Design, and synthesis of selectively anticancer 4-cyanophenyl substituted thiazol-2-ylhydrazones†

 Hasnain Mehmood,^a Mustapha Musa,^b Simon Woodward,^b Md Shahadat Hossan,^c Tracey D. Bradshaw,^c Muhammad Haroon,^a Andrew Nortcliffe^d and Tashfeen Akhtar^{id}*^a

Cyclization of substituted thiosemicarbazones with α -bromo-4-cyanoacetophenone allows rapid single-step sustainable syntheses of 4-cyanophenyl-2-hydrazinylthiazoles libraries (30 examples, 66–79%). All show anticancer efficacy against HCT-116 and MCF-7 carcinoma cell lines with the majority being more active than cisplatin positive controls. The compounds 2-(2-(2-hydroxy-3-methylbenzylidene)hydrazinyl)-4-(4-cyanophenyl)thiazole (3f) and 2-(2-((pentafluorophenyl)methylene)-hydrazinyl)-4-(4-cyanophenyl)thiazole (3a') show optimal GI₅₀ values (1.0 ± 0.1 μ M and 1.7 ± 0.3 μ M) against MCF-7 breast cancer cells. Against colorectal carcinoma HCT-116 cells, 2-(2-(3-bromothiophen-2-yl)methylene)hydrazinyl)-4-(4-cyanophenyl)thiazole (3b'), 2-(2-(2-hydroxy-3-methylbenzylidene)hydrazinyl)-4-(4-cyanophenyl)thiazole (3f), 2-(2-(2,6-dichlorobenzylidene)hydrazinyl)-4-(4-cyanophenyl)thiazole (3n) and 2-(2-(1-(4-fluorophenyl)ethylidene)hydrazinyl)-4-(4-cyanophenyl)thiazole (3w) are the most active (GI₅₀ values: 1.6 ± 0.2, 1.6 ± 0.1, 1.1 ± 0.5 and 1.5 ± 0.8 μ M respectively). Control studies with MRC-5 cells indicate appreciable selectivity towards the cancer cells targeted. Significant ($p < 0.005$) growth inhibition and cytotoxicity effects for the thiazoles 3 were corroborated by cell count and clonogenic assays using the same cancer cell lines at 5 and 10 μ M agent concentrations. Cell cycle, caspase activation and Western blot assays demonstrated that compounds 3b' and 3f induce cancer cell death via caspase-dependent apoptosis. The combination of straight forward synthesis and high activity makes the thiazoles 3 an interesting lead for further development.

1. Introduction

The attainment of affordable and sustainable cancer therapeutics is an emerging issue for both developing and other nations.^{1–3} Lead structures that can be realised in only a few synthetic steps, but still allow diverse structure–activity relationships to be defined are of high desirability in this area. Additionally, the use of only widely-available low-cost chemical building blocks from sustainable sources is also an enabling strategy. One such attractive fragment is the thiazole core (Scheme 1). Straightforward to prepare, their derivatives have already provided many disparate active lead compounds.^{4,5} The

4-substituted 2-hydrazinylthiazole species (3) are attractive, as these are easily prepared from ubiquitous thiosemicarbazones (1) and low cost α -bromoketones (2) (Scheme 1). In preliminary studies, associated with another programme,⁶ we had

Scheme 1 Accessing 2-hydrazinylthiazoles (3) and initial hit discovery.

Fig. 1 Optimal literature^{8–12} cytotoxic activities for 2-hydrazinylthiazoles (3), and one closely related compound, compared to the present work. Notes: ^atime period not given; ^bmouse model, all other cell lines are human derived.

incorporated 2-hydrazinylthiazole units into the ligand (4). To our surprise the exemplar with a 4-cyanophenyl group (alone in the series) showed very high activity against the HCT-116 human colon cancer cell line, while all others had GI_{50} values > 100 μM (Scheme 1).

The \sim 2 μM activity of the 4-cyanophenyl derivative of 4 is unusual. The anti-cancer activities of 2-hydrazinylthiazoles (3) are normally quite modest (see Fig. 1). In 2014 Secci and co-workers proposed that pharmacophores of type 3 are histone acetyltransferase (HAT) inhibitors that facilitate the onset of apoptosis in HCT-116.^{7,8}

The Secci study activities are low (only 10% apoptosis at 100 μM).^{7,8} However, in the subsequent 8 years a significant range of additional thiazole derivatives (*ca.* 80 compounds) have been prepared by various groups, the most active of which are summarised in Fig. 1.^{9–13} Although some improved activities are present in this global library, over the original Secci lead, the most active compounds are still at best only equipotent to cisplatin and related positive controls. We noticed from both thiazole and related literature that incorporation of cyano functionality onto thiazole and other heterocycles, in many cases, enhances anticancer potency.^{14–16} Although the compounds 4 suggest a clear (anti-cancer) benefit from 4-cyanophenyl inclusion within the 2-hydrazinylthiazole derivative 4, this series was synthetically problematic to work with. Therefore, as part of our ongoing research,¹⁷ we set out to synthesise a range of more simply and easily accessed 2-hydrazinylthiazole species (3), all bearing a cyanoaryl moiety at position R¹ (Scheme 1), to confirm the generality of the apparent activity effect detected.

2. Experimental

2.1. General

All reagents used in synthesis and biological evaluation were commercial (Merck, Fischer and Acros Organics) and were used as supplied. Initial thiosemicarbazones (1) are readily available either commercially and *via* simple one-step literature procedures (see ref. 17–25). Chromatographic silica gel 60 (220–240 mesh) was obtained from Merck. Thin layer chromatography was performed on foil-backed plates coated with Merck Silica gel 60 F₂₅₄. Plates were developed using ultraviolet light and basic aqueous potassium permanganate. Uncorrected melting points were measured on a DMP-300 A&E Lab apparatus. Ultraviolet (UV) absorption spectra were recorded on Shimadzu Ultraviolet-1800 spectrophotometer in the range 200–800 nm. Infrared spectra were recorded on a Bruker OPUS FT-IR spectrometer by attenuated total reflection (diamond-ATR) on solid films. Proton and ¹³C NMR spectra were recorded on Bruker DPX-400 and 500 MHz spectrometers at ambient temperatures; where necessary HSQC and HMBC techniques were used to confirm structural connectivities. Mass spectra were recorded on Bruker Micro TOF-ESI positive targeted mode. Elemental (CHN) analyses were conducted on a CE-440 Elemental Analyzer.

2.2. Synthesis of 2-(2-benzylidenehydrazinyl)-4-(4-cyanophenyl) thiazoles (3a–d')

Syntheses of (3a–d') were achieved by refluxing equimolar mixtures of the required thiosemicarbazone (1) (1.00 mmol) and α -bromo-4-cyanoacetophenone (1.00 mmol) in absolute ethanol (20 mL) for 3 to 3.5 hours. The progress of reaction was

monitored by TLC using acetone/*n*-hexane (1 : 3), if necessary, reflux times were extended to 5 h; the R_f values for individual compounds are given below. On completion the reaction mixture was allowed to cool to room temperature and poured on crushed ice (*ca.* 20 g). The precipitated solids were filtered off, washed with copious water and dried under vacuum to afford **3a–d'**. Spectral data as described below. Purity estimates are based on expected %C values from elemental analyses.

2.2.1 2-(2-(2-Fluorobenzylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3a). Off-yellow solid (69% yield), mp 230–232 °C, R_f 0.43 (acetone/*n*-hexane, 1 : 3), λ_{\max} 339 nm, IR (ATR) ν_{\max} 3257 (N–H), 3116 (C–H), 2218 (C≡N), 1606 (thiazole), 1562 (C=N), 1487, 1435, 1357, 1330 (C=C), 1053–717 (characteristic of thiazole) cm^{-1} , ^1H NMR (400 MHz, CDCl_3) δ (ppm) 8.14 (s, 1H, HC=N), 7.97–7.89 (m, 3H, ArH), 7.73 (d, $J = 8.3$ Hz, 2H, ArH), 7.41 (d, $J = 6.7$ Hz, 1H, ArH), 7.23 (app. t, $J = 7.7$ Hz, 1H, ArH), 7.12 (app. t, $J = 9.3$ Hz, 1H, ArH), 7.05 (s, 1H, thiazole-H), ^{13}C NMR (100 MHz, CDCl_3) δ 168.9 (thiazole C2), 161.4 (d, $^1J_{\text{CF}} = 216.8$ Hz, Ar_{ipso}), 146.3 (thiazole C4), 138.5 (C=N), 136.2, 132.9, 132.1, 126.7, 126.4, 124.6, 121.1 (Ar), 118.6 (CN), 116.0 (d, $^2J_{\text{CF}} = 20.9$ Hz, Ar), 112.1 (Ar_{ipso}), 106.1 (thiazole C5), not all signals could be observed due to J_{CF} couplings and low compound solubility, ^{19}F NMR (375 MHz, CDCl_3) δ –120.03, HRMS m/z 323.0757 [$\text{M} + \text{H}$] $^+$ calcd for $\text{C}_{17}\text{H}_{11}\text{FN}_4\text{S}$: 323.0766. Anal. for **3a**, as isolated, $\text{C}_{17}\text{H}_{11}\text{FN}_4\text{S}$: C, 66.34; H, 3.44; N, 17.38. Found: C, 67.39; H, 3.70; N, 17.43, corresponding to 98% purity.

2.2.2 2-(2-(3-Fluorobenzylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3b). Yellow solid (79% yield), mp 177–178 °C, R_f 0.44 (acetone/*n*-hexane, 1 : 3), λ_{\max} 337 nm, IR (ATR) ν_{\max} 3278 (N–H), 3126 (C–H) 2218 (C≡N), 1606 (thiazole), 1573 (C=N), 1487, 1415, 1355, 1257 (C=C), 1051–717 (characteristic of thiazole) cm^{-1} , ^1H NMR (400 MHz, DMSO-d_6) δ 12.38 (s, 1H, NH), 8.05 (d, $J = 2.5$ Hz, 2H, ArH), 8.02 (s, 1H, HC=N), 7.86 (d, $J = 8.5$ Hz, 2H, ArH), 7.65 (s, 1H, thiazole-H), 7.52–7.42 (m, 3H, ArH), 7.21 (app. t, $J = 9.2$, 2.5 Hz, 1H, ArH), ^{13}C NMR (100 MHz, DMSO-d_6) δ 168.9 (thiazole C2), 162.9 (d, $^1J_{\text{CF}} = 243.6$ Hz, Ar_{ipso}), 149.4 (thiazole C4), 140.6, 139.2 (C=N), 137.3 (d, $^3J_{\text{CF}} = 8.1$ Hz, Ar), 133.2, 131.3 (d, $^3J_{\text{CF}} = 8.4$ Hz, Ar), 126.6, 123.1 (d, $^4J_{\text{CF}} = 2.9$ Hz, Ar), 119.5 (CN), 116.5 (d, $^2J_{\text{CF}} = 21.6$ Hz, Ar), 112.7 (d, $^2J_{\text{CF}} = 22.7$ Hz, Ar), 110.1 (Ar_{ipso}), 108.3 (thiazole C5), ^{19}F NMR (375 MHz, DMSO-d_6) δ –112.80 (s, 1F), HRMS m/z 323.0759 [$\text{M} + \text{H}$] $^+$ calcd for $\text{C}_{17}\text{H}_{11}\text{FN}_4\text{S}$: 323.0766. Anal. for **3b**, as isolated, $\text{C}_{17}\text{H}_{11}\text{FN}_4\text{S}$: C, 63.34; H, 3.44; N, 17.38; found: C, 67.44; H, 3.59; N, 17.51%, corresponding to 95% purity.

2.2.3 2-(2-(1-(3-Bromophenyl)ethylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3c). Off-white solid (70% yield), mp 224–226 °C, R_f 0.56 (acetone/*n*-hexane, 1 : 3), λ_{\max} = 336 nm, IR (ATR) ν_{\max} 3305 (N–H), 3061, 2927 (C–H), 2223 (C≡N), 1604–1421 (thiazole), 1558 (C=N), 1479, 1342, 1280, 1261 (C=C), 1053–727 (characteristic of thiazole) cm^{-1} , ^1H NMR (400 MHz, CDCl_3) δ 7.94 (app d, $J = 5.0$ Hz, 2H, ArH), 7.91 (s, 1H, Ar–H), 7.72 (app d, $J = 4.6$ Hz, 2H, ArH), 7.69 (s, 1H, thiazole-H) 7.53 (d, $J = 7.9$ Hz, 1H, ArH), 7.31 (d, 1H, Ar–H, $J = 7.9$ Hz), 7.10 (s, 1H, ArH), 2.29 (s, 3H, CH_3), ^{13}C NMR (100 MHz, CDCl_3) δ 169.1 (thiazole C2), 149.2 (thiazole C4), 139.4 (HC=N), 138.5, 132.6, 132.1, 130.0, 129.0, 126.3, 124.5, 122.8 (Ar), 118.9 (CN), 111.1 (Ar_{ipso}), 107.2 (thiazole C5), 12.9 (CH_3), HRMS m/z 397.0117 [$\text{M} + \text{H}$] $^+$

calcd for $\text{C}_{18}\text{H}_{13}\text{BrN}_4\text{S}$ 397.0122. Anal. for **3c**, as isolated, calcd for $\text{C}_{18}\text{H}_{13}\text{BrN}_4\text{S}$: C, 54.42; H, 3.30; N, 14.10. Found: C, 54.23; H, 3.07; N, 13.92%, corresponding to >99% purity.

2.2.4 2-(2-(3-Iodobenzylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3d). Off-yellow solid (67% yield), mp 197–198 °C, R_f 0.41 (acetone/*n*-hexane, 1 : 3), λ_{\max} 341 nm, IR (ATR) ν_{\max} 3259 (N–H) overlapped by br 3600–2600 (N–HBr) 3041 (C–H), 2221 (C≡N), 1618 (thiazole), 1566 (C=N), 1494, 1415, 1359, 1265 (C=C), 1051–680 (characteristic of thiazole) cm^{-1} , ^1H NMR (500 MHz, DMSO-d_6) δ 12.36 (s, 1H, NH), 8.03 (d, $J = 8.5$ Hz, 2H, Ar–H), 8.00 (s, 1H, HC=N), 7.99 (s, 1H, ArH), 7.86 (d, $J = 8.5$ Hz, 2H, ArH), 7.72 (d, $J = 8.0$ Hz, 1H, ArH), 7.66 (d, $J = 8.0$ Hz, 1H, ArH), 7.65 (s, 1H, thiazole-H), 7.22 (app. t, $J = 8.0$ Hz, 1H, ArH), ^{13}C NMR (125 MHz, DMSO-d_6) δ 168.8 (thiazole C2), 149.3 (thiazole C4), 140.4, 139.1 (C=N), 138.2, 137.1, 134.9, 133.2, 131.4, 128.9, 126.6, 126.1 (Ar_{ipso}), 119.5 (CN), 110.1 (Ar_{ipso}), 108.3 (thiazole C5), HRMS m/z 430.9841 [$\text{M} + \text{H}$] $^+$ calcd for $\text{C}_{17}\text{H}_{11}\text{IN}_4\text{S}$: 430.9827. Anal. for **3d**·1/10HBr, as isolated, $\text{C}_{17}\text{H}_{11.1}\text{Br}_{0.1}\text{IN}_4\text{S}$: C, 46.58; H, 2.55; N, 12.78. Found: C, 46.43; H, 2.39; N, 12.74, corresponding to >99% for this salt.

2.2.5 2-(2-(1-(4-Fluorophenyl)ethylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3e). Off-yellow solid (76% yield), mp 267–269 °C, R_f 0.62 (acetone/*n*-hexane, 1 : 3), λ_{\max} 332 nm, IR (ATR) ν_{\max} 3348 (N–H), 3116, 3041 (C–H), 2220 (C≡N), 1606–1408 (thiazole), 1558 (C=N), 1508, 1346, 1280, 1213 (C=C), 1053–702 (characteristic of thiazole) cm^{-1} , ^1H NMR (400 MHz, DMSO-d_6) δ 11.35 (s, 1H, NH), 8.06 (d, $J = 8.5$ Hz, 2H, ArH), 7.87 (d, $J = 8.5$ Hz, 2H, Ar–H), 7.82 (dd, $J = 9.0$, 5.5 Hz, 2H, ArH), 7.65 (s, 1H, thiazole-H), 7.26 (app t, $J = 9.0$ Hz, 2H, ArH), 2.33 (s, 3H, CH_3), ^{13}C NMR (100 MHz, DMSO-d_6) δ 170.6 (thiazole C2), 163.0 (d, $^1J_{\text{CF}} = 246.1$ Ar_{ipso}), 149.5 (thiazole C4), 146.4, 139.4 (imine C=N), 134.8 (d, $^4J_{\text{CF}} = 2.9$ Hz, Ar), 133.2, 128.3 (d, $^3J_{\text{CF}} = 8.4$ Hz, Ar), 126.6 (Ar), 119.5 (CN), 115.9 (d, $^2J_{\text{CF}} = 21.6$ Hz, Ar), 110.0 (Ar_{ipso}), 108.5 (thiazole C5), 14.6 (CH_3), ^{19}F NMR (375 MHz, DMSO-d_6) δ –113.09, HRMS m/z 337.0922 [$\text{M} + \text{H}$] $^+$ calcd for $\text{C}_{18}\text{H}_{13}\text{FN}_4\text{S}$ 337.0923. Anal. for **3e**, as isolated, calcd for $\text{C}_{18}\text{H}_{13}\text{FN}_4\text{S}$: C, 65.27; H, 3.90; N, 16.66. Found: C, 67.67; H, 3.97; N, 16.86%, corresponding to >99% purity.

2.2.6 2-(2-(2-Hydroxy-3-methylbenzylidene) hydrazinyl)-4-(4-cyanophenyl) thiazole (3f). Light orange solid (73% yield) mp 273–275 °C; R_f 0.34 (acetone/*n*-hexane, 1 : 3), λ_{\max} 352 nm, IR (ATR) ν_{\max} 3298 (N–H), 3163 (O–H), 3165, 3041 (C–H), 2216 (C≡N), 1604–1431 (thiazole), 1573 (C=N), 1483, 1357, 1249, 1147 (C=C), 1083 (C–O), 1051–702 (characteristic of thiazole) cm^{-1} , ^1H NMR (500 MHz, DMSO-d_6) δ 12.38 (s, 1H, NH), 10.28 (s, 1H, OH), 8.30 (s, 1H, HC=N), 8.04 (d, $J = 8.5$ Hz, 2H, ArH), 7.87 (d, $J = 8.5$ Hz, 2H, ArH), 7.67 (s, 1H, thiazole-H), 7.30 (d, $J = 7.8$ Hz, 1H, ArH), 7.18 (d, $J = 7.1$ Hz, 1H, ArH), 6.85 (app t, $J = 7.5$ Hz, 1H, ArH), 2.23 (s, 3H, CH_3), ^{13}C NMR (125 MHz, DMSO-d_6) δ 167.9 (thiazole C2), 155.1 (Ar_{ipso}), 149.6 (thiazole C4), 144.9, 139.0 (C=N), 133.2, 132.4, 127.8, 126.7, 125.5, 119.9, 119.4 (Ar), 118.6 (CN), 110.3 (Ar_{ipso}), 107.7 (thiazole C5), 16.1 (CH_3), HRMS m/z 335.0958 [$\text{M} + \text{H}$] $^+$ calcd for $\text{C}_{18}\text{H}_{14}\text{N}_4\text{OS}$: 335.0966. Anal. for **3f**, as isolated, calcd for $\text{C}_{18}\text{H}_{14}\text{N}_4\text{OS}$: C, 64.65; H, 4.22; N, 16.75. Found: C, 64.18; H, 4.21; N, 16.55%, corresponding to >99% purity.

2.2.7 2-(2-(5-Chloro-2-hydroxybenzylidene) hydrazinyl)-4-(4-cyanophenyl) thiazole (3g). Off-white solid (78% yield), mp 277–278 °C, R_f 0.33 (acetone/*n*-hexane, 1 : 3), λ_{\max} 344 nm, IR (ATR) ν_{\max} 3211 (O–H), 3192 (C–H), 3109 (N–H), 2229 (C≡N), 1608 (thiazole), 1575 (C=N), 1479, 1382, 1327, 1288 (C=C), 1182 (C–O), 1056–740 (characteristic of thiazole) cm^{-1} , $^1\text{H NMR}$ (400 MHz, DMSO- d_6) δ 12.26 (br s, 1H, OH), 10.34 (br s, 1H, NH), 8.29 (s, 1H, HC=N), 8.03 (d, $J = 8.5$ Hz, 2H, ArH), 7.86 (d, $J = 8.5$ Hz, 2H, ArH), 7.63 (s, 1H, thiazole-H), 7.62 (d, $J = 2.8$ Hz, 1H, ArH), 7.24 (dd, $J = 8.7, 2.8$ Hz, 1H, ArH), 6.93 (d, $J = 8.7$ Hz, 1H, ArH), $^{13}\text{C NMR}$ (100 MHz, DMSO- d_6) δ 168.7 (thiazole C2), 155.1 (Ar_{ipso}), 149.2 (thiazole C4), 139.1 (C=N), 138.0, 133.2, 130.4, 126.6, 125.1, 123.7, 122.6 (Ar), 119.4 (CN), 118.4 (Ar), 110.1 (Ar_{ipso}), 108.0 (thiazole C5), HRMS m/z 355.0428 [$M + H$]⁺ calcd for C₁₇H₁₁ClN₄O₂S: 355.0420. Anal. for 3g·1/3H₂O, as isolated, C₁₇H_{11.66}N₄O_{1.33}S: C, 56.60; H, 3.26; N, 15.53. Found: C, 57.04; H, 2.93; N, 15.18%, corresponding to 99% purity for solvate.

2.2.8 2-(2-(5-Bromo-2-hydroxybenzylidene) hydrazinyl)-4-(4-cyanophenyl) thiazole (3h). Off-white solid (70% yield), mp 274–275 °C, R_f 0.32 (acetone/*n*-hexane, 1 : 3), λ_{\max} 352 nm, IR (ATR) ν_{\max} 3286 (br, O–H), 3115 (N–H), 3115 (C–H stretching), 2214 (C≡N), 1604 (thiazole), 1581 (C=N), 1473, 1377, 1282, 1180 (C=C), 1155 (C–O), 1053–698 (characteristic of thiazole) cm^{-1} , $^1\text{H NMR}$ (400 MHz, DMSO- d_6) δ 12.31 (s, 1H, NH), 10.38 (s, 1H, OH), 8.28 (s, 1H, HC=N), 8.04 (d, $J = 8.4$ Hz, 2H, ArH), 7.87 (d, $J = 8.4$ Hz, 2H, ArH), 7.76 (d, $J = 2.6$ Hz, 1H, ArH), 7.65 (s, 1H, thiazole-H), 7.36 (dd, $J = 8.8, 2.6$ Hz, 1H, ArH), 6.88 (d, $J = 8.8$ Hz, 1H, ArH), $^{13}\text{C NMR}$ (100 MHz, DMSO- d_6) δ 168.7 (thiazole C2), 155.5 (Ar_{ipso}), 149.4 (thiazole C4), 139.2 (C=N), 137.7, 133.2, 133.2, 127.9, 126.6, 123.2, 119.5 (Ar), 118.9 (CN), 111.3 (Ar_{ipso}), 110.1 (Ar_{ipso}), 108.1 (thiazole C5), HRMS m/z 398.9903 [$M + H$]⁺ calcd for C₁₇H₁₁BrN₄O₂S: 398.9915. Anal. for 3p, as isolated, calcd for C₁₇H₁₁BrN₄O₂S: C, 51.14; H, 2.78; N, 14.03. Found: C, 51.03; H, 2.65; N, 13.73%, corresponding to >99% purity.

2.2.9 2-(2-(2,5-Dimethylbenzylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3i). Off-yellow solid (75% yield) mp 187–188 °C, R_f 0.54 (acetone/*n*-hexane, 1 : 3), λ_{\max} 349 nm, IR (ATR) ν_{\max} 3302 (N–H), 2949 (C–H), 2233 (C≡N), 1604–1384 (thiazole), 1575 (C=N), 1481, 1348, 1271, 1204 (C=C), 1049–700 (characteristic of thiazole) cm^{-1} , $^1\text{H NMR}$ (400 MHz, CDCl₃) δ 7.97 (d, $J = 8.4$ Hz, 2H, ArH), 7.72 (s, 1H, thiazole-H), 7.69 (d, 2H, $J = 8.4$ Hz, ArH), 7.32 (s, 1H, HC=N), 7.09 (s, 1H, ArH), 7.09–7.01 (m, 2H, ArH), 2.36 (s, 3H, CH₃), 2.12 (s, 3H, CH₃), $^{13}\text{C NMR}$ (100 MHz, CDCl₃) δ 170.3 (thiazole C2), 148.9 (thiazole C4), 142.4, 138.5 (C=N), 135.7, 133.6, 132.7, 131.2, 131.0, 130.5, 127.5, 126.4 (Ar), 118.8 (CN), 111.2 (Ar_{ipso}), 106.8 (thiazole C5), 20.9 (CH₃), 19.3 (CH₃), HRMS m/z 333.1167 [$M + \text{Na}$]⁺ calcd for C₁₉H₁₆N₄S: 333.1174. Anal. for 3i, as isolated, calcd for C₁₉H₁₆N₄S: C, 68.65; H, 4.85; N, 16.85. Found: C, 68.54; H, 4.61; N, 16.69%, corresponding to >99% purity.

2.2.10 2-(2-(2,5-Dimethoxybenzylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3j). Beige solid (72% yield), mp 158–159 °C, R_f 0.52 (acetone/*n*-hexane, 1 : 3), λ_{\max} 347 nm, IR (ATR) ν_{\max} 3263 (N–H), 3109, 2953 (C–H), 3100–2600 (N–HBr salt and C–H overlapped), 2221 (C≡N), 1604–1427 (thiazole), 1564

(C=N), 1496, 1278 (C=C), 1083 (C–O), 1051–702 (characteristic of thiazole) cm^{-1} , $^1\text{H NMR}$ (400 MHz, DMSO- d_6) δ 8.34 (s, 1H, HC=N), 8.03 (d, $J = 8.4$ Hz, 2H, ArH), 7.86 (d, $J = 8.4$ Hz, 2H, ArH), 7.63 (s, 1H, thiazole-H), 7.31 (d, $J = 3.1$ Hz, 1H, ArH), 7.03 (d, $J = 9.0$ Hz, 1H, ArH), 6.96 (dd, $J = 9.0, 3.1$ Hz, 1H, ArH), 3.80 (s, 3H, OCH₃), 3.76 (s, 3H, OCH₃), $^{13}\text{C NMR}$ (100 MHz, DMSO- d_6) δ 169.0 (thiazole C2), 153.7 (Ar_{ipso}), 152.1 (Ar_{ipso}), 149.3 (thiazole C4), 139.2 (C=N), 137.4, 133.1, 126.6, 123.4 (Ar), 119.5 (CN), 116.7, 113.7, 110.0 (Ar), 109.8 (Ar_{ipso}), 108.0 (thiazole C5), 56.6 (CH₃), 55.8 (CH₃), HRMS m/z 365.1058 [$M + H$]⁺ calcd for C₁₉H₁₆N₄O₂S: 365.1072. Anal. for 3j·1/4HBr, as isolated, calcd for C₁₉H_{16.25}Br_{0.25}N₄O₂S: C, 59.33; H, 4.26; N, 14.57. Found: C, 59.54; H, 4.32; N, 14.16%, corresponding to >99% purity for this salt.

2.2.11 2-(2-(4-Methoxy-2-methylbenzylidene) hydrazinyl)-4-(4-cyanophenyl) thiazole (3k). Beige solid (65% yield), mp 240–242 °C, R_f 0.51 (acetone/*n*-hexane, 1 : 3), λ_{\max} 343 nm, IR (ATR) ν_{\max} 3269 (N–H), 3120, 2918 (C–H), 2223 (C≡N), 1606 (thiazole), 1566 (C=N), 1504, 1448, 1411, 1359 (C=C), 1170 (C–O), 1051–709 (characteristic of thiazole vibrations), $^1\text{H NMR}$ (500 MHz, DMSO- d_6) δ 12.04 (s, 1H, NH), 8.23 (s, 1H, HC=N), 8.03 (d, $J = 8.6$ Hz, 2H, ArH), 7.86 (d, $J = 8.6$ Hz, 2H, ArH), 7.64 (d, $J = 8.5$ Hz, 1H, ArH), 7.59 (s, 1H, thiazole-H), 6.88–6.80 (m, 2H, ArH), 3.78 (s, 3H, OCH₃), 2.43 (s, 3H, CH₃), $^{13}\text{C NMR}$ (125 MHz, DMSO- d_6) δ 169.2 (thiazole C2), 160.3 (Ar_{ipso}), 149.3 (thiazole C4), 141.6, 139.3 (C=N), 138.4, 133.1, 128.5, 126.6, 125.4, 119.4 (CN), 116.5 (Ar), 112.6 (Ar_{ipso}), 109.9 (Ar), 107.7 (thiazole C5), 55.6 (OCH₃), 20.4 (CH₃), HRMS m/z 349.1119 [$M + H$]⁺ calcd for C₁₉H₁₆N₄O₂S: 349.1123. Anal. for 3k, as isolated, calcd for C₁₉H₁₆N₄O₂S: C, 65.50; H, 4.63; N, 16.08. Found: C, 65.51; H, 4.56; N, 16.14%, corresponding to >99% purity.

2.2.12 2-(2-(2,4-Dimethoxybenzylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3l). Brick red solid (71% yield), mp 237–238 °C, R_f 0.53 (acetone/*n*-hexane, 1 : 3), λ_{\max} 345 nm, IR (ATR) ν_{\max} 3277 (N–H), 2972 (C–H), 2223 (C≡N), 1598 (thiazole), 1568 (C=N), 1471, 1452, 1354, 1276 (C=C), 1168 (C–O), 1051–707 (characteristic of thiazole) cm^{-1} , $^1\text{H NMR}$ (500 MHz, DMSO- d_6) δ 12.03 (s, 1H, NH), 8.29 (s, 1H, HC=N), 8.03 (d, $J = 8.6$ Hz, 2H, ArH), 7.86 (d, $J = 8.6$ Hz, 2H, ArH), 7.71 (d, $J = 9.3$ Hz, 1H, ArH), 7.59 (s, 1H, thiazole-H), 6.65–6.60 (m, 2H, ArH), 3.85 (s, 3H, OCH₃), 3.82 (s, 3H, OCH₃), $^{13}\text{C NMR}$ (125 MHz, DMSO- d_6) δ 169.1 (thiazole C2), 162.4 (Ar_{ipso}), 158.9 (Ar_{ipso}), 149.3 (thiazole C4), 139.3 (C=N), 137.9, 133.1, 126.6, 126.5 (Ar), 119.5 (CN), 115.6, 109.9 (Ar_{ipso}), 107.6 (thiazole C5), 106.9 (Ar), 98.7 (Ar), 56.2 (CH₃), 55.9 (CH₃), HRMS m/z 365.1062, [$M + \text{Na}$]⁺ calcd for C₁₉H₁₆N₄O₂S: 365.1072. Anal. for 3l, as isolated, calcd for C₁₉H₁₆N₄O₂S: C, 62.62; H, 4.43; N, 15.37. Found: C, 62.27; H, 4.29; N, 15.09%, corresponding to >99% purity.

2.2.13 2-(2-(2,4-Bis(trifluoromethyl) benzylidene) hydrazinyl)-4-(4-cyanophenyl) thiazole (3m). Off-yellow solid (66% yield), mp 253–255 °C, R_f 0.55 (acetone/*n*-hexane, 1 : 3), λ_{\max} 335 nm, IR (ATR) ν_{\max} 3317 (N–H), 3101 (C–H), 2218 (C≡N), 1504 (thiazole), 1562 (C=N), 1344, 1269 (C=C), 1083–742 (characteristic of thiazole) cm^{-1} , $^1\text{H NMR}$ (400 MHz, DMSO- d_6) δ 12.78 (s, 1H, NH), 8.37 (d, $J = 2.3$ Hz, 1H, HC=N), 8.29 (d, 1H, $J = 8.5$ Hz, ArH), 8.09 (d, $J = 8.5$ Hz, 1H, ArH), 8.03 (s, 1H, ArH), 8.01 (d, $J = 8.5$ Hz, 2H, ArH), 7.85 (d, $J = 8.5$ Hz, 2H, Ar–H),

7.72 (s, 1H, thiazole-H), ^{13}C NMR (100 MHz, DMSO- d_6) δ 168.2 (thiazole C2), 149.4 (thiazole C4), 138.9 (C=N), 136.7, 135.2, 133.2, 132.8, 130.0, 128.8, 127.7, 126.6, 125.2 (Ar_{ipso}), 123.6, 122.5, 119.4 (CN), 110.2 (Ar_{ipso}), 109.1 (thiazole C5); not all signals could be observed due to multiple J_{CF} couplings and low compound solubility, ^{19}F NMR (375 MHz, DMSO- d_6) δ -57.77 (s, 3F), -61.44 (s, 3F), HRMS m/z 441.0606 [M + H]⁺ calcd for C₁₉H₁₀F₆N₄S 441.0608. Anal. for **3h**·1/2EtOH, as isolated, calcd for C_{20.33}H₁₄F₆Cl₂N₄O_{0.66}S: C, 51.84; H, 2.83; N, 12.09. Found: C, 51.60; H, 2.00; N, 11.46%, corresponding to >99% purity for this solvate. The residual solvent was easily removed under prolonged drying.

2.2.14 2-(2-(2,6-Dichlorobenzylidene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3n). Off yellow solid (68% yield), mp 250–251 °C, R_f 0.45 (acetone/*n*-hexane, 1 : 3), λ_{max} 331 nm, IR (ATR) ν_{max} 3278 (N–H), 3115 (C–H), 2216 (C≡N), 1604–1408 (thiazole), 1581 (C=N), 1562, 1483, 1433, 1361 (C=C), 1051–705 (characteristic of thiazole) cm^{-1} , ^1H NMR (400 MHz, DMSO- d_6) δ 12.53 (s, 1H, NH), 8.29 (s, 1H, HC=N), 8.03 (d, J = 8.5 Hz, 2H, ArH), 7.87 (d, J = 8.5 Hz, 2H, ArH), 7.65 (s, 1H, thiazole-H), 7.55 (d, J = 8.2 Hz, 2H, ArH), 7.39 (app. t, J = 7.5 Hz, 1H, ArH), ^{13}C NMR (100 MHz, DMSO- d_6) δ 168.8 (thiazole C2), 149.4 (thiazole C4), 139.1 (C=N), 136.8 (Ar), 134.0 (Ar_{ipso}), 133.2, 130.9, 130.0, 129.9, 126.6 (Ar), 119.5 (CN), 110.1 (Ar_{ipso}), 108.6 (thiazole C5), HRMS m/z 373.0072 [M + Na]⁺ calcd for C₁₇H₁₀Cl₂N₄S 373.0081, Anal. for **3n**, as isolated, calcd for C₁₇H₁₀Cl₂N₄S: C, 54.70; H, 2.70; N, 15.01. 388.953 [M + H]⁺ calcd for C₁₅H₉BrN₄S₂: 388.9530. Anal. for 3c', as isolated, C₁₅H₉BrN₄S₂: C, 46.28; H, 2.33; N, 14.39. Found: C, 46.16; H, 2.22; N, 14.13, corresponding to >99% purity.

2.2.30 2-(2-((4,5-Dimethylthiazol-2-yl)methylene)hydrazinyl)-4-(4-cyanophenyl) thiazole (3d). Turmeric yellow solid (69% yield), mp 262–263 °C, *R_f* 0.37 (acetone/*n*-hexane, 1 : 3), λ_{max} 367 nm, IR (ATR) ν_{max} 3174 (N–H), 3070, 2920 (C–H), 2223 (C≡N), 1606–1433 (thiazole), 1577 (C=N), 1471, 1346, 1278, 1251 (C=C), 1055–738 (characteristic of thiazole) cm⁻¹, ¹H NMR (400 MHz, DMSO-*d*₆): δ 12.50 (s, 1H, NH), 8.08 (s, 1H, HC=N), 8.01 (d, *J* = 8.4 Hz, 2H, ArH), 7.85 (d, *J* = 8.4 Hz, 2H, ArH), 7.64 (s, 1H, thiazole-H), 2.35 (s, 3H, CH₃), 2.25 (s, 3H, CH₃), ¹³C NMR (100 MHz, DMSO-*d*₆) δ 149.7 (thiazole C4), 136.8 (HC=N), 133.2, 130.0, 128.3, 126.6 (Ar), 119.4 (CN), 108.7 (thiazole C5), 14.9 (thiazole, C4–CH₃), 11.7 (thiazole, C5–CH₃), not all signals could be observed due to low compound solubility, HRMS *m/z* 340.0684 [M + H]⁺ calcd for C₁₆H₁₃N₅S₂: 340.0690. Anal. 3d'·1/6EtOH, as isolated, calcd for C_{16.33}H₁₄N₅O_{0.17}S₂: C, 56.52; H, 4.07; N, 20.18. Found: C, 56.17; H, 3.71; N, 20.18%, corresponding to >99% purity for this solvate. The residual solvent could be removed only under prolonged drying.

2.3. Biological methods

2.3.1 Cell culture. The carcinoma cell lines used in anti-cancer biological experiments were from the American Type Tissue Cell Culture Collection (ATCC), cultivated in nutritional medium (RPMI 1640) supplemented with 10% (v/v) fetal bovine serum and 1% (v/v) glutamine. Cell lines were passaged twice weekly and cultured at 37 °C in a 5% CO₂ maintained incubator to maintain logarithmic growth. To decrease genotypic/phenotypic drift, ≤30 passaged cells used in the experiments. All compounds were dried prior to biological screening. Milligram quantities of cisplatin and compounds 3a–d' were weighed using an ultra-micro balance (accurate to ±0.02 mg). Fresh stock solutions (10 mM) of trialled compounds and cisplatin controls were prepared in DMSO for each experiment, and all experiments were performed in triplicate. Colon cancer cell line (HCT-116), breast cancer cell line (MCF-7) and non-carcinogenic MRC-5 fibroblasts were used in the investigation.

2.3.2 MTT cell viability assay. MTT assays were used to evaluate the cell viability of HCT-116, MRC-5, and MCF7 cells, as described by Mosmann in 1983.²⁶ In 96 well plates cells were seeded (180 μL per well). To allow exponential growth, cells were seeded at 3 × 10³ cells per well and incubated for 24 h at 37 °C/5% CO₂ prior to test agent introduction. From the stock solution, serial dilutions were made in nutrient medium to achieve final concentrations of 0.05 μM, 0.1 μM, 0.5 μM, 1 μM, 5 μM, 10 μM, 20 μM, and 50 μM, respectively. The T0 plate was read at the time of test agent addition, and the other plates after 72 h exposure to test agents. All plates were incubated for another 2.5 h following addition of 50 μL MTT solution (5 mg mL⁻¹ PBS). The supernatant was removed from each well, and 150 μL DMSO was added. Depending on the number of viable cells, a colour change of varying intensity (purple colour) was detected. At a wavelength of 550 nm, absorbance was measured with

a 2104 EnVision® multilabel plate reader. GI_{50} values (concentration required to achieve 50% growth inhibition) were calculated by interpolation, using standard procedures as detailed previously.⁶

2.3.3 Cell counts. While MTT assay is commonly used to assess cell viability and proliferation there are several drawbacks to this approach, such as false positive results caused by chemicals that may reduce the MTT (irrespective of any cellular process). Therefore a cell count test was used to confirm our MTT results. Cells were harvested and counted in the same way as for the MTT experiment, seeded at a density of 2×10^4 in 6-well plates. After being treated with test compounds at concentrations of 5 and 10 μM , the cells were grown for 72 h. A haemocytometer was used to count the cells.

2.3.4 Clonogenic assay. Clonogenic assays were carried out by seeding 400 cells per well in 6-well plates with 2 mL medium and allowing them to attach for 24 h. A haemocytometer was used to count the cells. Cells were treated with **3** at 5 and 10 μM concentrations, as guided by the initial MTT studies. The medium alone was used as a control. After 24 h of compound exposure, the medium was aspirated and washed with 1 mL of cold PBS. Fresh medium (2 mL) was added, and the cells were incubated at 37 °C. Daily inspection was conducted until colonies of ≥ 50 cells established in the control wells. Colonies were washed in PBS before being fixed in 100 percent methanol (0.5 mL) for 15 minutes. Finally, 0.7 mL of 0.05 percent methylene blue was used for staining (water : methanol 1 : 1). The number of cell colonies were counted.

2.3.5 Cell cycle assay. Cell cycle analyses were performed by the method reported by Nicoletti.²⁷ In a 10 cm Petri dishes cells were seeded with 10 mL medium, density of 7×10^5 (control, 24 h) and 4×10^5 (48 and 72 h) cells per dish. After 24 h incubation at 37 °C cells were treated with desired concentrations of the synthesized compounds (5 and 10 μM). The medium and flocculent cells were transferred to a 15 mL Falcon tube after treatment period. The harvesting of cells was achieved by adding 0.5 mL of $1 \times$ trypsin EDTA solution. After cells had detached, they were added to the falcon tube and content were centrifuged at 1200 rpm for 5 min at 4 °C in a Beckman Coulter Allegro 33. Supernatant was removed and pellet was broken down ensuing 1 mL PBS addition and the tubes were vortexed and centrifuged twice and the cells were suspended in 0.7 mL cold hypotonic fluorochrome solution. In a labelled (FACS) fluorescence activated cell sorter tube cells were transferred and stored overnight at 4 °C in dark. To attain single cell suspensions the cells were vortexed. A total of 10 000 events were recorded for each sample which were counted using a FC500 Beckman Coulter flow cytometer and the results were analysed by using WEASEL.⁶

2.3.6 Caspase-3/7 activity assay. Caspase-3/7 activity was determined by Apo-ONE® homogeneous caspase-3/7 assay (Promega).⁶ In 96 well opaque white cell culture plates, 3×10^3 per well cells were seeded and incubated at 37 °C for 24 h followed by addition of compounds **3b'** and **3f** (*i.e.* 5 and 10 μM for 72 h exposure). Apo-ONE® caspase-3/7 reagent was added to each well, gently mixed at 300–500 rpm for 30 seconds followed by incubation for 30 min at room temperature. The EnVision

multilabel plate reader (PerkinElmer) was used to measure the well fluorescence at wavelengths between 499 nm and 521 nm.

2.3.7 Western blot assay. Western blotting was carried out using method reported.²⁸ Suitable 10 cm² dishes cells were seeded at a density of $1-2 \times 10^6$ per dish and allowed to attach for 24 h prior to exposure to 5 μM and 10 μM test compounds. Cell lysates were prepared after the desired treatment period, protein concentrations were determined using the Bradford assay.²⁹ SDS PAGE was used to separate the proteins (50 μg each sample) which were then transferred to a nitrocellulose membrane. Primary antibodies to PARP-1, and GAPDH were from Promega UK. Immunoblotting was used to detect the proteins, as previously described.³⁰ ImageJ software was used for densitometric analyses.

3. Results and discussion

3.1. Synthesis of 4-substituted 2-hydrazinylthiazole species (3)

A library of 30 compounds was prepared using α -bromo-4-cyanoacetophenone (**2**, $R^1 = 4\text{-C}_6\text{H}_4\text{CN}$ in all cases) from a range of readily available thiosemicarbazones (**1a-d'**).¹⁷⁻²⁵ Reflux of the reaction components in ethanol for 3–3.5 h afforded modest to good yields of **3a-d'** (Table 1) all of which could be isolated by simple filtration of directly precipitated products.

Across the library of 30 thiazoles (**3a-d'**) the average purity was 98% with a standard deviation of 2%, based on elemental analysis data. Combustion analyses also revealed that traces of water/EtOH or low levels of product protonation by the HBr reaction by-products that fully accounted for the minor impurities. The HBr/H₂O impurities can be seen by IR (where they cause a shallow broad νOH feature to develop 3600–2500 cm^{-1} due to extensive hydrogen bonding) but are best detected particularly by CHN combustion analysis. They are not easily quantified by NMR. All compounds **3** were of the desired formulation, except for **3u**, where the hemi-HBr salt was the major product on the basis of combustion analysis. The latter compound was not further purified due to its low biological activity in preliminary studies (GI_{50} value $12.8 \pm 0.7 \mu\text{M}$ and $27.2 \pm 0.5 \mu\text{M}$ against MCF-7 and HCT-116 carcinoma cell lines, see later). It proved challenging to obtain accurate CHN combustion data on fluorine-containing compounds **3r**, **3t** and **3w**, and this may reflect their resistance to combustion. The data presented represents the lower limit on their purity, which is still >95%. Issues associated with attaining high accuracy CHN analyses of F-containing organic compounds are well known.³¹ All compounds were extensively dried before use in biological assay.

Multinuclear NMR studies are also in line with isolated **3** analogues having purities of 95–98% and confirm that proposed connectivity has been isolated. The observation of appropriate HRMS $[\text{M} + \text{H}]^+$ also support the isolation of the desired targets. In all cases the presence of an azomethine linkage is confirmed by a ¹³C NMR signal in the range of 138.5–147.7 ppm. The presence of the hydrazone is evidenced by the presence of characteristic amine (3348–3174 cm^{-1}) and imine

(1629–1408 cm⁻¹) stretches in the solid state IR spectra. In the latter case the band is sometimes overlapped by thiazole skeletal vibrations. ¹³C NMR spectroscopy is diagnostic of the substitution pattern in the thiazole: C2 appears in the range 167.8–170.6 ppm, C4 at 149.3–155.2 ppm while C5 appears at 105.3–109.9 ppm. Although well suited to aqueous biological studies at millimolar and lower concentrations, compounds **3** are poorly soluble in many organic solvents. Fully assigned ¹³C NMR spectra could be attained in most cases, but those **3** containing extensively fluorine-coupled carbons proved problematic, even for long spectral accumulation times. The ¹H NMR spectra of **3a–d'** are unremarkable, but indicate the presence of the connectivity proposed in Table 1. By performing our analyses in DMSO-d₆ we could slow NH exchange allowing this to also be observed at *ca.* 12.5 ppm. The studies proved that compounds with similar core exist in *trans* form,^{32,33} hence synthesized compounds should also exist in *trans* configuration.

3.2. Biological evaluation

3.2.1 MTT assayed anti-cancer activity. The growth inhibitory potential of **3a–d'** against the HCT-116 and MCF-7 cancer cell lines was determined by MTT assays. Potential growth inhibitory selectivity for carcinoma cell lines over normal cells was also probed using MRC-5 fibroblasts. Results of MTT assays were corroborated by cell count assays. Further, clonogenic assays were performed to determine cancer cell survival and retention of proliferative capacity after a brief challenge with test agent. The effects of the agents **3** on cell cycle perturbation and interrogation of apoptotic cell death were examined by flow cytometry, caspase activation and western blot assays. Growth inhibitory potential of **3a–d'** was compared with cisplatin as a positive control (Table 2). Using standard MTT methods,⁶ GI₅₀ values (the concentration of test agent that inhibits cell growth by 50%) were calculated. The selectivity of compounds **3** towards cancer cell lines was determined by comparing their activity against normal human lung fibroblast (MRC-5) cells. Consequently, selectivity indices (SIs) were calculated for both cisplatin and the tested compounds **3**.

3.2.2 Effect of substituent R³ on the anti-cancer activity of **3 (SAR).** Pleasingly from the array of compounds prepared, the majority of compounds were highly active in both cancer cell lines tested (Table 1 and Fig. 2). In fact, the majority of compound series **3** analogues are more active than the cisplatin positive control as cisplatin GI₅₀ values of 7.5 ± 0.7 and 9.8 ± 0.2 μM against MCF-7 and HCT-116 cells respectively were recorded. The GI₅₀ value of 9.7 μM against MRC-5 fibroblasts demonstrates the limited therapeutic window of cisplatin; cisplatin exhibited poor SIs of 0.9 and 1.3 for HCT-116 and MCF-7 respectively. The results (Table 2) indicated that only two compounds (**3w** and **3o**) have appreciably greater activity against the MRC-5 cell line when compared with MCF-7 and HCT-116. Most other compounds are more selective towards carcinoma cell lines (**3i** is marginal). Compound **3f** substituted with 2-hydroxy-3-methyl functionality was the most potent dual growth inhibitor from the library with GI₅₀ values of 1.0 ± 0.1

Table 2 Activity of 2-(2-benzylidenehydrazinyl)-4-(4-cyanophenyl) thiazole (**3a–d'**) against MCF-7 and HCT-116 cancer cell lines and normal MRC-5 fibroblasts, as determined by MTT *in vitro* studies^{a,b} and SAR analysis^{c,d}

μM and 1.6 ± 0.1 μM against MCF-7 and HCT-116 cells respectively, and due to its low molecular weight led to satisfactory ligand efficiency values for both cell lines. Compound **3f** also demonstrated good selectivity with SI > 10 over MRC-5 fibroblasts. The *c* log *P* for this compound was calculated as 3.85, indicating the potential for good oral bioavailability.^{34,35} Pentafluorosubstituted compound **3a'** shows comparable potency to **3f** against MCF-7 cells but with increased lipophilicity and maintaining a MRC-5 SI of 6.8. Compound **3m** bearing two trifluoromethyl groups at positions 2 and 4 is also a potent growth inhibitor with GI₅₀ 2.0 ± 0.8 μM but with unfavourable lipophilicity. Compound **3n** (R³ = 2,6-Cl₂C₆H₃) was most active against HCT-116 showing a GI₅₀ value 1.1 ± 0.5

μM but with a calculated lipophilicity value of 4.97, compound **3n** presents a less favourable lead than **3f** against HCT-116 cells with a comparable MRC-5 SI. An interesting trend can be observed in the 3-halogen substituted compounds **3b–d**. An inverse relationship to size can be seen for potency against MCF-7 and HCT-116 cells. 3-Fluorosubstituted compound **3b** shows poor activity against MCF-7 cells (36.6 μM) but highly potent against HCT-116 cells at 2.2 μM. Inversely, 3-iodosubstituted compound **3d** shows good potency against MCF-7 cells (GI₅₀ 2.3 μM); but a 5-fold reduction in potency against HCT-116 cells, indicating that the size of the substituent in the *meta*-position has an influence on activity and that smaller substituents in this position may negatively impact MCF-7 potency.

Fig. 2 Correlation plot between MCF-7 and HCT-116 GI₅₀ values. Cisplatin control shown in orange.

Fluorine substitution in the *para*-position was equally poorly active against MCF-7 cells with a 3-fold decrease in activity against HCT-116 cells. Compounds **3b'**–**d'** replace the aryl ring with heterocyclic isosteres. Compound **3b'** demonstrates good anti-cancer potency against both cancer cell lines with SI values of 5.0 and 12.2 respectively. 2-Bromothiophene compound **3c'** shows comparable potency to **3b'** against MCF-7 cells but shows comparable cytotoxicity resulting in a poor selective index. The 3-bromothiophene containing compound **3d'** displays modest growth inhibition against HCT-116 cells, with an improved SI of 5.1. Considering the methoxy substituted compounds **3j**, **3l**, **3o**, **3y** and **3z** respectively it can be seen that the substitution pattern of the aromatic ring has a significant effect on the potency of the compound. For example, the introduction of a 4-position methoxy group to compound **3o** to yield **3y** increases the activity against MCF-7 and HCT-116 cells decreasing GI₅₀ values from $47.8 \pm 1.1 \mu\text{M}$ and $35.6 \pm 1.1 \mu\text{M}$ to 2.7 ± 0.1 and $1.6 \mu\text{M}$ respectively. The same methoxy addition to compound **3j** provides **3z** which benefits from a 3.5-fold increase in activity against HCT-116 cells with no significant change in activity against fibroblasts, resulting in an improved SI from 3.3 to 11.5. Interestingly, 2,4-methoxy substituted compound **3l** shows reduced potency against both cancer cell lines along with no significant activity against MRC-5. However, the need to add additional methoxy groups to improve the selectivity results in decreased ligand efficiency for these compounds. The use of electron-donating methoxy groups reduces fibroblast toxicity compared to other electron donating groups. Compounds **3i** and **3j** have similar overall molar refractivity $102.8 \text{ cm}^3 \text{ mol}^{-1}$ and $105.5 \text{ cm}^3 \text{ mol}^{-1}$ respectively; with comparable anticancer activity – but significantly different activity toward MRC-5 cells. Substitution with additional methoxy groups results in decreased lipophilicity in compounds **3y** and **3z** showing good drug-like properties commensurate with oral bioavailability in line with compliance to Lipinski and Veber guidelines with modest ligand efficiency improved lipophilic efficient than **3f**.^{35–37} Clearly, substitution on the aromatic ring in the R³ position can strongly influence the overall activity of these

compounds; however, a wider scope library would be needed to fully investigate the nuances of the structure–activity relationships. As the electronic effects of substituents are not correlated to electron withdrawing or donating substituents as can be seen with the comparable potencies of **3a'** (pentafluoro) and **3y** (3,4,5-methoxy) in both cell lines.

3.2.3 Cell count studies. To corroborate MTT studies, compounds with potent *in vitro* anticancer activity (**3f**, **3m**, **3n**, **3a'** and **3b'**) were selected for cell count experiments (Fig. 3).

These investigations show compound **3n** (R³ = 2,6-dichlorophenyl) inhibited HCT-116 growth significantly, (50–55% of the untreated control sample at 5 μM and 100% at 10 μM). Additionally, **3b'** (R³ = 3-bromothiophene) exhibited 50–55% inhibition at 5 μM and 90–95% at 10 μM against HCT-116. Compound **3f** (R³ = 2-hydroxy-3-methylphenyl) inhibited MCF-7 by 100% at 10 μM and 55–60% at 5 μM . At a concentration of 10 μM , compounds **3a'** (R³ = 1,2,3,4,5-pentafluorophenyl) exhibited 90–95% growth inhibition and **3h** (R³ = 2,4-bis(trifluoromethyl)phenyl) showed 65–70% inhibitory potential.

3.2.4 Clonogenic assays. The ability of single cells (HCT 116 and MCF-7) to survive brief challenge (24 h) by **3** and survive to produce progeny colonies was determined by clonogenic assay. Selected **3** analogues were interrogated at 5 and 10 μM . Fig. 4 shows results of clonogenic assays. The number of colonies formed after brief exposure to test agents are represented as survival fractions (in % values) of control colony numbers. After 24 h treatment compounds **3** strongly suppressed cell colony formation at 5 and 10 μM concentrations. Compounds **3a**, **3b**, **3f**, **3n**, **3v**, **3w**, **3z**, **3a'** and **3b'** are presented in Fig. 3A, all

Fig. 3 Cell count assay for selected compounds against MCF-7 and HCT-116 cells. Cells were seeded at a density of 2×10^4 per well; counts were performed following 72 h exposure to test agent. Data represented as % control, mean \pm SD for 2 independent experiments performed in triplicate. Significance is reported as * $p < 0.01$, ** $p < 0.004$, * $p < 0.02$, ** $p < 0.006$, * $p < 0.01$ and * $p < 0.02$ compared to control. The compounds screened and the concentrations used are shown on the x-axis.

Fig. 4 Effect of selected compounds on (A) HCT-116 and (B) MCF-7, colony formation. Bar graphs (A and B) both show the mean survival fraction of % control represented of mean \pm SD of five independent trials ($n = 2$ per trial). Significance is reported as * $p < 0.05$, ** $p < 0.005$ compared to control.

compounds prevent (100%) colony formation at 10 μM concentration. At 5 μM between 5 and 50% inhibition of colony formation is seen. Fig. 3 also demonstrates compounds 3 suppress HCT-116 colony formation. Compound 3f was the most effective, completely inhibiting colony formation at both 5 and 10 μM . At 10 μM compounds 3a, 3q, 3t, 3a' and 3b' completely prevented colony formation while at 5 μM only 5–30% inhibition was observed.

3.2.5 Cell cycle analysis. To shed light on the mechanism of action of this class of compound, 3f was investigated as a representative example in the cell-cycle assay. After 24 h treatment of HCT-116 and MCF-7 with compound 3f (5 and 10 μM) both cell lines showed increases in the portion of cells in the G2/M phase (Fig. 5). The observed G2/M arrest indicates DNA damage and cell cycle checkpoint attempts to initiate repair. Pre-G1 events (5–8%) were detected in HCT-116 populations exposed to 3f, an indication of caspase-excision of DNA characteristic of apoptosis. Consistent with this the MCF-7 cell line showed negligible pre-G1 cell populations; MCF-7 cells lack the caspase 3 proteases responsible for DNA excision and protein cleavage.²⁷ Here the G2/M (MCF-7) cell accumulation

also indicates DNA damage and attempt at repair. For HCT-116 the highest accumulation of cells in the G2/M phase at 5 and 10 μM concentrations was 22% and 26% compared to control (14%). The G2/M phase arrest is somewhat more obvious in MCF-7 cells, with the maximum accumulation of events observed in G2/M phase at 5 and 10 μM concentration being 23% and 28% compared to the control (11%). Our studies clearly showed that increase in agent 3f concentration resulted in significant ($p < 0.01$) increase in G2/M.

3.2.6 Caspase activation. To confirm that compounds 3 cause apoptosis in HCT-116 and MCF-7 cells, the activation of caspases 3 and 7 was studied following exposure of cells (72 h) to 5 and 10 μM 3b' and 3f (Fig. 6). Significant dose-dependent caspase activation was observed after 72 h exposure of the cells to these agents (Fig. 5) which is consistent with apoptosis-induction. These data suggest that 3b' and 3f exert their cytotoxic activity *via* induction of caspase-dependent apoptosis.

3.2.7 Western blot assay. Confirmation of apoptosis-induction by 3f was further investigated by monitoring the expression levels of key apoptotic proteins. Poly (ADP-ribose) polymerase-1 (PARP-1) is a substrate of the caspase-3 protein,

Fig. 5 Cell-cycle histograms summarising the effect of **3f** on cell-cycle progression of HCT-116 (A) and MCF-7 (B) cells after 24 h of treatment at concentrations of 5 and 10 μM concentrations; 20 000 events were counted. Number of internal repeats three times. Primary flow cytometry traces are given in the ESI.†

Fig. 6 Caspase-3/7 activity of HCT-116 (A) and MCF-7 (B) cells after 72 h of treatment with **3b'** and **3f** at concentrations of 5 and 10 μM . Each experiment was repeated twice with five internal repeats. Bars and error bars refer to the mean \pm SD. * $p < 0.01$ vs. control, *** $p < 0.0005$ vs. control respectively.

present in HCT-116 cells and involved in a number of cellular processes. Its cleavage is indicative of apoptosis in HCT-116 cell lines.³⁰ Therefore, HCT-116 cells were treated with **3f** (5 and 10 μM , 24 h). The results obtained (Fig. 7) demonstrate that **3f** induces concentration-dependent PARP-1 cleavage, accompanied by down-regulation of whole PARP, suggesting apoptosis induction. The presence of cleaved PARP is also indicative of caspase activation, consistent with the caspase 3/7 results above.

Fig. 7 Effect of compound **3f** on expression of whole and cleaved PARP in HCT 116 cells. (A and B) Data are mean \pm SD of three independent experiments (ANOVA followed by Dunnett's test), significance is reported as * $p < 0.05$. (C) Representative western blots of HCT 116 lysates following treatment of cells with **3f** (5 and 10 μM) are given. The data are the mean SD of three independent experiments (ANOVA followed by Dunnett's test). Significance is reported as: * $p < 0.05$.

4. Conclusions

A library of 30 novel 2-(2-benzylidenehydrazinyl)-4-(4-cyanophenyl)thiazole derivatives (**3a-d'**) were synthesised. These demonstrate potent and selective antitumour activity against two cell lines representative of colorectal (HCT-116) and breast (MCF-7) cancer phenotypes. Compound **3f** ($R^3 = 2$ -hydroxy-3-methylphenyl) was found to be the most general efficient growth inhibitor with GI_{50} value $1.0 \pm 0.4 \mu\text{M}$ against MCF-7. Compound **3n** ($R^3 = 2,6\text{-Cl}_2\text{C}_6\text{H}_3$) exhibited highest inhibition potential (GI_{50} $1.1 \pm 0.5 \mu\text{M}$) against HCT-116. The selectivity of compounds towards the cancer cell lines over non-cancer cells was estimated by equivalent exposure to MRC-5 (normal fibroblasts). Only one compound **3w** ($R^3 = 2,4,6\text{-C}_6\text{H}_3\text{F}_3$) was more active against MRC-5, while all other compounds were more active against the carcinoma cell lines (often appreciable so e.g. $>5\times$ for **3b'**, $>10\times$ for **3f**). Cell cycle, caspase activation and western blot assays established that compounds **3b'** ($R^3 = 3$ -bromothiophene) and **3f** ($R^3 = 2$ -(OH)-3-MeC₆H₃) induce cancer cell death *via* caspase-dependent apoptosis and that these compounds are significantly more active than previously reported related thiazoles. It is too premature to speculate in depth on the exact mechanism of action of the compounds **3**. However, we note that very recently a related group of thiazoles were described that are potent kinase inhibitors.⁴⁰ It is possible that our own compounds operate similarly as preliminary experiments also showed ERK1/2 inhibition for **3f**. In conclusion, these synthetically accessible molecules are worthy of further preclinical evaluation including further examination against broad-spectrum cancer phenotypes and elucidation of their mechanism of action.

Author contributions

Tashfeen Akhtar planned the synthesis. Hasnain Mehmood synthesized the compounds and carried out all spectral analysis. Mustapha Musa carried out all the biological assays. Simon Woodward led the writing of the manuscript. Tracey Bradshaw and Andrew Nortcliffe contributed in biological results analysis and interpretation. Shahdat Hossan assisted in biological assays. Muhammad Haroon provided critical review and feedback.

Conflicts of interest

There are no conflicts to declare.
