias stress. Compared to pure  $\text{In}_2\text{O}_3$  TFT, the superior bias stability of the  $\text{GQDs-In}_2\text{O}_3\text{-2}$  TFT device is preserved in cases of NBS testing. The negative  $V_{TH}$  shifts after NBS application is 0.32 V for device with  $\text{In}_2\text{O}_3$  channel layer (Fig. 7(b)). Conversely, the  $\Delta V_{TH}$  value for the  $\text{GQDs-In}_2\text{O}_3\text{-2}$  TFT is reduced to  $\sim 0.12$  V (Fig. 7(d)). These results suggest that the charge trapping centers in the dielectric bulk region or  $\text{ZrO}_x/\text{In}_2\text{O}_3$  interfaces can be diminished by appropriate GQDs doping.

To confirm the dominant charge trapping mechanism causing the bias stress-induced the  $\Delta V_{TH}$  in TFTs, the relationship between the  $\Delta V_{TH}$  and the stress time has been summarized in Fig. 7(e) and (f). Results show that the time dependence of  $\Delta V_{TH}$  in the  $\text{In}_2\text{O}_3$ -based TFTs device follows a stretched exponential equation, originating from the charge being trapped at the dielectric/channel interface or getting injected into the gate dielectric. The time dependence of  $\Delta V_{TH}$  reflected by the stretched exponential model can be described as follows:

$$\Delta V_{TH} = \Delta V_{TH0} \left[ 1 - e^{-\left(\frac{t}{\tau}\right)^\beta} \right]$$

where  $t$  represents the stress time,  $\Delta V_{TH0}$  is the value of  $\Delta V_{TH}$  at infinite time,  $\tau$  is the constant characteristic trapping time of carriers, and  $\beta$  is the stretched exponential exponent, respectively. The stretched exponential model well describes the measured  $\Delta V_{TH}$ , revealing that the charge trapping is the dominant mechanism of  $\Delta V_{TH}$  at the  $\text{ZrO}_x/\text{In}_2\text{O}_3$ -based TFTs interface. Similar experiment results have been observed in our previous  $\text{InGaZnO}$ -based TFTs.<sup>59</sup>

To further explain the mechanism of  $\Delta V_{TH}$  in the transfer curves, energy band diagrams of the  $\text{GQDs-In}_2\text{O}_3$  TFTs device under PBS and NBS have been depicted in Fig. 8. When PBS measurement is performed in air atmosphere, excessive electrons will be accumulated in the  $\text{GQDs-In}_2\text{O}_3$  channel. The surrounding oxygen molecules can capture electrons (acceptor,  $\text{O}_2(\text{g}) + e^- \rightarrow \text{O}_2^-(\text{s})$ ) from the conduction band and then adsorb on the TFT device. Therefore, the  $\text{O}_2$  adsorption in the channel layer can deplete the electron carriers and the buildup of negative space charge  $\text{O}_2^-$  easily will repel conduction electrons in the  $\text{GQDs-In}_2\text{O}_3$  channel,<sup>60</sup> leading to the positive  $V_{TH}$  shift and the bending downwards of the energy band, as shown in Fig. 8(a) ( $E_f$ : Fermi energy level,  $E_c$ : conduction band,  $E_v$ : valence band,  $E_i$ : intermediate energy band). During the NBS process, the origination of NBS instability can also be attributed to the moisture absorption mechanism where this phenomenon can be expressed by the reaction equation  $\text{H}_2\text{O}(\text{g}) + h^+ \rightarrow \text{H}_2\text{O}^+(\text{s})$ .<sup>61</sup> Owing to the abundance of water molecular diffusing from the air ambient, this reaction will keep towards the right side and produce the mass of free electrons as demonstrated in Fig. 8(b), therefore the negative  $V_{TH}$  shift has been detected. Under NBS, electrons will be depleted near the interface leading the energy band bending upwards.

To investigate the compatibility of  $\text{In}_2\text{O}_3$ -based TFTs devices for circuit integration, their applications in inverter were

Fig. 8 Bias instability mechanism for GQDs- $In_2O_3$  TFT under (a) PBS and (b) NBS.

further explored because the inverters are widely considered as the fundamental element which can be fabricated based on E-mode devices. In this work, the resistance-loaded inverters are constructed based on pure  $In_2O_3$  and GQDS- $In_2O_3$ -2 TFTs and a resistor of 10 M $\Omega$  and displayed in the inset of Fig. 9(c) and (d). As demonstrated in Fig. 9(a) and (b), the typical voltage transfer characteristic (VTC) curves at certain voltages ( $V_{DD}$ ) from 0.5 to 2.5 V with 0.5 V step have been found, indicating that a full swing of inverter characteristic is resulted with the input and output signals effectively rectified. The corresponding voltage gain (defined as  $-\partial V_{OUT}/\partial V_{IN}$ ) is found to be 9.31 in maximum when  $V_{DD}$  comes up to 2.5 V (Fig. 9(c)). When replacing  $In_2O_3$  with GQDS- $In_2O_3$ -2, the inverter characteristics can be substantially enhanced with a maximum voltage gain of 10.63 under the same  $V_{DD}$ , as concluded in Fig. 9(e). Current extracted result is obviously superior to the reported inverters constructed by a single N-TFT, and even to some complementary inverters constructed by N-TFT and P-TFT.<sup>62,63</sup> The high voltage gain of

inverter benefits from high mobility, low off-state current, reliable stability and small subthreshold swing of TFT device. As reported, graphene plays an important role in the common source inverter due to its advantages such as het small transconductance, large drain conductance, and small back-gate capacitance.<sup>64</sup> Another important performance parameter, the transition width, which defines the borders of the transition region, is also extracted and show in Fig. 9(f). It can be note that compared to the  $In_2O_3$  TFT, the reduction in transition width has been observed after GQDS doping. In addition, the as-calculated maximum transition width of 0.40 V is lower than those previously reported resistor-loaded inverters based on  $In_2O_3$  (2 V) and InGaZnO (3.8 V) transistors.<sup>65,66</sup> The narrow transition width is expected to improve the responds characteristics of logic circuits.

Finally, low-frequency noise (LFN) measurements were carried out at room temperature for the pristine  $In_2O_3$  and GQDs- $In_2O_3$ -2 TFTs to investigate the reduction of the interface

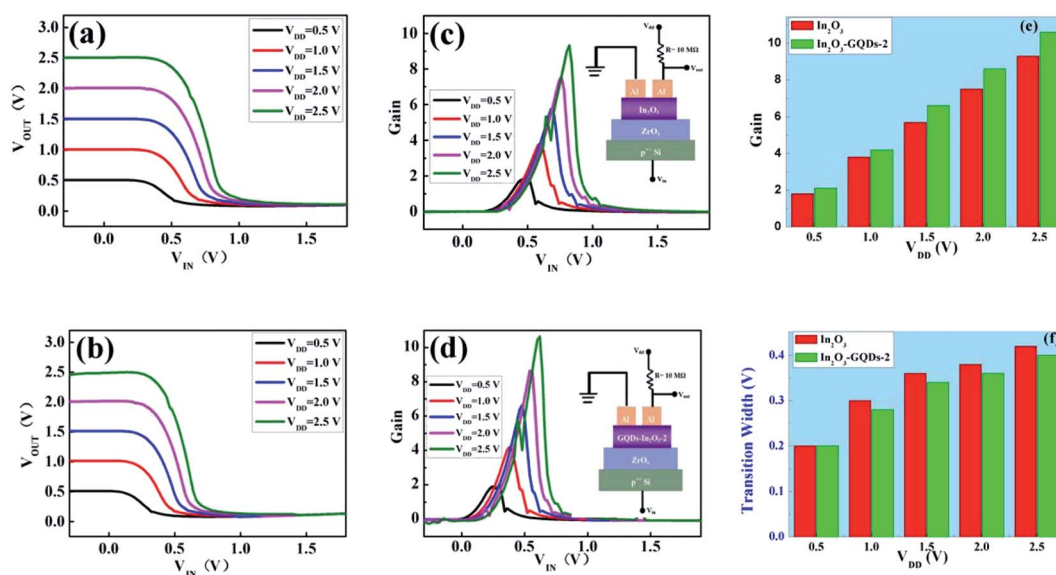

Fig. 9 VTC curves of (a)  $In_2O_3$  TFT and (b) GQDs- $In_2O_3$ -2 TFT. Voltage gain of the inverter (c)  $In_2O_3$  TFT and (d) GQDs- $In_2O_3$ -2 TFT at different applied voltages. Insets in (c) and (d) are circuit schematic of the resistor-loaded inverters. Gain (e) and transition width (f) curves of  $In_2O_3$  and GQDs- $In_2O_3$ -2 TFTs as a function of  $V_{DD}$ .

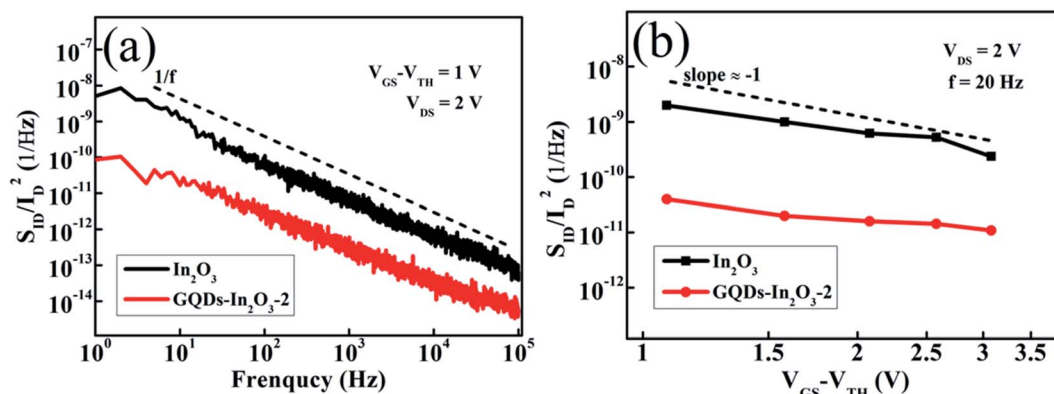

Fig. 10 (a) Typical LFN curves and (b) normalized  $S_{ID}/I_D^2$  with different bias of the  $\text{In}_2\text{O}_3$  and GQDs- $\text{In}_2\text{O}_3$ -2 TFTs.

trap density and improvement in the stability of the  $\text{In}_2\text{O}_3$  TFTs with GQDs doping with a fixed gate overdrive voltage ( $V_{GS} - V_{TH}$ ) of 1.0 V together with  $V_{DS}$  of 2.0 V, as shown in Fig. 10(a). The  $1/f$  noise curves were obtained from the linear region of the curves. Based on the experimental results, it can be noted that it is in full accord with the classical  $1/f$  noise theory.<sup>67</sup> Observably, compared with the pure  $\text{In}_2\text{O}_3$  TFT, the normalized drain current noise spectral density ( $S_{ID}/I_D^2$ ) of GQDs- $\text{In}_2\text{O}_3$ -2 TFT presents a decreasing trend, indicating that the average trap density and interface trap density for the  $\text{In}_2\text{O}_3$ -based TFT are reduced after GQDs doping. To further confirm the main source of LFN of  $\text{In}_2\text{O}_3$ -based TFTs, normalized  $S_{ID}/I_D^2$  properties were estimated and analyzed, as demonstrated in Fig. 10(b). The experimental parameters for  $S_{ID}/I_D^2$  measurement are as follows:  $V_{GS} - V_{TH} = (1-0.92)$  V,  $V_{DS} = 2$  V, and  $f = 20$  Hz. The analysis of the results shows that the slopes of the curves for the pure  $\text{In}_2\text{O}_3$  and GQDs- $\text{In}_2\text{O}_3$ -2 are close to  $-1$ , indicating that the noise source mainly results from the fluctuations in mobility.<sup>68</sup> The evolution law of the normalized drain current noise spectral density full conforms to previous electrical characterizations. As a result, it can be inferred that appropriate doping of GQDs is conducive to reducing trap density and improving the electrical properties and stability of  $\text{In}_2\text{O}_3$  TFTs.

## Conclusion

In conclusion, this work reports a novel and effective solution-based method to prepare  $\text{In}_2\text{O}_3$  TFTs with different GQDs doping amounts. Experimental results have found that GQDs- $\text{In}_2\text{O}_3$ -2 TFT has exhibited excellent electrical performance, including a large  $\mu_{FE}$  of  $34.02 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ , a high  $I_{on}/I_{off}$  of  $4.55 \times 10^7$ , a small SS of  $0.08 \text{ V dec}^{-1}$  and a small threshold voltage shift of 0.07 V and 0.12 V under PBS and NBS after 3600 s, respectively. On the basis of the GQDs- $\text{In}_2\text{O}_3$ -2 TFT, inverter with a gain of 10.63 has been successfully constructed, demonstrating full swing characteristics. LFN measurements have concluded that the noise source can come from the fluctuations in mobility. The enhanced electrical performance and reliability of  $\text{In}_2\text{O}_3$  TFTs can be ascribed to the appropriate incorporation of GQDs into the  $\text{In}_2\text{O}_3$  channel layer, leading to

the reduction of the interface trap density and oxygen vacancy states. All in all, the solution-derived GQDs-decorated oxide-based TFTs are promising for the development of transparent low-cost oxide thin film electronics.
