Two acid-catalyzed tandem reactions between 4-hydroxy-1-methylquinolin-2(1*H*)-one and propargylic alcohols are described. Depending mainly on the propargylic alcohol used, these tandem reactions proceed *via* either a Friedel–Crafts-type allenylation followed by 6-*endo*-dig cyclization sequence to form pyrano[3,2-*c*]quinolones or a Friedel–Crafts-type alkylation and 5-*exo*-dig ring closure sequence to afford furo[3,2-*c*]quinolones in moderate-to-high yields. The pyrano[3,2-*c*]quinolones products could be further transformed to tetracyclic 4,9-dihydro-5*H*-cyclopenta[*lmn*]phenanthridin-5-one derivatives.

Introduction

Pyrano[3,2-*c*]quinolone is a structural motif occurring in a number of natural products[1] with a wide range of important biological activities such as anticancer,[2] antibacterial,[2] antimalarial,[3] antiinflammatory[4] and antifungal[5] properties and inhibition of calcium signaling,[6] TNF-α,[7] platelet aggregation,[8] and nitric oxide production.[9] For example, alkaloids zanthosimuline and huajiaosimuline[10] exhibit cytotoxicity against cancer cells, which is considered as potential anticancer agents (Scheme 1a). In addition, furo[3,2-*c*]quinolone derivatives such as araliopsine and almein are principally isolated from Rutaceae species[11] (Scheme 1a). Furo[3,2-*c*]quinolone hybrids are a significant class of angularly fused tricyclic compounds among the great variety of furan derivatives, which have been shown to exhibit biological and pharmacological activity such as antimicrobial, insecticidal, antiarrhythmic, antimalarial, antiplatelet aggregation and sedative,[1,12] photochemical treatment in clinic therapeutic field[13] and blocking activities of the voltage-gated potassium channel Kv1.3.[14] Consequently, a large number of procedures have been developed for the construction of these highly useful structures.[15] However, current methods more or less suffer from limited substrate scope, complicated catalyst or noble metal catalyst systems, not easily accessible starting materials, or multistep manipulations, the development of simple methods with wide product diversity is still highly desirable. Propargylic alcohols are readily accessible synthetic building blocks in organic synthesis.[16] Over the past few decades, the development of Lewis acid-catalyzed tandem annulations of propargylic alcohols has attracted interests from synthetic chemists, especially for the construction of various heterocyclic skeletons including pyrroles,[17] furans,[18] pyrans,[19]

carbazoles,[20] quinolines,[21] and tetrahydro-β-carbolines.[22] We herein describe the development of acid-catalyzed formal [3 + 3]/[3 + 2] cascade annulation processes for the construction of pyrano[3,2-*c*]quinolone/furo[3,2-*c*]quinolone derivatives from 4-hydroxy-1-methylquinoline-2(1*H*)-one and propargylic alcohols (Scheme 1b).

Results and discussion

Our initial studies commenced with the reaction of 4-hydroxy-1-methylquinolin-2(1*H*)-one **1** and propargylic alcohol **2a** (Table 1). No reaction occurred in the absence of an acid catalyst (Table 1, entry 1). Using 1,2-DCE (1,2-dichloroethane) as solvent, five Lewis acid catalysts and four Brønsted acid catalysts were screened and *p*TsOH·H_2O was found to be the most efficient one for this reaction (Table 1, entries 2–10). The product **3a** could be isolated in only 5% yield when the reaction was performed at 25 °C (Table 1, entry 11). Changing the solvent to THF, toluene, DMF (*N*,*N*-dimethylformamide) gave inferior results (Table 1, entries 12–14). Further screening of catalyst loading amount uncovered that 10 mol% was optimal for the reaction, while lower (5 mol%) or higher (20 mol%) loadings all led to no improvement in yields (Table 1, entries 15–16). Notably, relatively lower yields yet shorter reaction time were observed in the cases of metal Lewis acid catalysts, which might be due to faster decomposition of the propargylic alcohol **2a** under these conditions as observed by thin-layer chromatography (Table 1, entries 2–10). Moreover, it is worth mentioning that the reaction is tolerant of moisture and could be performed under air.

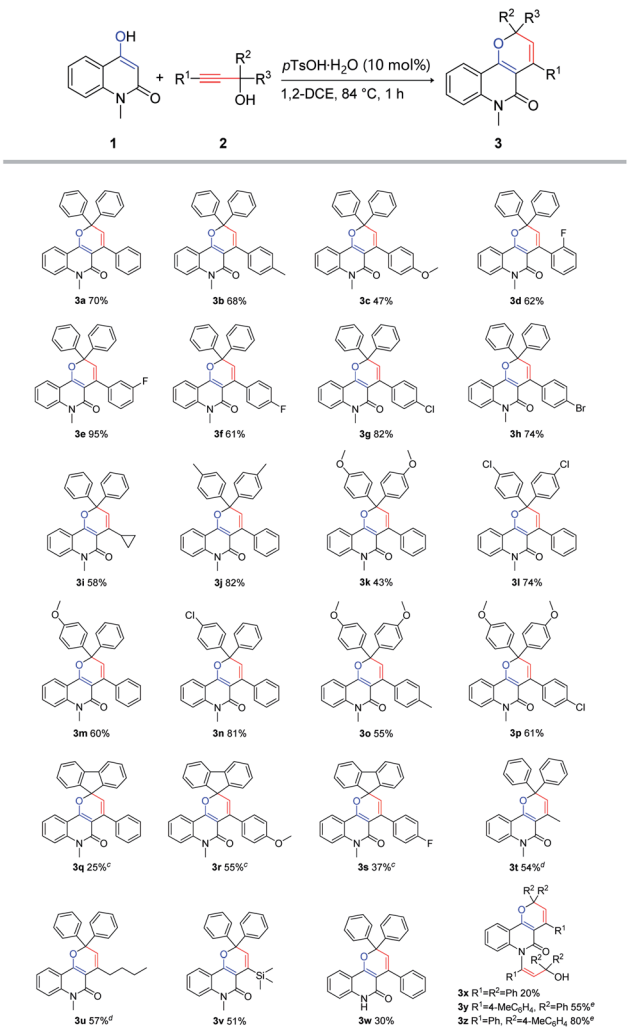
[a] Reaction conditions: **1** (0.5 mmol), **2a** (0.5 mmol), solvent (5 mL), under air, the reaction was monitored by TLC. [b] Yield of the isolated product. [c] Reaction was run at 25 °C. [d] Reaction was run at 66 °C. [e] Reaction was run at 90 °C.

With the optimized reaction conditions (Table 1, entry 7) in hand, a series of propargylic alcohols **2** were reacted with 4-hydroxy-1-methylquinolin-2(1*H*)-one **1** to examine the reaction scope with regard to the formation of pyrano[3,2-*c*]quinolone **3**. As depicted in Scheme 2, the transformation of various substituted propargylic alcohols **2** proceeded smoothly to deliver the corresponding pyrano[3,2-*c*]quinolone derivatives in moderate to good yields, irrespective of the electronic nature of the substituents. A variety of functional groups, including methyl, methoxyl, halogen and cyclopropyl substituents, were compatible with the reaction. Notably, cyclopropyl ring has a wide range of applications in drug molecular design[23] and propargylic alcohol bearing cyclopropyl was tolerated in the reaction conditions to generate the desired product **3i** in 58%



Scheme 2 Scope study with different propargylic alcohols **2**[a,b]. [a]Reaction conditions: **1** (0.5 mmol), **2** (0.5 mmol), *p*TsOH·H_2O (0.05 mmol), 1,2-DCE (5 mL), 84 °C. [b]Isolated yield refers to pyrano[3,2-*c*] quinolone derivatives. [c]Reaction time: 10 h. [d]Reaction time: 10 min. yield. In addition, other alkyl groups (R^1) such as methyl, *n*-butyl and trimethylsilyl also gave [3 + 3] products **3t–3u** in 51–57% yields. Moreover, when 9-fluorenyl-substituted propargylic alcohols **2q–2s** were subjected to the reaction conditions, spirocyclic products **3q–3s** could be formed in the yields of 24–55% albeit with much prolonged reaction time of 10 h. It was found that product **3x** was produced by hydroamination of N–H in **1** with alkyne in **2** beside normal product **3w**. Then products **3y** and **3z** were synthesized by adjusting molar ratio of the reaction. The structure of the products **3a** and **3z** was additionally confirmed by X-ray crystallographic analysis (see ESI† for details).

Based on the above experimental results, a plausible mechanism for the present cascade reactions is proposed (Scheme 3). First, in the presence of a Brønsted acid catalyst, propargylic alcohol **2a** is converted to the propargylic carbocation **I**, which is in equilibrium with the allenic form **II**.[24] The latter would undergo Friedel–Crafts-type reaction with **1** to form the allene intermediate **III**, which would be transformed to the final product **3a** *via* 6-*endo*-dig cyclization.[19f]

To further extend the scope of the current reaction, secondary propargylic alcohols **2u** was tested as substrate. Unexpectedly, 3-(1,3-diphenylprop-2-yn-1-yl)-4-hydroxy-1-methylquinolin-2(1*H*)-one **5a** was isolated instead of the desired pyrano[3,2-*c*]quinolone **3u** under the above optimized reaction conditions (Scheme 4). Given the recent reports on transition-metal-catalyzed direct heterocyclization of alkynes to construct furan frameworks,[25] $Cu(OTf)_2$ was then used to catalyze the reaction and to our delight, the ring-closure compound furo[3,2-*c*]quinolone **4a** was isolated as expected in 48% yield (Table 2, entry 2). Different Lewis acid catalysts were then screened (Table 2, entries 1–10), and CuOTf was found to be one of the best choice (Table 2, entry 3), while some catalysts could not transform **5a** to **4a** accordingly (Table 2, entries 1 and 4–7), indicating that the reactions were stuck at the stage of **5a**. The reaction hardly occurred at room temperature (Table 2, entry 8). The use of other solvents including THF, toluene, DMF or changing the catalyst loadings made no improvement in yield (Table 2, entries 11–16).

Next, the scope of the reaction with regard to the propargylic alcohols was investigated under the optimized reaction conditions, and the results were presented in Scheme 5. In general, the products **4** were produced in low to moderate yields (31–60%), regardless of the electronic nature and/or position of the substituents on the benzene rings (R^1 or R^2). It was worth noting that only stereodefined (*Z*)-furo[3,2-*c*]quinolones had been isolated. The structure of the product **4g** was additionally confirmed by X-ray crystallographic analysis (see ESI† for details). The primary alcohol such as 3-phenylprop-2-yn-1-ol was tested under the same reaction conditions for 24 hours, but no new product was detected and the staring material was recovered in 95% yield. Primary alcohol may not easily form primary carbocation under this reaction conditions.

To gain some insight into the reaction mechanism of this formal [3 + 2] annulation, some controlled experiments were conducted (Scheme 6a). Quenching the reaction between **1** and

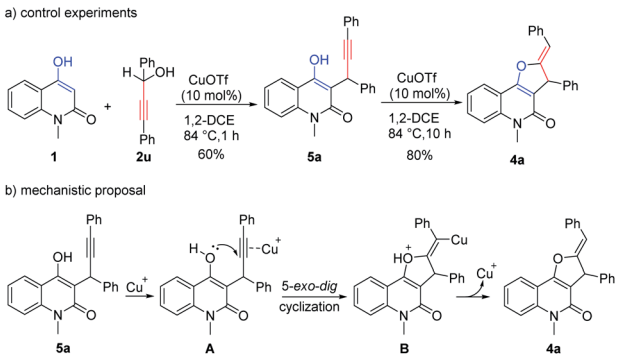
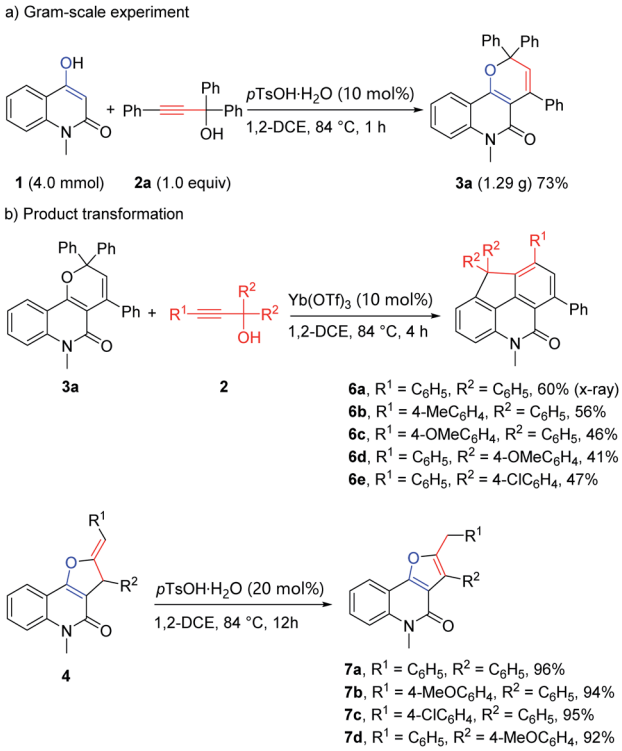


Scheme 6 Controlled experiments and mechanistic proposal for the [3 + 2]-annulation.

propargylic alcohols **2u** at an early stage (1 hour) gave the compound **5a** as the major product in 60% yield, indicating the Friedel–Crafts-type reaction was a relatively fast step in this process. Treatment of the isolated **5a** under the otherwise same reaction conditions produced the final product **4a** in 80% yield after 10 hours. On the basis of these results and literature reports,[25b,f] a mechanistic proposal for the conversion of **5a** to **4a** is depicted (Scheme 6b). The transformation began with the coordination of the triple bond to the copper(I) salt to facilitate the highly regioselective 5-*exo*-dig nucleophilic attack of the hydroxy group to form the intermediate **B**. Finally, protonolysis of **B** afforded **4a** and regenerated the catalyst.

To demonstrate the practicality of this formal [3 + 3] cascade annulation, a gram-scale experiment was carried out to provide desired product **3a** in 73% yield (Scheme 7a). Furthermore,



Scheme 7 Scale-up reaction and product transformations.

novel tetracyclic compounds **6a–6e** were forged from **3a** and propargylic alcohols **2** in 41–60% yields, which proceeded *via* sequential Diels–Alder reaction of 2*H*-pyran with alkynes followed by retro-Diels–Alder extrusion of benzophenone under thermal reaction conditions and Friedel–Crafts-type reaction at last.[26] Furo[3,2-*c*]quinolones **4** could be isomerized to **7** under the catalysis *p*TsOH·H_2O with excellent yields (Scheme 7b). The structure of the product **6a** was additionally confirmed by X-ray crystallographic analysis (see ESI† for details).

Conclusions

In conclusion, novel acid-catalyzed annulation reactions of propargylic alcohols with 4-hydroxy-1-methylquinolin-2(1*H*)-one were developed. This method provides a good atom- and step-economic way to useful pyrano[3,2-*c*]quinolone and furo[3,2-*c*]quinolone derivatives in moderate to good yields from readily accessible starting materials. Efforts towards the utilization of the propargylic alcohols to the synthesis of other useful cyclic compounds are underway in our laboratories.

Experimental section

General comments

Infrared spectra were obtained on a FTIR spectrometer. ^{1}H NMR spectra were recorded on 400 MHz spectrometer in $CDCl_3$ solution and the chemical shifts were reported relative to internal standard TMS (0 ppm). The following abbreviations are used to describe peak patterns where appropriate: br = broad, s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet.

Coupling constants are reported in Hertz (Hz). ^{13}C NMR were recorded on 100 MHz and referenced to the internal solvent signals (central peak is 77.00 ppm in $CDCl_3$). HRMS data were obtained using ESI ionization. Melting points were measured with micro melting point apparatus.

The propargylic alcohols **2** were prepared from phenylacetylene and benzophenone according to published methods.[27] Solvents were distilled prior to use. All chemicals were used as purchased unless otherwise mentioned.

General procedure for the synthesis of 3

A solution of 4-hydroxy-1-methylquinolin-2(1*H*)-one **1** (0.5 mmol), propargylic alcohols **2** (0.5 mmol) and *p*TsOH·H_2O (0.05 mmol) in 1,2-DCE (5 mL) was stirred under air at 84 °C for 1 h. After being cooled down to room temperature, the solvent was evaporated and the crude product was purified by silica gel column chromatography with petroleum ether/ethyl acetate (2 : 1, v/v).

General procedure for the synthesis of 4

A solution of 4-hydroxy-1-methylquinolin-2(1*H*)-one **1** (0.5 mmol), the secondary propargylic alcohols **2** (0.5 mmol) and CuOTf (0.05 mmol) in 1,2-DCE (5 mL) was stirred under air at 84 °C for 10 h. After being cooled down to room temperature, the solvent was evaporated and the crude product was purified by silica gel column chromatography with petroleum ether/ethyl acetate (2 : 1, v/v).

Synthesis of 5a

A solution of 4-hydroxy-1-methylquinolin-2(1*H*)-one **1** (0.5 mmol), propargylic alcohols **2u** (0.5 mmol) and CuOTf (0.05 mmol) in DCE (5 mL) was stirred under air at 84 °C for 1 h. After being cooled down to room temperature, the solvent was evaporated and the crude product was purified by silica gel column chromatography with petroleum ether/ethyl acetate (1 : 1, v/v).

General procedure for the synthesis of 6

A solution of pyrano[3,2-*c*]quinolone **3a** (0.5 mmol), propargylic alcohols **2** (0.6 mmol) and $Yb(OTf)_3$ (0.05 mmol) in 1,2-DCE (5 mL) was stirred under air at 84 °C for 4 h. After being cooled down to room temperature, the solvent was evaporated and the crude product was purified by silica gel column chromatography with petroleum ether/ethyl acetate (3 : 1, v/v).

General procedure for the synthesis of 7

A solution of furo[3,2-*c*]quinolones **4** (0.2 mmol) and *p*TsOH·H_2O (0.04 mmol) in 1,2-DCE (3 mL) was stirred under air at 84 °C for 12 h. After being cooled down to room temperature, the solvent was evaporated and the crude product was purified by silica gel column chromatography with petroleum ether/ethyl acetate (2 : 1, v/v).

Gram-scale synthesis for product 3a

A solution of 4-hydroxy-1-methylquinolin-2(1*H*)-one **1** (4.0 mmol), propargylic alcohols **2a** (4.0 mmol) and *p*TsOH·H_2O (0.4 mmol) in 1,2-DCE (20 mL) was stirred under air at 84 °C for 1 h. After being cooled down to room temperature, the solvent was evaporated and the crude product was purified by silica gel column chromatography with petroleum ether/ethyl acetate (2 : 1, v/v).

Author contributions

H. Y. conducted most of the synthetic experiments. X. G., Z. F., M.-F. W., D. F. and Z. C. conducted a part of the propargylic alcohols. S. W., Y. W. and M. W. directed the projects and wrote the manuscript. All of the authors approved the final version of the manuscript.
