# Gold nanoparticle decorated dithiocarbamate modified natural boehmite as a catalyst for the synthesis of biologically essential propargylamines†

Elham Zarenezhad,<sup>a</sup> Reza Taghavi,<sup>b</sup> Parisa Kamrani,<sup>b</sup> Mojtaba Farjam<sup>a</sup> and Sadegh Rostamnia<sup>\*b</sup>

Here, we prepare an Au NP decorated dithiocarbamate functionalized boehmite ( $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·Au<sub>NPs</sub>). This stepwise synthetic method gives an efficient, cost-effective, and green heterogenous Au-based nanocatalyst for the A<sup>3</sup>-coupling preparation of the biologically essential propargylamines. Different characterization methods, including FT-IR, XRD, SEM, TEM, EDX spectra, and elemental SEM-mapping, were employed to investigate the structure of the manufactured  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·Au<sub>NPs</sub>. Then we used the prepared composite as a heterogeneous gold-based nanocatalyst for the one-pot A<sup>3</sup>-coupling preparation of propargyl amines by reacting a variety of aldehydes, amines, and phenylacetylene which exhibited promising results.

## 1 Introduction

The term A<sup>3</sup>-coupling reaction refers to the one-pot three-component reaction of an aldehyde, an amine, and a terminal alkyne in the presence of a transition metal to yield propargyl amines. Due to the broad application of such compounds in organic synthesis, especially as intermediates for preparing medicinally essential compounds, the A<sup>3</sup>-coupling preparation of propargyl amines has attracted a great deal of attention in the past two decades, and considerable progress has been achieved.<sup>1,2</sup> This class of compounds is widely applied toward neurodegenerative disorders such as Alzheimer's and Parkinson's diseases. Many approved drugs, including rasagiline (I), pargyline (II), and selegiline (III) have a propargylamine framework. Such compounds possess monoamine oxidase (MAO) inhibitory properties, and the use of these compounds has been reported in mitochondrial protection and providing neuronal properties (Scheme 1).<sup>3–5</sup> Utilization of metal NPs helps the progress of this reaction by increasing the acidity of the C–H bond of the terminal alkyne.<sup>6</sup> To date, various transition metal NPs such as Au, Cu, and Ag have been employed to promote this reaction.<sup>7–9</sup>

Recently, gold NPs were applied as catalysts to promote various reactions, including degradation of environmental pollution, hydrogen generation, organic transformation, *etc.*<sup>10–13</sup> Such efforts help to disbelieve the traditional idea that gold suffers from the lack of catalytic properties. There are various reports on preparing propargyl amines using Au NPs as catalysts.<sup>14–17</sup> Gold NPs increases the selectivity and yield of the preparation of propargyl amines due to their small size, high surface-to-volume ratio, and intrinsic properties.<sup>6</sup> The catalytic properties of the gold NPs are directly influenced by their size and shape. When the gold NPs grow to the micro size regime, their catalytic properties are entirely quenching.<sup>18</sup> Therefore, various supports were employed to prevent the aggregation of gold NPs.

The critical factor for preparing stable metallic NPs and discovering their catalytic properties was using supports and stabilizers.<sup>19–21</sup> To date, different supports, such as metal-organic frameworks, nanocrystalline magnesium oxide, alumina, cerium oxide, magnetic NPs, *etc.*, are employed for stabilization and modification of the catalytic performance of Au NPs for the A<sup>3</sup>-coupling reaction.<sup>7,22–25</sup> A metal NP supported on a nano-size heterogenous support benefits from the high selectivity, preventing the aggregation of the metal NPs, high dispersion in a liquid medium, and high reusability.<sup>18</sup>

Boehmite ( $\gamma$ -AlO(OH)), as a binary layer derivative of aluminum, finds its way into heterogeneous catalyst fields due to its insolubility, inexpensive precursors, commercial availability, non-toxicity, corrosion resistance, high chemical and mechanical stability, high dispersity, and accessible surface modification.<sup>26,27</sup> The layers of boehmite are connected through

Scheme 1 Example of approved drugs having a propargylamines framework.

hydrogen bonding, and a high-density layer of hydroxyl groups covers its surface. Such structure allows easy modification of its surface for desired applications.<sup>26</sup>

In this report, we modified the surface of the commercially available natural boehmite with the APTES ligand. Then,  $\text{-NH}_2$  modified boehmite was further mutated to the dithiocarbamate functional group decorated composite by adding  $\text{CS}_2$  and was utilized to support the stabilization of Au NPs. The resulting  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$  catalyst was used as a heterogeneous catalyst for  $\text{A}^3$ -coupling preparation of propargyl amines, which exhibited excellent results.

## 2 Experimental

### 2.1 Synthesis of $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}$ nanoparticles

In a 100 mL round-bottom flask, to 40 mL anhydrous toluene solution of boehmite (2 g), 4 mL of (3-aminopropyl) triethoxysilane (APTES) was added dropwise. The obtained solution was heated to 100 °C and stirred for 48 h.  $\gamma\text{-AlO(OH)@C-NH}_2$  was washed with  $\text{H}_2\text{O}$  and dried in an oven overnight. Next,  $\gamma\text{-AlO(OH)@C-NH}_2$  was dispersed in 20 mL ethanol under sonication for 10 min. 2.2 mL  $\text{CS}_2$  was added to the above solution and stirred for another 12 h. Dithiocarbamate functionalized boehmite ( $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}$ ) was washed with ethanol several times and dried at 70 °C overnight.

### 2.2 Immobilization of $\text{Au}_{\text{NPs}}$ onto the surface of $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}$

Immobilization of Au nanoparticles onto the surface of dithiocarbamate functionalized Boehmite ( $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}$ ) was performed based on the reported method in the literature.<sup>28</sup> Generally, 0.3 g of  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}$  was added to 10 mL of 0.12 M aqueous solution of  $\text{HAuCl}_4$  gradually under sonication. This solution kept stirring for 24 h. The heterogeneous catalyst was separated from the solution by filtration and washed with ethanol (EtOH) for several times to gain  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{AuCl}_3$ . Finally, 5 mL of freshly prepared  $\text{NaBH}_4$  in methanol ( $0.2\text{ mol L}^{-1}$ ) was added dropwise to the mixture of as prepared  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{AuCl}_3$ . This solution was stirred for another 30 min, then filtered and washed with methanol to obtain pure  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$ .

### 2.3 General synthesis of propargyl amines

In a general process, one mmol of aromatic aldehyde, 1.2 mmol of amine, 1.3 mmol of phenylacetylene, and 0.4 g of

$\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$  as a heterogeneous catalyst, and one mmol of  $\text{Cs}_2\text{CO}_3$  as a base were added to 4 mL of  $\text{CHCl}_3$  at 60 °C and stirred for an appropriate time (Table 2). Next, the heterogeneous catalyst was removed from the solution mixture simply by filtration. Finally, the reaction solvent was evaporated, and corresponding propargyl amines were purified by plate-chromatography. The resulting propargyl amines were investigated by  $^1\text{H}$  NMR and  $^{13}\text{C}$  NMR (ESI<sup>†</sup>).

## 3 Results and discussion

Due to our interest in developing green and sustainable methodologies for various organic synthesis reactions, herein we report a facile and efficient synthesis of propargyl amines *via*  $\text{A}^3$ -coupling reaction using aldehyde, amine, and alkyne in the presence of the  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$  nanocatalyst. First, natural boehmite ( $\gamma\text{-AlO(OH)}$ ) was functionalized with the APTES to give an amine-rich surface. Then,  $\text{CS}_2$  was added to the amine-functionalized boehmite solution to cover its surface with a skin of dithiocarbamate (DTC). Finally, Au NPs were stabilized on the surface of the dithiocarbamate-functionalized boehmite to prepare the  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$  catalyst. We employed the crafted nanocomposite as a catalyst for the  $\text{A}^3$ -coupling reaction of aldehydes and amines with phenylacetylene under optimal conditions. A schematic illustration of the  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$  synthesis is shown in Scheme 2.

Fig. 1 represents the FT-IR spectra of as-synthesized bare  $\gamma\text{-AlO(OH)}$ ,  $\gamma\text{-AlO(OH)@C-NH}_2$ ,  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}$ , and  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$ . For the bare  $\gamma\text{-AlO(OH)}$ , the peak at 469 regarding octahedral morphology of Al. Bending vibration of Al-OH appeared at  $1099\text{ cm}^{-1}$ , and the stretching vibration of the OH group linked to the Al showed itself at  $3446\text{ cm}^{-1}$ . For the  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}$ , peaks in  $2900\text{--}3000\text{ cm}^{-1}$  and  $3426\text{ cm}^{-1}$  regions, probably regarding C-H of carbon groups of the APTES, while O-H functional groups probably attribute to the surface of boehmite. As shown in the spectra of  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$ , the characteristic peak of -NH at  $1646\text{ cm}^{-1}$  is red shifted to  $1632\text{ cm}^{-1}$  due to the surface change of bifunctional hybrid nanomaterials. In this case, the characteristic of C=S groups revealed itself at  $1562\text{ cm}^{-1}$ , and the broadband of the boehmite covers its other characteristics. These can be proof of the successful synthesis of  $\gamma\text{-AlO(OH)@C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$ . To further prove the formation of the catalyst,

Fig. 3 represents the XRD pattern of the bare  $\gamma$ -AlO(OH) and  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·Au<sub>NPS</sub>. The XRD pattern of the bare boehmite shows all the characteristics peaks with a good

**Fig. 1** FTIR spectrum of  $\gamma$ -AlO(OH),  $\gamma$ -AlO(OH)C-NH<sub>2</sub>,  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H,  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs.

FESEM and TEM were employed to investigate the morphology of the synthesized catalyst (Fig. 4). The FESEM image (Fig. 4a) reveals agglomerated morphology of  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H-Au<sub>NPs</sub> catalyst. The TEM images provide a more detailed insight into the surface of the ensembled catalyst and prove that the functionalization of its surface with dithiocarbamate perfectly prevents aggregation of Au NPs (Fig. 4c and d).

We lunch the study of catalytic performance of the  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·Au<sub>NPs</sub> toward the A<sup>3</sup>-coupling reaction by using the morpholine, benzaldehyde, and phenylacetylene as the precursors. In this context, we examine the effects of various parameters such as temperature, reaction solvents, reaction time, base, and amount of catalyst to reach the optimum condition. We initiated our study by probing the effect of various solvents on the progress of this reaction (Table 1). Results show that the EtOH and EG solvent restricted the progress of the reaction while other solvents such as acetonitrile and chloroform promoted the A<sup>3</sup>-coupling reaction in good yield. Table 1 indicates that 0.1 mol% of gold NPs onto the  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·Au<sub>NPs</sub> in CHCl<sub>3</sub> solvent gives the most satisfying results (Table 1, entry 5).

**Fig. 3** XRD pattern of  $\gamma\text{-AlO(OH)}@\text{C-NHCS}_2\text{H}\cdot\text{Au}_{\text{NPs}}$  and  $\gamma\text{-AlO(OH)}$ .

Fig. 4 (a) SEM  $\gamma$ -AlO(OH), (b) SEM  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs. (c and d) TEM of  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs.

investigated by TLC. The maximum yield was achieved after 12 h, as is evident.

Optimization of the catalyst amount was performed by testing the catalytic performance of several amounts of  $\gamma$ -

AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs in the progress of the model reaction. The results indicate that using 0.1 mol% of  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs (per each mol of the substrate) leads to the maximum yield (Fig. 6).

After optimizing the condition of the model reaction (0.1 mol% of gold NPs onto the  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs, Cs<sub>2</sub>CO<sub>3</sub> as the base and 60 °C as reaction temperature), the generality of the catalyst toward the A<sup>3</sup>-coupling reaction has been tested in the presence of a variety of aldehydes, amines, and phenylacetylene. All the subsequent reactions have been

performed at the optimum condition in the presence of Cs<sub>2</sub>CO<sub>3</sub> as the base. The results of this study are summarized in Table 2. These results indicate that the proposed catalyst can promote the A<sup>3</sup>-coupling reaction for various aldehydes with the electron-

donor or electron-withdrawing groups in the ortho or meta position of the aromatic ring. Table 2 also specifies that the reaction's progress is influenced by the electronic

Fig. 7 (a) Recyclability of  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs for model A<sup>3</sup>-coupling reaction (b) TEM image of the proposed catalyst after the 4<sup>th</sup> recycling period.

Scheme 3 A plausible mechanism for the Au-catalyzed A<sup>3</sup>-coupling.

characteristics of the aromatic ring of the aldehyde and the yield of the reaction differs from case to case.

Reusability of the catalyst is a crucial feature for its scalable applications. To test the reusability of the proposed  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs catalyst for A<sup>3</sup>-coupling reaction of the model reaction, the catalyst was separated from the reaction medium and used for the same reaction at optimum condition for five times. After each run, the catalyst was thoroughly washed with the ethyl acetate several times to ensure the purity of the recycled catalyst, so the reaction kinetic be the same for all the cycles. As shown in Fig. 7a, the yield of the reaction remains almost the same for four cycles but it suddenly drops in the fifth cycle.

Atomic absorption spectrometry (AAS) was employed to track the presence of the Au NPs in the reaction solution, which proves the existence of negligible amounts of the Au NPs in the solution medium, even after four cycles. TEM image of the catalyst after the 4<sup>th</sup> run reveals its formidable firmness under the reaction conditions (Fig. 7b).

It is appraised that the  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs catalyst helps the progress of the reaction *via* the Heaney and co-workers mechanism<sup>66</sup>. At first, gold NPs decorated catalyst helps the activation of C–H of phenylacetylene. Then, coordination of the obtained complex with iminium ion gives an intermediate. Finally, the addition of the alkynylide to iminium ion results in desired propargyl amines (Scheme 3).

## 4 Conclusion

In conclusion, we synthesis an Au NPs decorated dithiocarbamate functionalized boehmite as a cost-effective, green, and efficient heterogeneous catalyst for the one-pot three-component A<sup>3</sup>-coupling preparation of propargyl amines at 60 °C. The  $\gamma$ -AlO(OH)@C-NHCS<sub>2</sub>H·AuNPs catalyst managed to preserve its structure during the preparation procedure and

successfully stabilizes monodispersed Au NPs perfectly. The proposed catalyst promotes the preparation of propargyl amines in good yields with a variety of aromatic aldehydes, possessing electron donor and electron-withdrawing groups in different positions of the aromatic ring and showing good recyclability up to four cycles.
