High performance of $\text{CH}_3\text{NH}_3\text{PbCl}_3$ perovskite single crystal photodetector with a large active area using asymmetrical Schottky interdigital contacts†

 Ji Yu,^a Jie Zheng,^a  Ning Tian,^{*a} Lin Li,^a  Yanmei Qu,^a Yongtao Huang,^a Yinxian Luo^a and Wenzhu Tan^a

Due to the limited electrode structure types of current $\text{CH}_3\text{NH}_3\text{PbCl}_3$ perovskite single crystal photodetectors, these devices either have good performance but small active area or have large active area but poor performance, which greatly limits their applications. To realize a high performance of a $\text{CH}_3\text{NH}_3\text{PbCl}_3$ perovskite single crystal photodetector with a large active area, a $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal photodetector with asymmetrical Schottky interdigital contacts originating from planar interdigital Au–Ag electrodes was fabricated in this work. The device not only had a large active area (around 8 mm^2) but also showed excellent photoelectric performance due to its built-in electric field. The responsivity of the device can reach 5.8 mA W^{-1} at 0 V and 0.24 A W^{-1} at 30 V reverse voltage. The response time of the device can reach 317 μs (rise)/6.82 ms (decay) at 0 V and 100 μs (rise)/2 ms (decay) at 30 V reverse voltage. The above results demonstrate that this study will provide an effective method for realizing high performance of a $\text{CH}_3\text{NH}_3\text{PbCl}_3$ perovskite single crystal photodetector with a large active area.

Introduction

Organic–inorganic hybrid perovskites have been considered to be promising for future optoelectronic applications due to many of their excellent properties including easy preparation, low trap-state density, high carrier mobility, large light absorption coefficient, long carrier diffusion length, and tunable direct bandgap. Significant progress has been achieved in organic–inorganic hybrid perovskite based ultraviolet (UV) photodetectors.^{1–5} For example, Thi My Huyen Nguyen *et al.* reported that a photodetector based on $(\text{FAPbI}_3)_{1-x}(\text{MAPbBr}_3)_x$ perovskite presented excellent performance with a fast response speed ($t_{\text{rise}} = 82$ ms, $t_{\text{fall}} = 64$ ms) and a high detectivity of 7.21×10^{10} Jones at zero bias under 254 nm UV illumination, along with superior mechanical flexibility at various bending angles.¹ Lian Ji *et al.* reported that a self-driven visible-blind UV photodetector based on CsPbCl_3 perovskite film showed outstanding properties with a high responsivity of 118 mA W^{-1} , a high detectivity of 6.62×10^{12} Jones, and a fast rise/fall response time of 120/820 ns.² Dali Shao *et al.* reported that $\text{Cs}_2\text{SnI}_6/\text{ZnO}$ structured UV-vis dual-band photodetector exhibited

good performance of a high detectivity in UV (1.39×10^{12} Jones), a fast response speed on the order of milliseconds.³ Thi My Huyen Nguyen *et al.* reported that a self-powered deep UV photodetector based on $(\text{FAPbI}_3)_{0.97}(\text{MAPbBr}_3)_{0.03}$ perovskite film showed a high responsivity of 52.68 mA W^{-1} , a good detectivity of 4.65×10^{11} Jones, and an outstanding on/off photocurrent ratio of more than 10^3 under 254 nm UV illumination without an external bias.⁴ Sheng Wang *et al.* reported that an UV photodetector based on BA_2PbBr_4 ($\text{BA} = \text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_3^+$) single crystal film exhibited a detectivity of $\sim 10^{12}$ Jones and a fast rise/decay response time of 9.7/8.8 ms.⁵ Among the organic–inorganic hybrid perovskites, $\text{CH}_3\text{NH}_3\text{PbCl}_3$ perovskite single crystal is regarded as an attractive candidate for UV detection due to its large direct bandgap of ~ 2.85 eV.^{6–13} At present, some progress has been made in the research of $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal photodetectors.^{8–13} For example, Hye Ri Jung *et al.* reported that an $\text{Ag}/\text{TiO}_2/\text{MAPbCl}_3/\text{TiO}_2/\text{Ag}$ structured photodetector presented a responsivity of 0.004 A W^{-1} and a detectivity of 1.05×10^{10} Jones at 430 nm under 2 V bias voltage.⁸ Jingda Zhao *et al.* reported that a n–n+ photodiodes based on $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal exhibited a responsivity of 404.7 mA W^{-1} , and a detectivity of 4.87×10^{11} Jones at 20V.⁹ Giacomo Maculan *et al.* reported that $\text{Pt}/\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal/Ti/Au vertical structured visible-blind UV-photodetector was fabricated.¹⁰ The active area of the device was about 4 mm^2 . At 15 V, the responsivity of the device was about 46.9 mA W^{-1} under illumination with 365 nm UV light. For the response speed of the device, the rise time was 24 ms and the decay time was 62 ms. Zhishuai Yuan *et al.* reported that the $\text{Pt}/\text{CH}_3\text{NH}_3\text{PbCl}_3$ single

Fig. 1 Preparation process diagram of the Au/CH₃NH₃PbCl₃ single crystal/Ag structured photodetector.

crystal/Pt metal–semiconductor–metal (MSM) structured photodetector was fabricated.¹¹ The active area of the device was 0.01 mm². At 3 V, the device showed ultra-high responsivity of 7.97 A W⁻¹, and the rise time of 1.27 ms and fall time of 1.84 ms under the illumination light of 350 nm. Zhen Cheng *et al.* reported that the Au/CH₃NH₃PbCl₃ single crystal/Au MSM structured photodetector was fabricated.¹² The active area of the device was 0.09 mm². The device showed the peak responsivity of 3.73 A W⁻¹ in the wavelength of 415 nm at 30 V and an ultrafast response speed with a rise time of 130 ns at 15 V under 365 nm pulsed laser. Yan Chen *et al.* reported that the tetragonal phase CH₃NH₃PbCl₃ single crystal photodetector with the interdigital Au electrodes was fabricated.¹³ The active area of the device was 0.2 mm². The responsivity of the device can reach 27.7 μA W⁻¹ at 3 V under 395 nm. The rise time and decay time of the device were 30 ms and 0.3 s, respectively.

Although some achievements have been made in the research of CH₃NH₃PbCl₃ single crystal photodetectors, due to the limited electrode structure types of current CH₃NH₃PbCl₃ perovskite single crystal photodetectors, these devices either have good performance but small active area or have large active area but poor performance, which greatly limits their applications. The planar asymmetrical Schottky interdigital structure is an ideal electrode structure of photodetector, which can not only ensure the large active area, but also realize the high sensitivity and fast response due to its built-in electric field.^{14–16} However, to our knowledge, there are no reports on the CH₃NH₃PbCl₃ perovskite single crystal photodetectors with asymmetrical Schottky interdigital electrodes. In this work, to realize the high performance of CH₃NH₃PbCl₃ perovskite single crystal photodetector with a large active area, a CH₃NH₃PbCl₃ single crystal photodetector with asymmetrical Schottky interdigital contacts originated from planar interdigital Au–Ag electrodes was fabricated in this work. The device not only had a large active area (around 8 mm²) but also showed excellent photoelectric performance.

Experimental

The CH₃NH₃PbCl₃ single crystals were prepared by the inverse temperature crystallization method, which has been reported in detail elsewhere.¹³ An equimolar mixture of CH₃NH₃Cl and PbCl₂ was dissolved in DMSO–DMF (1 : 1 by volume) at room

temperature to get a homogenous solution. The solution was filtered using a PTFE filter with 0.45 mm pore size. The filtrate was placed in a crystallizing dish and then was kept in an oil bath heated from 45 °C to 60 °C at the rate of 0.3 °C h⁻¹. CH₃NH₃PbCl₃ single crystals with sizes of ~1 cm were attained. The Au and Ag electrodes of the photodetector based on CH₃NH₃PbCl₃ single crystal were fabricated *via* thermal evaporation through shadow masks. Fig. 1 shows the preparation process diagram of the Au/CH₃NH₃PbCl₃ single crystal/Ag structured photodetector. Firstly, Au electrodes are evaporated on the surface of the single crystal through a comb-shaped shadow mask. Au electrodes have five fingers with the length of 4.45 mm and width of 50 μm, and the spacing of Au electrodes is 450 μm. Then, Ag electrodes are fabricated on the surface of the single crystal by the same method as Au electrodes. The parameters of Ag electrodes are the same as those of Au electrodes. Thus, planar interdigital Au–Ag electrodes are formed on the surface of the single crystal. The spacing of the Au–Ag interelectrode is about 200 μm. The active area of the device is around 8 mm², which is one of the largest active area for reported CH₃NH₃PbCl₃ single crystal photodetectors.^{8–13}

The crystal structure of the CH₃NH₃PbCl₃ single crystal and its powder was characterized by X-ray diffraction (XRD) (Rigaku-D-Max Ra system, with Cu Kα radiation operated at 12 kW). The surface morphology of the CH₃NH₃PbCl₃ single crystal was characterized by SU8220 scanning electron microscope (SEM). The absorption spectra of the CH₃NH₃PbCl₃ single crystal were determined by UV-3101PC spectrophotometer. The current–voltage (*I*–*V*) curves of the photodetector were obtained from a computerized Keithley 2400 SourceMeter. The response spectra and photocurrent–time (*I*–*t*) curves of the device were measured by a lock-in amplifier, where the light source is a Xe lamp (150 W) with a monochromator and a chopper with a frequency of 500 Hz. The response time of the device was recorded by an oscilloscope under the excitation of a 355 nm pulsed laser.

Results and discussion

To study the crystal structures of CH₃NH₃PbCl₃ single crystal and its powder, X-ray diffraction (XRD) characterization is carried out, which is shown in Fig. 2(a). Pure single phase of

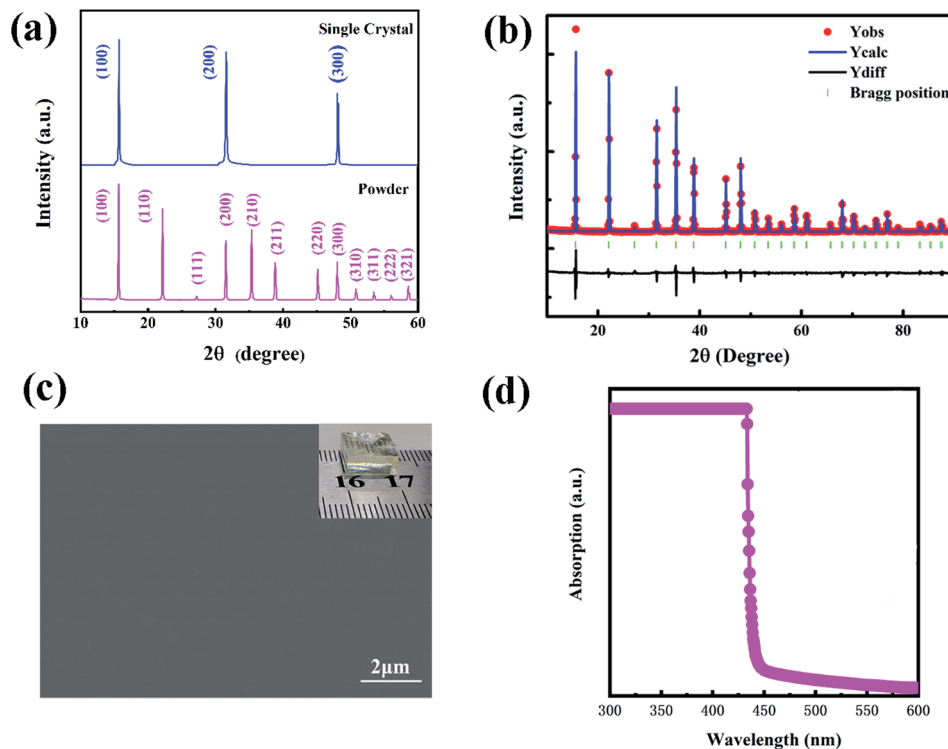

Fig. 2 (a) X-ray diffraction patterns of CH₃NH₃PbCl₃ single crystal and its powder. (b) Rietveld refinement of the powder XRD data. (c) SEM of the single crystal. Inset: photograph of the CH₃NH₃PbCl₃ single crystal. (d) Absorption spectrum of CH₃NH₃PbCl₃ single crystal.

cubic MAPbCl₃ perovskite can be noted from the XRD pattern of CH₃NH₃PbCl₃ powder obtained by grinding single crystal. Lattice constant is obtained by Rietveld refinement of the powder XRD data, which is shown in Fig. 2(b). The lattice constant is 0.5689 nm. Because the single crystal has the characteristic of preferential growth of crystal planes, only three sharp peaks corresponding to (100), (200), and (400) crystal planes can be found in the single crystal XRD pattern, which shows that the single crystal is preferably oriented in the (100) direction. The inset of Fig. 2(c) shows the photograph of the single crystal with a cuboid shape and the dimension of 10 mm × 9 mm × 4 mm. The SEM of the single crystal is shown in Fig. 2(c). It can be noted that its surface is very flat and uniform. The absorption spectrum of the single crystal is displayed in Fig. 2(d). It can be seen that the single crystal exhibits the intense absorption in the 300–435 nm wavelength region, and has a sharp absorption edge located at 435 nm. Based on this, the bandgap of the single crystal is calculated as 2.85 eV, which is suitable for UV detection.

Fig. 3(a) shows the current–voltage (*I*–*V*) curve of the Au/CH₃NH₃PbCl₃ single crystal/Ag structured photodetector measured in the dark under forward and reverse bias. Note that the reverse bias of the device refers to the Au electrode as the anode and the Ag electrode as the cathode, and the forward bias of the device refers to the Au electrode as the cathode and the Ag electrode as the anode. Obviously, the device shows the asymmetrical *I*–*V* behavior under forward and reverse bias, which is caused by the Au–Ag electrodes of the device. The *I*–*V* curve of the CH₃NH₃PbCl₃ single crystal photodetector with

symmetrical Au electrodes in dark is shown in the Fig. S1.† It can be noted that the device shows the symmetrical *I*–*V* behavior under forward and reverse bias, which is caused by the symmetrical Au electrodes of the device. Energy band diagram for the device with Au–Ag electrodes is shown in Fig. 3(b). The valence band maxima (VBM) of CH₃NH₃PbCl₃ single crystal is reported to be –5.82 eV.¹⁰ Based on its bandgap of 2.85 eV in our case, its conduction band minimum (CBM) can be calculated to be –2.97 eV. Schottky contacts are formed at the interface between the CH₃NH₃PbCl₃ single crystal and the metal electrodes. Schottky barrier heights are primarily determined by the work function of metals and the electron affinity of the CH₃NH₃PbCl₃ single crystal. A high Schottky barrier is formed at the interface of Ag (the work function of –4.26 eV)¹⁷ and the single crystal, and a low Schottky barrier is formed at the interface of Au (the work function of –5.1 eV)¹⁵ and the single crystal. So the asymmetrical Schottky interdigital contacts are generated by Au–Ag electrodes of the device, which leads to the asymmetrical *I*–*V* behavior of the device under forward and reverse bias. A built-in electric field from Au to Ag is formed in the device, which allows the device to collect photogenerated carriers without any external bias. Responsivity (*R*) of the photodetectors is calculated by the following expression:¹⁰

$$R = \frac{I_{\text{light}} - I_{\text{dark}}}{P_{\text{light}}} \quad (1)$$

The photoresponse spectrum of the device at 0 V is shown in the inset of Fig. 3(c). It can be noted that the device shows the

Fig. 3 (a) Current–voltage (I – V) curve of the device measured in dark under forward and reverse bias, with the inset showing a schematic diagram of the device structure. (b) Energy band diagram for the device. (c) Photoresponse spectra of the devices with Au–Ag electrodes at 30 V reverse bias and with symmetrical Au electrodes at 30 V. Inset: the photoresponse spectra of the above two structured devices at 0 V. (d) External quantum efficiency of the device at 30 V. Inset: detectivity of the device at 30 V. Short-term stability of the device at 0 V (e) and 30 V reverse bias (f).

maximum responsivity of 5.8 mA W^{-1} at 410 nm at 0 V. As a comparison, the spectral response of the $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal photodetector with symmetrical Au electrodes is also measured. The parameters of the symmetrical interdigital Au electrodes are same as those of the asymmetrical interdigital Au–Ag electrodes. There is almost no response for the device with symmetrical Au electrodes at 0 V. The results demonstrate that the built-in electric field is the key to realize self-powered photodetector. The photoresponse spectrum of the photodetector with Au–Ag electrodes at 30 V reverse bias is shown in Fig. 3(c). The device exhibits the broad photoresponse in the 300–420 nm wavelength region, and the cutoff wavelength of the photoresponse locates at around 420 nm, which indicates that the device is very suitable for UV detection. The responsivity of the device can reach 0.24 A W^{-1} at 415 nm, which is 7 times that of the device with symmetrical Au electrodes under the same bias. The above results indicates that the built-in electric field can improve the sensitivity of photodetector. The external quantum efficiency (EQE) of the photodetector can be determined by the following formula:^{12,18}

$$\text{EQE} = \frac{R \times hc}{e\lambda} \quad (2)$$

where R represents the responsivity of the photodetector, $h\nu$ represents the photon energy, e represents elementary charge of electron, and λ represents the wavelength of the incident light. At 30 V reverse bias, the EQE of the photodetector can reach 73% at 415 nm, which is shown in Fig. 3(d). The detectivity (D^*) of the photodetector can be calculated by the following expression:^{19,20}

$$D^* = \frac{R}{\sqrt{2qJ_d}} \quad (3)$$

where q represents the elemental charge, and J_d represents the dark current density. At 30 V reverse bias, the D^* of the photodetector can reach 1.1×10^{11} Jones at 415 nm, which is shown in the inset of Fig. 3(d). Fig. 3(e) and (f) show the short-term stability of the device at 0V and 30 V reverse bias, respectively. It can be noted that the device exhibits good repetition of photocurrent under the illumination of 350 nm, 380 nm, and 415 nm light on/off conditions respectively, which indicates the good short-term stability of the device.

Response speed is an important parameter of photodetector, which can be characterized by the transient photocurrent response. Fig. 4(a) and 4(b) show the transient photocurrent response of the device with the light source of a 355 nm pulsed

Fig. 4 Transient photocurrent response of the device with the light source of a 355 nm pulsed laser at 0 V (a) and 30 V reverse bias (b).

Table 1 Comparison of the critical parameters of the device with the reported $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal photodetectors

| Photodetector structure | R (A W^{-1}) | EQE (%) | D^* (Jones) | Response time (rise time/decay time) | Active area (mm^2) | Ref. |
|---|--------------------------------|---------------|--------------------------------|--------------------------------------|-------------------------------|-----------|
| Pt/ $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal/Ti/Au vertical structure | 0.05 (365 nm) | NA | 1.2×10^{10} (365 nm) | 24 ms/62 ms | 4 | 10 |
| Pt/ $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal/Pt MSM structure | 7.97 (350 nm) | NA | NA | 1.27 ms/1.84 ms | 0.01 | 11 |
| Au/ $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal/Au MSM structure | 3.73 (415 nm) | 1115 (415 nm) | 9.97×10^{11} (415 nm) | 130 ns/368 μs | 0.09 | 12 |
| Au/ $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal/Au planar interdigital structure | 2.77×10^{-5} (395 nm) | NA | NA | 30 ms/0.3 s | 0.2 | 13 |
| Au/ $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal/Ag planar interdigital structure | 0.24 (415 nm) | 73 (415 nm) | 1.1×10^{11} (415 nm) | 100 μs /2 ms | 8 | This work |

laser at 0 V and 30 V reverse bias, respectively. The rise and decay time is defined as the time for the photocurrent to change from 10% to 90% of its maximum value, and *vice versa*. The rise/decay times of the device at 0 V and 30 V reverse bias are 317 μs /6.82 ms and 100 μs /2 ms, respectively.

To evaluate the performance of the device, we compared the critical parameters of the device with the reported $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal photodetectors, as shown in Table 1. The R , EQE, D^* , response time, and active area of the device in this work are obviously better than those of ref. 10 and 13. The R , EQE, D^* , and response time of the device in this work are lower than those of ref. 11 and 12. However, the area of the device in this work is larger than that of ref. 11 and 12. So high performance of $\text{CH}_3\text{NH}_3\text{PbCl}_3$ perovskite single crystal photodetector with a large active area has been realized in our case.

To assess the long term stability of $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal photodetector, the performance of the Au/ $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal/Ag structured photodetector has been tested after 6 months storage in a small round sample box under ambient conditions, which is shown in the Fig. S2.† From the Fig. S2a,† it can be noted that the responsivity of $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal photodetector decreases significantly compared with that of the device six months ago. As can be seen from the Fig. S2b and S2c,† although the performance of the device has decreased, the device can still work stably.

Conclusions

In this work, a $\text{CH}_3\text{NH}_3\text{PbCl}_3$ single crystal photodetector with asymmetrical Schottky interdigital contacts originated from planar interdigital Au–Ag electrodes was fabricated. The device not only had a large active area (around 8 mm^2) but also showed excellent photoelectric performance due to its built-in electric field. The responsivity of the device can reach 5.8 mA W^{-1} at 0 V and 0.24 A W^{-1} at 30 V reverse voltage. The response time of the device can reach 317 μs (rise)/6.82 ms (decay) at 0 V and 100 μs (rise)/2 ms (decay) at 30 V. The above results indicate that high performance of $\text{CH}_3\text{NH}_3\text{PbCl}_3$ perovskite single crystal photodetector with a large active area has been realized in this work.
