# 2D TiVCT<sub>x</sub> layered nanosheets grown on nickel foam as highly efficient electrocatalysts for the hydrogen evolution reaction

Yi Wen,  Junsheng Yang,\* Haoran Zou, Yiquan Fan, Jie Li, Yijian Kuang, Wenkang Liu, Kaisong Zhang and Lieqiang Xiong

Exploring highly efficient and durable catalysts for the hydrogen evolution reaction (HER) is crucial for the hydrogen economy and environmental protection issues. Numerous studies have now found that transition metal carbide MXenes are ideal candidates as catalysts for the hydrogen evolution reaction. However, MXenes are inclined to easily undergo lamellar structure agglomeration and stacking, which impedes their further applications. Besides, most of the extant research has focused on single transition metal carbides, and the investigation of double transition metal carbide MXenes is rather rare. In this research work, a three-dimensional (3D) TiVCT<sub>x</sub>-based conductive electrode was constructed by depositing 2D TiVCT<sub>x</sub> nanosheets on 3D network structured nickel foam (NF) to synthesize a hybrid electrode material (abbreviated as TiVCT<sub>x</sub>@NF). TiVCT<sub>x</sub>@NF exhibits efficient electrochemical properties with a low overpotential of 151 mV at 10 mA cm<sup>-2</sup> and a small Tafel slope of 116 mV dec<sup>-1</sup>. Benefitting from the open layer structure and strong interfacial coupling effect, compared to the pristine structure, the resulting TiVCT<sub>x</sub>@NF has greatly increased active sites for the hydrogen evolution reaction (HER) and encounters less resistance for charge transfer. In addition, TiVCT<sub>x</sub>@NF exhibits better stability in long-term acidic electrolytes. This work provides a tactic to prepare three-dimensional network electrode materials and broadens the application of single transition metal carbide MXenes as water splitting electrodes in the HER, which is beneficial to the application of noble metal-free electrocatalysts.

## 1. Introduction

In recent years, due to the combustion and emission of a variety of chemical fuels, energy shortage and environmental pollution have become global problems. The development of various new and renewable energy sources is an important issue at present. As a secondary energy source, hydrogen energy is clean, efficient, and can be easily stored and transported, and is thus regarded as an ideal energy carrier.<sup>1,2</sup> Water splitting is one of the most promising technologies for industrial hydrogen production.<sup>3</sup> The best electrocatalysts for the HER are platinum electrodes or noble metals; however, due to the rising price of precious metals, the improvement of the catalytic activity and cost-effectiveness of existing metal hydrogen evolution electrodes has become a primary issue for manufacturers.<sup>4,5</sup>

MXenes are two-dimensional transition metal compounds, which can be expressed as M<sub>n+1</sub>X<sub>n</sub>T<sub>x</sub> (where M represents a transition metal element, X stands for C or N, and T represents -OH, -F and other functional groups). Many studies<sup>6-9</sup>

have shown that MXenes are excellent materials for water electrolysis due to their high specific surface area, good electrical conductivity and stability, which has aroused the extensive interest of scholars. Tang *et al.*<sup>10</sup> proposed that due to the features of the MXene Ti<sub>3</sub>C<sub>2</sub> such as its large surface area, excellent conductivity and adjustable terminations, it can be applied in the hydrogen evolution reaction (HER). Huang *et al.*<sup>11</sup> prepared MoS<sub>2</sub>/Ti<sub>3</sub>C<sub>2</sub> composite heterostructures by the hydrothermal method. When used as a HER electrocatalyst, MoS<sub>2</sub>/Ti<sub>3</sub>C<sub>2</sub> exhibits excellent electrochemical activity with a low overpotential of ~280 mV at 10 mA cm<sup>-2</sup>. Compared to MoS<sub>2</sub> nanosheets, the catalytic current density induced by MoS<sub>2</sub>/Ti<sub>3</sub>C<sub>2</sub> at an overpotential of ~400 mV is more than 6.2 times that of the MoS<sub>2</sub> nanosheets. Le *et al.*<sup>12</sup> used ammonia heat treatment to enhance the hydrogen evolution catalysis of Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXenes by modification with a nitrogen heteroatom. As shown in the experimental results, compared to the Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene, the nitrogen-doped Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> annealed at 600 °C exhibited superior HER electrocatalytic performance with an overpotential as low as 198 mV at 10 mA cm<sup>-2</sup> and a much smaller Tafel slope of 92 mV dec<sup>-1</sup>. Liu *et al.*<sup>13</sup> mixed H<sub>8</sub>MoN<sub>2</sub>S<sub>4</sub> and Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> to prepare MoS<sub>2</sub>/Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> layered nanomaterials. The active sites of the two-

School of Mechanical Engineering, Wuhan Polytechnic University, Wuhan, 430023, Hubei, China. E-mail: yangjunsheng2008@163.com; Fax: +86-027-85617871

dimensional nanomaterials are greatly increased, the exchange current density is more than 25 times that of MoS<sub>2</sub>, and the electrochemical performance is significantly improved.

With the deepening of research, scholars have tried to introduce transition metal elements into MXenes to obtain different electrochemical properties. According to a previous study,<sup>14</sup> compared to Ti<sub>3</sub>C<sub>2</sub>, the TiVCT<sub>x</sub> MXene has some unique electrochemical properties due to the addition of the transition metal element V. Yazdanparast *et al.*<sup>15</sup> successfully obtained MXene thin films of TiVCT<sub>x</sub> by etching and layering. The obtained TiVCT<sub>x</sub> nanosheets possess a large specific surface area and multiple active sites, and the functional group structure on the TiVCT<sub>x</sub> MXene has excellent stability. Li *et al.*<sup>16</sup> investigated the electrochemical properties of the TiVCT<sub>x</sub> MXene, and the results showed that the TiVCT<sub>x</sub> MXene exhibited metallic properties with high electronic conductivity, and its comprehensive electrochemical performance is better than that of the Ti<sub>2</sub>C MXene. Li *et al.*<sup>17</sup> prepared TiVCT<sub>x</sub> MXenes and investigated their electrochemical properties, and discovered that the performance of the TiVCT<sub>x</sub> MXenes did not yield the desired results. They then used *o*-phenylenediamine (*o*-PD) as a metamer for oxidant-free polymerization and mixed it with the prepared TiVCT<sub>x</sub> to obtain three-dimensionally stable TiVCT<sub>x</sub>/poly-*o*-PD hybrids. Electrochemical studies have shown that the TiVCT<sub>x</sub>/poly-*o*-PD hybrid possessed a high specific surface area, excellent cycling stability, and improved comprehensive electrochemical performance. Nevertheless, there are few reports on the hydrogen evolution performance of the TiVCT<sub>x</sub> MXene in the electrolysis of water.

Ni is an abundant transition metal element with the features of low cost and high catalytic activity in hydrogen production by water electrolysis.<sup>18</sup> Previous studies have shown that the hybridization of nickel foam (NF) is beneficial to the improvement of the electrochemical performance of nanomaterials.<sup>19–22</sup> Herein, a new strategy is proposed, and the novel hybrid TiVCT<sub>x</sub>@nickel foam (NF) is obtained by compounding nickel foam with layered MXene nanosheets. The surface element distribution, morphology and structure of TiVCT<sub>x</sub>@NF are systematically studied, and the electrochemical hydrogen evolution performance and stability of the hybrid nanomaterials are further investigated.

## 2. Experimental

### 2.1 Preparation of TiVAIC powders

In a preliminary work, we have successfully prepared TiVAIC powders using TiH<sub>2</sub> (99.6% pure), V (99.6% pure), Al (99.5% pure) and C (99.8% pure) powders with an atomic ratio of 1 : 1 : 1.3 : 1 by the activation reaction sintering method at a sintering temperature of 1500 °C, and the specific details about the preparation of the MAX TiVAIC are shown in Zou's study.<sup>23</sup> Then, the fabricated TiVAIC powders were broken by a crushing machine (GJ500-1, Hangzhou, China) and sieved through a mesh 325 sieve.

### 2.2 Preparation of TiVCT<sub>x</sub> nanosheets

Layered TiVCT<sub>x</sub> was synthesized by liquid etching of the as-prepared TiVAIC powders. The etching was carried out by immersing the TiVAIC powders in a 40% HF solution with a solid-to-liquid ratio of 1 : 20 and stirred at 500 rpm for 48 h at 45 °C. Then, the suspension was centrifuged 7–8 times (3 min at a time) at 3500 rpm to separate the multilayered MXene. The centrifuged suspension supernatant was washed and filtered with distilled water until the pH of the supernatant was equal to ~7. After that, the multilayered TiVCT<sub>x</sub> MXene was obtained. The obtained multilayered TiVCT<sub>x</sub> was stirred with 25% TMAOH solution for 24 h at room temperature. Then, the mixture was centrifuged at 8500 rpm for 5 min, and the supernatant was collected. The TiVCT<sub>x</sub> nanosheets were obtained by washing the supernatant with distilled water until the pH of the supernatant was neutral and filtered. The final TiVCT<sub>x</sub> nanosheet powders were dried at 50 °C for 12 h in a vacuum oven (DZF-6020, Shanghai, China).

### 2.3 Preparation of TiVCT<sub>x</sub> nanosheets@NF

After sonication for 1 h, 5 mg of the TiVCT<sub>x</sub> nanosheets and 20 μL Nafion solution (5 wt%) were dispersed in a 980 μL deionized water/ethanol mixed solution with a volume ratio of 1 : 1. Then, 5 μL of the mixed solution was evenly added to commercial NF (1 cm × 1 cm). After that, the NF loaded with the catalyst was put into a vacuum sintering furnace and sintered in vacuum at 300 °C for 2 h, and TiVCT<sub>x</sub> nanosheets@NF was obtained.

### 2.4 Characterization

The sample powders were analyzed by X-ray diffraction (XRD, D/MAX-rA) using an X-ray diffractometer equipped with Cu Kα radiation (λ = 1.541 Å). The morphologies of the samples were characterized by scanning electron microscopy (SEM, JSM-5600LV) and transmission electron microscopy (TEM, F200X). The elemental composition of the samples was characterized by scanning electron microscopy equipped with energy dispersive X-ray spectrometry (EDS). The sample surface was characterized by X-ray photoelectron spectroscopy using Mg Kα as the excitation source.

### 2.5 Electrocatalytic performance evaluation

All electrochemical measurements were carried out using a typical three-electrode configuration with an electrochemical workstation (CHI660E, Shanghai, China). TiVCT<sub>x</sub> nanosheets@NF was used as the working electrode (the loading weight is 0.025 mg cm<sup>-2</sup>), and an Ag/AgCl electrode and glassy carbon electrode were used as the reference electrode and counter electrode, respectively. The HER testing was performed in 0.5 mol L<sup>-1</sup> H<sub>2</sub>SO<sub>4</sub>.

For the HER, the potential calibration of the reversible hydrogen electrode (RHE) was calibrated with respect to the following equation:<sup>24</sup>

$$E(\text{RHE}) = E(\text{Ag/AgCl}) + 0.0591 \text{ pH} + 0.196 \quad (1)$$

Cyclic voltammetry (CV) was used to measure the double-layer capacitance ( $C_{dl}$ ), which was recorded from  $-6$  to  $94$  mV *vs.* RHE at scan rates from  $20$  to  $120$  mV  $s^{-1}$  at an interval of  $20$  mV  $s^{-1}$ . Linear sweep voltammetry (LSV) was performed at a scan rate of  $10$  mV  $s^{-1}$  with 90% IR compensation by sweeping the potential from  $0$  to  $-0.6$  V *vs.* RHE. Electrochemical impedance spectroscopy (EIS) was performed in a frequency range of  $100$  kHz to  $0.01$  Hz at an overpotential of open-circuit potential (OCP). The long-term stability test was performed by successive CV at a scan rate of  $100$  mV  $s^{-1}$  for 1000 cycles. Lastly, chronoamperometric measurements at the requisite overpotential to afford  $10$  mA  $cm^{-2}$  were used to evaluate the long-term durability.

### 3. Results and discussion

In this study, multi-layered  $TiVCT_x$  MXenes with different abundant functional groups were successfully prepared through the etching method of removing Al atoms from  $TiAlC$  powder using HF. Ultrathin nanostructured  $TiVCT_x$  was obtained by exfoliation. Next, the  $TiVCT_x$  nanosheet powders were loaded on commercial nickel foam (NF), and then placed in a vacuum furnace for annealing at  $300$  °C for  $2$  h to obtain  $TiVCT_x@NF$  hybrids (Fig. 1). Fig. 2(a) shows an SEM image of the etched products. It can be clearly seen that a lamellar morphology appears, and these nanosheets are produced by HF etching away the Al in  $TiAlC$ . In order to acquire the micro-morphological and structural information of the  $TiVCT_x$  MXene in more detail, Fig. 2(b) shows a TEM image of multilayer

$TiVCT_x$  and Fig. 2(c) shows a TEM image of few-layer  $TiVCT_x$ . The multilayered  $TiVCT_x$  nanosheets exhibit clearly visible ripples, indicating the ultrathin feature of the  $TiVCT_x$  nanosheets. The multilayered  $TiVCT_x$  nanosheets present an unordered vertical arrangement. By calculation, the average nanolayer spacing is  $2.2$  nm (Fig. 2(d and e)).

Fig. 3(a) shows the XRD patterns of  $TiAlC$  and the  $TiVCT_x$  MXene after the HF solution etching. It can be seen that the XRD patterns before and after  $TiAlC$  etching are obviously different, indicating the successful synthesis of the  $TiVCT_x$  MXene. After the etching of  $TiAlC$ , the diffraction peak intensity at  $40.38^\circ$  is significantly weakened.

Additionally, in the spectrum of the  $TiVCT_x$  MXene, a diffraction peak appears at a small angle of  $6.85^\circ$ , indicating the introduction of other molecules (according to a study by Li *et al.*<sup>17</sup>). Fig. 3(b) shows the surface element distribution of the  $TiVCT_x$  MXene. It can be seen that the Ti, V, C, F, and O elements are well and uniformly dispersed on the nanosheet structure. The presence of the element O is due to the intercalation of oxygen-containing groups between the nanosheets.

Fig. 4 shows the micromorphology and the results of the elemental distribution of the  $TiVCT_x@NF$  hybrid materials. Fig. 4(a) exhibits the microstructure of the porous nickel foam framework. In Fig. 4(b), it can be clearly seen that plenty of white nanoparticles are attached to the surface of the nickel foam after hydrothermal treatment. In Fig. 4(c), it can be obviously seen that  $TiVCT_x@NF$  is composed of Ni, Ti, O, C, F and V, and the six elements are uniformly distributed, indicating the successful synthesis of  $TiVCT_x@NF$ .

Fig. 2 (a) SEM images of layered TiVCT<sub>x</sub>. (b and c) TEM images of TiVCT<sub>x</sub>. (d–f) The interlayer analysis of TiVCT<sub>x</sub>.

As shown in Fig. 5, XPS was used to analyze the element valence composition of TiVCT<sub>x</sub>, and PeakFit was used to perform peak processing on the XPS data, and the corresponding characteristic peaks were fixed according to the binding energy. As shown in Fig. 5(b), the spectrum of Ti 2p contains two singlets and one doublet; the peaks at 454.8 eV and 455.36 eV correspond to Ti–C; the peaks at 456.3 eV, 459.2 eV and 464.70 eV correspond to Ti–O; and the peak at 461 eV corresponds to Ti–F. As shown in Fig. 5(c), the binding energy peaks identified for TiVCT<sub>x</sub> at 281.6, 282.1, 285.0, 285.3, and 286.3 eV correspond to C=O, C–O, graphitic C–C, C–V, and C–Ti. As shown in Fig. 5(d), the spectrum of F 1s contains two

singlets and one doublet. The spectrum is easily fitted by one doublet peak of F–C, which contains two peaks at binding energies of 687.5 eV and 688.5 eV. The peak at 685.4 eV is related to the characteristic F–V, and the peak at 686.4 eV corresponds to C–Ti–F<sub>x</sub>. The results suggest the embedding of –F in the MXene layered structure. As shown in Fig. 5(e), the spectra of V 2p and O 1s contain V–C, V<sub>x</sub>O<sub>y</sub>, V–F, O–Ti, O=V and –OH peaks, indicating the successful etching of Al and the combination of O. In general, it can be clearly seen from the above results that the Al atomic layer is completely etched, and new functional groups (–F, –OH, –O) are introduced. The addition of these functional groups (–F, –OH, –O) may increase the HER catalytic

Fig. 3 (a) XRD patterns of the TiVCT<sub>x</sub> MXene and TiVAIC powder. (b) Elemental mapping images of layered TiVCT<sub>x</sub> nanosheets.

activity of the MXene nanosheets.<sup>25</sup> With the increased adsorption energy of protons, the charge transfer resistance decreases. Due to the surface functional groups, the TiVCT<sub>x</sub> nanosheets are negatively charged. Combining the analysis results, the following equations are obtained:

Electrochemical double-layer capacitance ( $C_{dl}$ ) is an electrochemical parameter that can evaluate the difference in the electrochemically active surface area of different samples and

can be determined by cyclic voltammetry (CV).<sup>26</sup> The number of active sites is one of the important factors determining the HER activity, and the electrochemically active surface area depends on the number of active sites. Fig. 6(a), (c) and (e) present the cyclic voltammetry curves of TiVCT<sub>x</sub>@NF, TiVCT<sub>x</sub> and commercial Pt/C, respectively, measured at scan rates of 20–120 mV s<sup>−1</sup> with an interval of 20 mV s<sup>−1</sup>. Fig. 6(b), (d) and (f) present the curves of capacitive current *versus* scan rate for TiVCT<sub>x</sub>@NF, TiVCT<sub>x</sub> and commercial Pt/C at 0.15 V, respectively. It can be seen from the above results that the  $C_{dl}$  of TiVCT<sub>x</sub>@NF is 26.9 mF cm<sup>−2</sup>, which is much larger than that of TiVCT<sub>x</sub> (3.8 mF cm<sup>−2</sup>), indicating that through the combination with nickel foam, the specific surface area is increased, the active sites are increased, and the hydrogen evolution catalytic performance is enhanced. Besides, the  $C_{dl}$  of TiVCT<sub>x</sub>@NF is close to the  $C_{dl}$  of the Pt/C electrode (31.8 mF cm<sup>−2</sup>).

In order to explain the good electrochemical behavior of the TiVCT<sub>x</sub> nanosheets, the relevant tests on their hydrogen evolution performance were carried out. Using a standard three-electrode electrochemical system, the electrochemical activity of TiVCT<sub>x</sub> and its hybrid products for the HER was tested in a 0.5 mol L<sup>−1</sup> H<sub>2</sub>SO<sub>4</sub> electrolyte. Besides, the commercial platinum–carbon catalyst (10 wt% Pt/C) with extremely high hydrogen evolution activity and pure nickel foam (NF) were used as references in this test. Fig. 7(a) shows the HER polarization curves of TiVCT<sub>x</sub>, NF, TiVCT<sub>x</sub>@NF and commercial platinum–carbon in 0.5 mol L<sup>−1</sup> H<sub>2</sub>SO<sub>4</sub>. It can be seen from the figure that the hydrogen evolution overpotential of the TiVCT<sub>x</sub> nanosheets obtained after exfoliation at 10 mA cm<sup>−2</sup> is 583 mV, while the hydrogen evolution overpotential of TiVCT<sub>x</sub>@NF after modification is 151 mV, which is close to that of the platinum–carbon electrode (33 mV). The hydrogen evolution overpotential of NF at 10 mA cm<sup>−2</sup> is 261 mV, indicating that the hydrogen evolution catalytic activity of NF is stronger than that of TiVCT<sub>x</sub>, and the hydrogen evolution catalytic activity is further improved after the combination of TiVCT<sub>x</sub> and NF. TiVCT<sub>x</sub>@NF can be selected as a candidate for excellent hydrogen evolution catalyst materials.

The Tafel slope reveals the rate-determining steps of the hydrogen evolution catalytic reaction. Generally, when the Tafel slope reaches 30 mV, 40 mV or 120 mV, the rate-determining step of the hydrogen evolution catalytic reaction is identified as a Tafel, Heyrovsky or Volmer step, respectively. To understand the kinetics of the hydrogen evolution catalytic reaction of the hybrid TiVCT<sub>x</sub>@NF in the HER, the Tafel slope was used to reveal its reaction rate-determining steps.<sup>27</sup> Fig. 7(b) shows the Tafel slope curves of the four samples in 0.5 mol L<sup>−1</sup> H<sub>2</sub>SO<sub>4</sub>. It can be seen that the Tafel slopes of TiVCT<sub>x</sub>, NF, TiVCT<sub>x</sub>@NF and commercial platinum–carbon are 213 mV dec<sup>−1</sup>, 180 mV dec<sup>−1</sup>, 116 mV dec<sup>−1</sup> and 29 mV dec<sup>−1</sup>, respectively. The electrochemical test results show that the water splitting of the hybrid TiVCT<sub>x</sub>@NF in the hydrogen evolution catalytic process is based on the Volmer–Heyrovsky reaction mechanism,<sup>28</sup> which involves the rapid hydrogen ion adsorption Volmer reaction ( $\text{H}_3\text{O}^+ + \text{e}^- \rightarrow \text{H}_{\text{ads}} + \text{H}_2\text{O}$ ) and the slow hydrogen desorption Heyrovsky reaction ( $\text{H}_{\text{ads}} + \text{H}_3\text{O}^+ + \text{e}^- \rightarrow \text{H}_2 + \text{H}_2\text{O}$ ). Previous

Fig. 4 (a and b) SEM images of  $\text{TiVCT}_x\text{@NF}$ . (c) Elemental mapping images of  $\text{TiVCT}_x\text{@NF}$ .

studies have shown that the active site of the HER is generally the  $-\text{OH}$  group, and the two basic steps of water splitting are as follows: (1)  $\text{H}_3\text{O}^+$  ions are first adsorbed on the  $-\text{OH}$  group and then combined with electrons to generate a hydrogen atom. (2) The hydrogen atom generated in step 1 combines with an  $\text{H}_3\text{O}^+$  ion and an electron to generate  $\text{H}_2$ . The hydrogen desorption process in step 2 is the rate-determining step of the hydrogen evolution catalytic reaction. In addition, other scholars have reported the excellent electrochemical performance of MXene electrodes, as shown in Fig. 7(c) and (d); with the same electrolyte conditions, the  $\text{TiVCT}_x\text{@NF}$  electrodes are superior to MXene electrodes ( $\text{Ti}_3\text{C}_2\text{T}_x$ ,<sup>29</sup>  $\text{RuS}_A\text{-Ti}_3\text{C}_2\text{T}_x$  (ref. 30) and  $\text{Mo}_2\text{TiC}_2\text{T}_x\text{@NF}$ <sup>31</sup>).

Furthermore, electrochemical impedance spectroscopy (EIS) was used to reveal the electron transfer kinetics of  $\text{TiVCT}_x\text{@NF}$  during the hydrogen evolution reaction. Fig. 8(a) presents a Nyquist plot of the four samples. In the Nyquist

diagram, the impedance value represents the resistance encountered in the transfer of charges in the HER, and the smaller the arc radius, the smaller the impedance value of the test sample, indicating that the hydrogen evolution catalytic reaction is more likely to occur. The size of the semicircle is related to the electrode surface properties and determines the size of the charge transfer resistance ( $R_{\text{ct}}$ ). It is obvious that the impedance value of the hybrid  $\text{TiVCT}_x\text{@NF}$  is significantly lower than that of the  $\text{TiVCT}_x$  MXene. The electrochemical impedance spectrum is fitted using the Z-view software; the fitted resistance circuit diagram is shown in Fig. 8(b) and the related resistance parameter fitting results are presented in Table 1.  $R_1$  represents the equivalent series resistance (ESR), which consists of three parts: the ionic resistance of the electrolyte, the resistance inside the active material and the current collector, and the interfacial contact resistance between the electrode and the electrolyte.  $R_2$  represents the

Fig. 5 XPS spectra of the TiVCT<sub>x</sub> MXene: (a) the full spectrum, (b) Ti 2p, (c) C 1s, (d) F 1s, (e) V 2p and O 1s.

diffusion resistance, which refers to the resistance caused by the transport of ions in a thin layer, which is related to the current changes, concentration changes, and electrode

materials.  $R_3$  represents the charge transfer resistance ( $R_{ct}$ ). As shown in Table 1, the fitted resistance of TiVCT<sub>x</sub>@NF is smaller than that of the other two electrode materials, and the

Fig. 6 Cyclic voltammetry curves of (a) TiVCT<sub>x</sub>@NF, (c) TiVCT<sub>x</sub> and (e) commercial Pt/C recorded from -6 to 94 mV vs. RHE at scan rates of 20, 40, 60, 80, 100 and 120 mV s<sup>-1</sup>. Estimated double-layer capacitances (C<sub>dl</sub>) of (b) TiVCT<sub>x</sub>@NF, (d) TiVCT<sub>x</sub> and (f) commercial Pt/C.

$R_3$  of TiVCT<sub>x</sub>@NF is only 186.5  $\Omega$ . This indicates that the TiVCT<sub>x</sub>@NF electrode system has a smaller internal resistance and larger electroactive surface, and it is easier for ions to

penetrate between the sheets of the electrode material. These results indicate that TiVCT<sub>x</sub>@NF has better electrochemical performance.

Fig. 7 (a) Polarization curves and (b) corresponding Tafel plots of TiVCT<sub>x</sub>, TiVCT<sub>x</sub>@NF, NF and commercial Pt/C at a scan rate of 10 mV s<sup>-1</sup> in a 0.5 M H<sub>2</sub>SO<sub>4</sub> solution. (c) Polarization curves and (d) corresponding Tafel plots of Ti<sub>3</sub>C<sub>2</sub>Tx, TiVCT<sub>x</sub>@NF, RuSA-Ti<sub>3</sub>C<sub>2</sub>Tx and Mo<sub>2</sub>TiC<sub>2</sub>Tx@NF at a scan rate of 10 mV s<sup>-1</sup> in a 0.5 M H<sub>2</sub>SO<sub>4</sub> solution.

To evaluate the comprehensive performance of a hydrogen evolution catalyst, it is necessary not only to consider the catalytic activity of the hydrogen evolution reaction but also to test its stability. In order to examine the catalytic stability of the

TiVCT<sub>x</sub>@NF composites in 0.5 mol L<sup>-1</sup> H<sub>2</sub>SO<sub>4</sub>, long-term CV cycling tests for 1000 cycles were carried out. As shown in Fig. 9(a), the time-dependent electrical density curve remains almost unchanged for the HER after 1000 test cycles. As shown

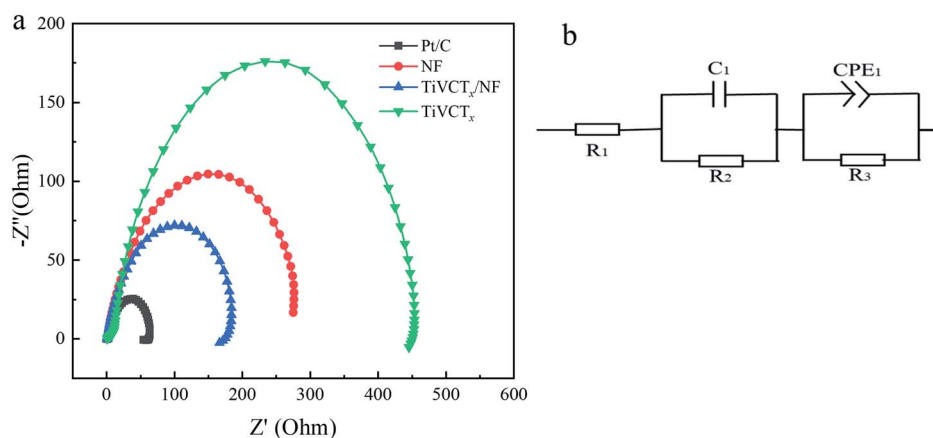

Fig. 8 (a) Electrochemical impedance spectra of Pt/C, NF, TiVCT<sub>x</sub> and TiVCT<sub>x</sub>@NF for the electrocatalytic HER at an overpotential of open-circuit potential. (b) Equivalent circuit diagram of the TiVCT<sub>x</sub>@NF composites.

Table 1 EIS fitting parameters of the TiVCT<sub>x</sub>, NF and TiVCT<sub>x</sub>@NF electrodes

Working electrode	$R_1$	$R_2$	$R_3$	$C_1$	$CPE_1-T$	$CPE_2-T$
TiVCT <sub>x</sub>	15.62	115.1	2334	$1.02 \times 10^{-5}$	$6.39 \times 10^{-6}$	0.8533
NF	15.34	9.447	442.8	$2.89 \times 10^{-5}$	$5.17 \times 10^{-6}$	0.8693
TiVCT <sub>x</sub> @NF	1.33	3.695	186.5	0.0079	0.0021	0.8247

Fig. 9 (a) Polarization curves of TiVCT<sub>x</sub>@NF initially and after 1000 CV cycles. (b) Current density versus time for TiVCT<sub>x</sub>@NF at a 150 mV potential.

in Fig. 9(b), the catalytic activity for hydrogen evolution of TiVCT<sub>x</sub>@NF remains almost unchanged at 0.15 V for 12 h. From the above results, it can be seen that the hybrid TiVCT<sub>x</sub>@NF exhibits excellent HER catalytic activity and good stability during long-term electrolysis, indicating that TiVCT<sub>x</sub>@NF is a highly stable electrocatalyst for HER.

## 4. Conclusion

In summary, TiVCT<sub>x</sub>@NF was successfully prepared using the annealing method. Selecting a typical three-electrode system, the comprehensive electrochemical performance of TiVCT<sub>x</sub>@NF was tested. The experimental results show that the composite TiVCT<sub>x</sub>@NF exhibits excellent electrochemical properties with a low overpotential of 151 mV at 10 mA cm<sup>-2</sup> and a small Tafel slope of 116 mV dec<sup>-1</sup>. In a 0.5 M H<sub>2</sub>SO<sub>4</sub> solution, TiVCT<sub>x</sub>@NF exhibits excellent HER catalytic activity after 1000 test cycles and long-term stability over 12 h. Compared to the TiVCT<sub>x</sub> MXene, TiVCT<sub>x</sub>@NF has more active sites and less resistance encountered in the transfer of charges in the HER. Based on these excellent electrochemical properties, TiVCT<sub>x</sub>@NF is expected to be applied as an electrocatalytically active catalyst for water splitting.
