Improved catalytic activity and bactericidal behavior of novel chitosan/V₂O₅ co-doped in tin-oxide quantum dots

 Muhammad Ikram,^a Iram Shahzadi,^b Ali Haider,^c Shaukat Hayat,^d Junaid Haider,^e Anwar Ul-Hamid,^f Anum Shahzadi,^g Walid Nabgan,^h Sobia Dilpazirⁱ and Salamat Ali^d

The novel V₂O₅/chitosan (CS) co-doped tin oxide (SnO₂) quantum dots (QDs) were synthesized *via* co-precipitation technique. The optical, structural, morphological, and catalytic properties of the concerned specimens were examined by UV-Vis, PL, FTIR, X-ray diffraction, HR-TEM, and EDS. Structural analysis through XRD confirmed the tetragonal structure of SnO₂; meanwhile, HR-TEM measurements unveiled quantum dot morphology. Rotational and vibrational modes related to functional groups of (O–H, C–H, Sn–O, and Sn–O–Sn) have been assessed with FTIR spectra. Through UV-Vis spectroscopy, a reduction in band-gap (4.39 eV to 3.98 eV) and redshift in co-doped spectra of SnO₂ were identified. Both CS/SnO₂ and V₂O₅-doped CS@SnO₂ showed promising catalytic activity in all media. Meanwhile, CS/SnO₂ showed higher activity for use in hospital and industrial dye degradation in comparison to dopant-free Ch/SnO₂. For V₂O₅/CS@SnO₂ QDs, inhibition domains of G^{–ve} were significantly confirmed as 1.40–4.15 mm and 1.85–5.45 mm; meanwhile, for G^{+ve} were noticed as 2.05–4.15 mm and 2.40–5.35 mm at least and maximum concentrations, correspondingly. These findings demonstrate the efficient role of V₂O₅/CS@SnO₂ QDs towards industrial dye degradation and antimicrobial activity.

1. Introduction

Scientists' emphasis has changed progressively toward a clean and green environment in recent years due to extensive urbanization and industrialization. Exposure to contaminants such as oils, leather, paper pulp, dyes, metal ions, and other pollutants that are dumped into water bodies daily in today's heavily industrialized civilizations seems to have become unavoidable for people all over the world.^{1,2} In order to control

pollutants that threaten human safety and health, it is necessary to make more optimal and cost-effective use of current resources. Water contamination is one of the most serious threats to all living things.³ A small amount (0.02%) of the total water on the planet is suitable for human consumption. Unluckily, this small amount is under tremendous threat of contamination. A report published in May 2018 by the Pakistan Council of Research in Water Resources stated that by 2025, Pakistan would have little or no clean water.⁴ From recent studies, clean drinking water for this country is available to less than 20% of its population. Inadvertently, the remaining 80% of the community absorbs polluted water, primarily due to sewerage, but also due to pesticides, fertilizers, and industrial drainage that are discharged into water bodies without proper treatment of excreting hazardous compounds, resulting in severe contamination of drinking water.^{5–7} Aside from the deaths caused by drinking polluted water, there have been several cases of tooth and bone disease, hepatitis, diarrhea, cancers, dysentery and typhoid, and other aquatic illnesses resulting from drinking contaminated water.⁶

A variety of traditional approaches have been utilized, such as coagulation,⁸ evaporation,⁹ biological treatment,¹⁰ filtration, advanced oxidation process,¹¹ electrochemical, photocatalysis,¹² adsorption,¹³ and ion exchange¹⁴ for the elimination of these contaminants (color dyes) from waste-water.¹⁵ The main issue is that these traditional methods are costly as applied on large

scales. Regarding this, researchers recently adopted various adsorbents, for example, zeolite, semiconductors, activated carbon, polymers, and carbon nanotube-based materials. The adsorption technique can be extensively utilized to degrade different reactive dyes in wastewater treatment.^{13,16–19} Proper dye treatment, including catalytic degradation and adsorption, is recommended for the removal of methylene blue (MB) dye to improve life quality. Adsorption is cost-effective; however, catalyst recovery is difficult and can result in hazardous compounds. Even while catalytic degradation is a little more costly, it is also rather simple and has the advantage of being recyclable.²⁰ Extensively used oxides semiconductor (CeO₂, TiO₂, NiO, ZnO, CuO, SnO₂, CaO, and Fe₂O₃) has been reported as novel catalysts for organic dye degradation due to their toxin-free nature, chemical stability, high activity, as well as cost benefits.²¹ Among all of the aforementioned, SnO₂ is especially beneficial due to the fact that it is an n-type semiconductor with a large band gap (E_g) ranging from 3.6–4.37 eV.²² SnO₂ possessing variety of potential applications in different fields such as photocatalysis, rechargeable, electrodes, *etc.*²³

Chitosan (CS)-doped QDs are currently gaining tremendous attention in catalytic MB dye degradation because of their low immunogenicity, biodegradability, cost-effective biocompatibility, and non-toxic nature.^{24,25} Chitosan is a semi-crystalline polymer with strong hydrogen bonding between inter and intra-molecules. Chitosan is a biocompatible, stable, biodegradable, safe, and bioactive polysaccharide. Chitosan is easily possible for chemical modification due to the presence of hydroxyl (O–H) and reactive amino groups.²⁵ Catalyst immobilization on the polymer surface may provide an additional benefit as high adsorption capacity, increased catalytic activity, and high reusability.¹² Chitosan is a promising candidate (as a host polymer) for chitosan-based QDs synthesis due to the abovementioned characteristics.

Furthermore, few attempts have been conducted with the doping of SnO₂ QDs by transition metals ions (TMI), including cobalt, nickel, chromium, magnesium, and vanadium (V₂O₅), aiming to boost SnO₂ photo response from ultra-violet to visible-region.^{26,27} Specifically, V₂O₅ could be easily incorporated into SnO₂ QDs as an ionic radius of (V^{5+}/Sn^{4+}) = 0.59/0.69 Å, which is smaller than un-doped Sn⁴⁺ ion.²⁸ The V₂O₅ doped SnO₂ catalytic activity is expected to demonstrate promising activity due to its capacity to gain/lose oxygen. Additionally, adding different vanadium amounts in SnO₂ may be efficiently extended SnO₂ absorption edge in visible region; as a result, catalytic activity increases.²⁸ Therefore, loading of V₂O₅ into host SnO₂ is tried in the present work.

Despite its thermal stability and low reactivity, SnO₂ has received little attention in antibacterial and catalytic degradation applications. To efficiently boost the uses of SnO₂ nanorods (NRs) in this affection, V₂O₅ and chitosan have been incorporated into SnO₂ lattice. In current work, we have synthesized 2 and 4% V₂O₅/CS co-doped SnO₂ QDs using a cost-effective and ecofriendly co-precipitation process and various characterization tools employed for detailed analysis (TEM, XRD, EDS, FTIR, PL, and UV).

2. Experimental section

2.1 Materials

Stannous chloride dihydrate (SnCl₂·2H₂O, 98%), chitosan (C₆H₁₁NO₄)_n, sodium hydroxide (NaOH, 98%), and vanadium oxide (V₂O₅, 99.6%), sodium borohydride (NaBH₄, 99.5%) have been procured from Sigma-Aldrich.

2.2 Synthesis of tin oxide

Tin oxide (SnO₂) was synthesized *via* a doping co-precipitation approach by stirring 0.5 M SnCl₂·2H₂O in deionized water (100 mL) for 40 min at 80 °C. Dropwise addition of 0.5 M of NaOH solution was used to maintain the pH 12 of the stirred solution. After 2 hours of heating, the solution was collected, centrifuged at 7100 rpm and washed several times for ~10 min. Consequently, the pellet obtained from centrifuged solution was heated (90 °C, 10 hours). Finally, SnO₂ nanomaterials (NPs) were annealed at 350 °C for 120 min and ground to attain fine powder, as unveiled in Fig. 1.²⁹

2.3 Synthesis of vanadium/chitosan co-doped tin oxide

Firstly, 0.564 g of chitosan (CS) was added in 40 mL of deionized water under continual magnetic stirring (30 min, 80 °C) to form a homogeneous solution. Afterward, this homogeneous solution was incorporated in SnO₂ solution, as prepared above. Secondly, various amounts (2%, 4%) of V₂O₅ were poured into chitosan-doped SnO₂ solution and stirred for 30 min. Adjusted the pH 12 using NaOH, harvested the synthesized product by centrifugation, then calcined at 350 °C for 120 min to prepare the nanocomposites powder. These synthesized samples are represented as SnO₂, CS@SnO₂, and V₂O₅ (2 and 4%), where 2% and 4% correspond to different concentrations of V₂O₅ doped in a fixed concentration of CS@SnO₂, as revealed in Fig. 1.

2.4 Isolation and identification of *S. aureus* and *E. coli*

Mastitis-positive sheep milk samples have been collected from different farms and veterinary clinics in Punjab, Pakistan, and cultured on 5% sheep blood agar (SBA). Cultured specimen plates were incubated at ~37 °C for 12 hours. Segregated bacterial isolates were purified by streaking in triplets on MacConkey and mannitol salt agar (MCA and MSA), correspondingly at ~pH 7. Morphological studies (Gram staining) and biochemical analysis (coagulase and catalase tests) were employed to identify isolated colonies.

2.5 Antimicrobial activity

As concerned, specimens were deployed to assess bactericidal action against Gram –ve and Gram +ve bacteria *via* agar well diffusion procedure at cultured Petri plates swabbed with 0.5 McFarland bacterial growth.³⁰ A sterile cork borer was utilized to prepare wells having 6 mm diameter on MCA and MSA plates; meanwhile, aseptically prepared wells were filled with varying concentrations of pristine and co-doped SnO₂ (0.5 and 1.0 mg/0.05 mL) as the minimum and maximum doses, respectively, in

Fig. 1 Schematic illustration of preparation and structure of V₂O₅/chitosan co-doped SnO₂.

contrast with ciprofloxacin (0.005 mg/0.05 mL) and DI water (0.055 mL) as positive and negative controls, respectively. Antimicrobial efficacy was determined through the Vernier caliper by measuring inhibition areas in millimeters (mm) after overnight incubation at $\sim 37^\circ\text{C}$.³¹

2.6 Catalytic activity

The MB dye has been employed to study the catalytic activity (CA) of pure SnO₂, CS@SnO₂, and co-doped SnO₂ QDs in a solution containing a specific amount of NaBH₄ (800 μL , 400 μL) as a reducing agent, respectively. As pure and co-doped QDs

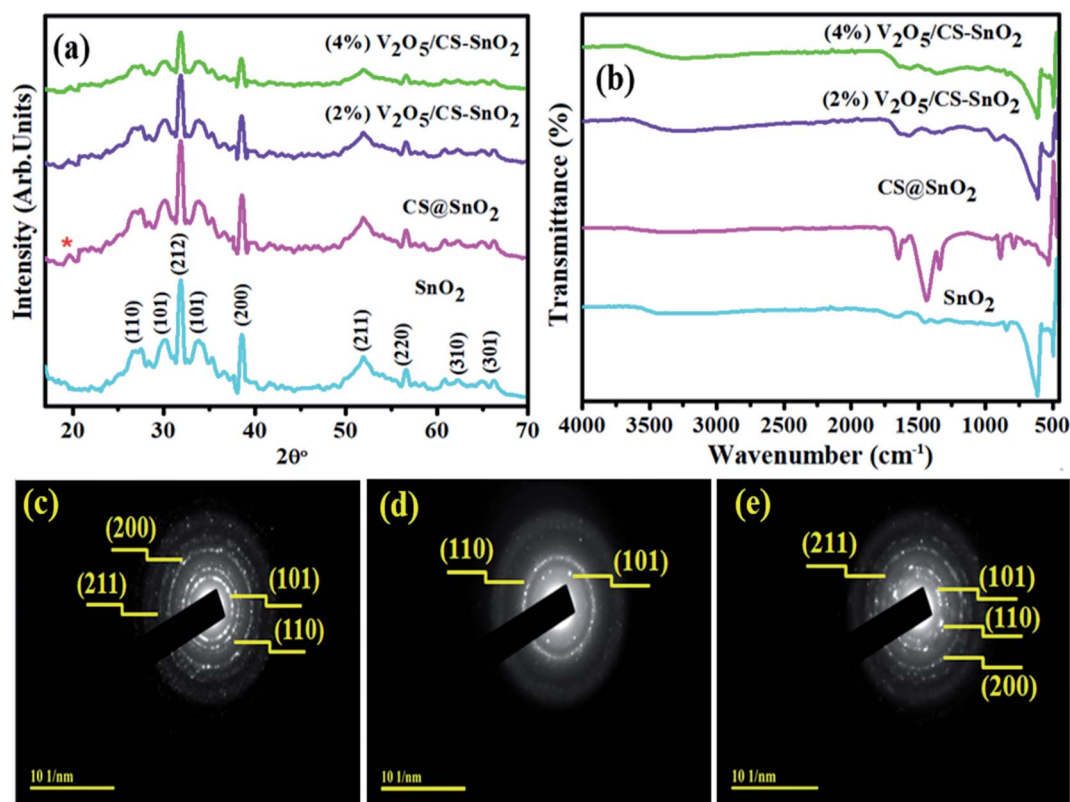

Fig. 2 Diffraction pattern (a) FT-IR spectra (b) of SnO₂, CS/SnO₂ and (2, 4%) V₂O₅/SnO₂/CS, respectively, meanwhile (c–e), SAED patterns of pristine, CS/SnO₂ and co-doped SnO₂.

added to a solution with MB and NaBH₄, a promising deterioration was noticed. UV-vis absorption measurements ranging from 200 to 800 nm were used to confirm considerable dye degradation. Dye degradation is influenced by particle size; smaller particles have a higher surface-volume ratio, resulting in improved catalytic activity.^{12,32}

3. Results and discussion

The synthesized CS@SnO₂, and (2, 4%) V₂O₅/CS-doped and undoped SnO₂ quantum dots (QDs) have been characterized utilizing the XRD technique and corresponding results as shown in Fig. 2a. The seven diffraction peaks with 2θ° values of 26.74°, 31.64°, 33.21°, 38.12°, 51.9°, 56.64°, 62.02°, and 65.24° corresponding to pristine SnO₂ crystal planes of (110), (212), (101), (200), (211), (220), (310), and (301), respectively and confirming SnO₂ tetragonal structure.³³ These analytical findings matched with the XRD data file of SnO₂ (JCPDS No. 41-1445).³⁴ Besides, additional diffracted peaks at 2θ° = 30° (101) and 45° (200) crystal planes indicated the presence of SnO (JCPDS-01-085-0423).³⁵ For CS-doped SnO₂ sample, a new emerging peak at ~19.2° was found (marked by a red star).³⁶ However, adding V₂O₅ (2 and 4%) into CS@SnO₂ QDs, no extra peak related to V₂O₅ was noticed, but peak intensity was reduced compared to undoped SnO₂. This preliminary confirms successfully doping

(2 and 4%) V₂O₅ into CS@SnO₂. A decrease in the intensity of the peak implies a decrease in the crystallinity of the material. Average crystallite size *D* for undoped and co-doped SnO₂ was calculated with the Debye–Scherer formula and found to be 7.52, 9.18, 11.71, and 12.63 nm, respectively, might be close to earlier reported work.

$$D = \frac{k\lambda}{\beta \cos \theta}$$

where *D* denotes the crystal size (nm), and *k* is constant relating to the crystallite shapes (0.9), wavelength for X-rays is λ = 1.54056 Å, θ is scattering angle (in radians), β is the full peak width at half maximum (FWHM) has the highest intensity (212),

Fig. 2b demonstrated the FTIR spectrum of pristine SnO₂ and (2, 4%) V₂O₅/CS co-doped SnO₂, correspondingly ranging from 500 to 4000 cm⁻¹. The broadband 3516 cm⁻¹ and the band 1649 cm⁻¹ identified in the synthesized specimens are ascribed to stretching of O–H groups, which may be caused by adsorbed water molecules vibration.³⁷ The sharp peak at 618 cm⁻¹ corresponds to the SnO₂ framework vibrations; meanwhile,³⁸ the peak area ~1422 cm⁻¹ unveiled bending vibrations of CH₂.^{37,39,40} A small peak flexing found around 493 cm⁻¹ is inclined to Sn–O stretching vibration. Similarly, a new peak for CS@SnO₂ is found at ~1320 cm⁻¹ due to secondary and tertiary amide functional groups. After (2%) V₂O₅ incorporation in CS/

Fig. 3 UV-vis (a), band gap energy (b), PL spectra (c) of bare and doped SnO₂, respectively.

SnO₂ QDs, a new peak appeared at 928 cm⁻¹ for the vanadium doped contents.⁴¹ The vibrations in co-doped spectra and changes in peak intensities again supported the substitution of V₂O₅/CS into SnO₂ successfully. SAED (Selected Area

Diffraction) images of bare SnO₂, CS@SnO₂, and V₂O₅/CS co-doped SnO₂ samples are expressed in Fig. 2c–e. With diffraction planes, images of concerned specimens were indexed as (101), (110), (211), and (220), respectively, and these circular

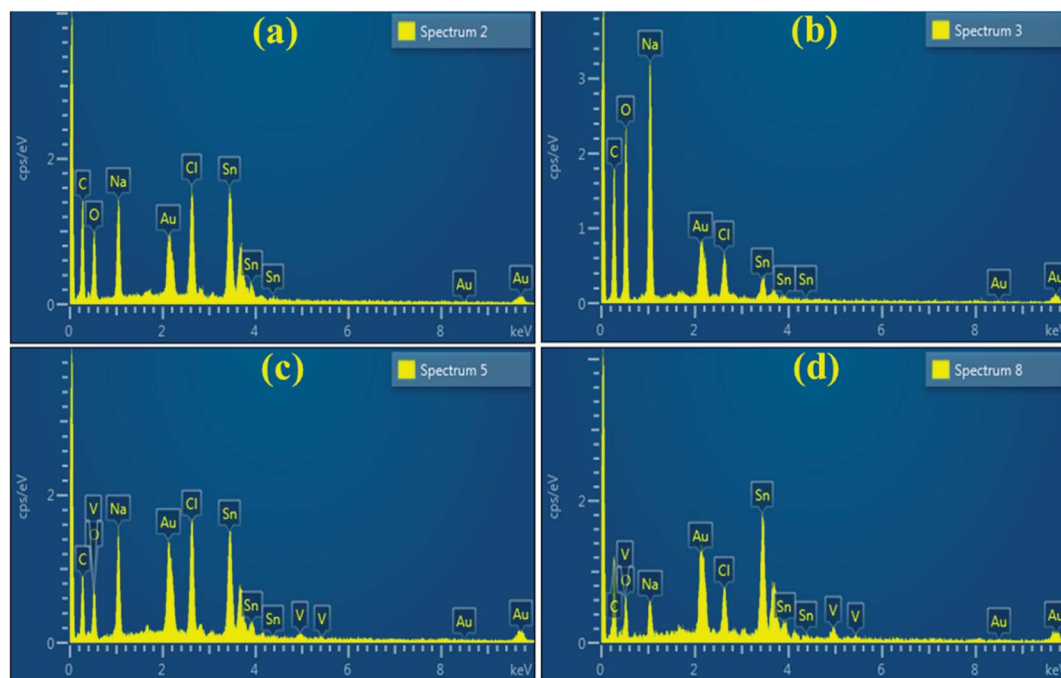

Fig. 4 EDS profiles of SnO₂ (a), CS@SnO₂ (b), and 2, 4% V₂O₅/CS-doped SnO₂ (c, d) samples, respectively.

rings with bright spots demonstrated the polycrystalline nature of SnO₂. With the incorporation of V₂O₅ and CS, the crystallinity of concerned samples was enhanced, confirmed by XRD findings, which show SnO₂ tetragonal structure.

UV-vis spectra have been recorded to examine optical absorption features and the influence of CS and V₂O₅ on SnO₂ in absorption wavelengths 300–675 nm. Characteristics peak for SnO₂ was stationed ~285 nm as unveiled in Fig. 3a and compared with pristine SnO₂, slight redshift for CS@SnO₂ QDs

was occurred meanwhile, upon adding of (2, 4%) V₂O₅, sharp redshift was noticed referring to further band gap (E_g) decrease.^{42–44} Additionally, upon vanadium doping, the absorption improved as the concentration increased from 2 to 4%. This absorption may be ascribed to the sp-d exchange interaction between band electron and the localized d-electron of V⁵⁺ ions substituting on Sn⁴⁺ ions.⁴⁵ The E_g values were determined through the Tauc plot. Meanwhile, graphs for SnO₂, CS@SnO₂, and co-doped SnO₂ QDs were displayed for ($\alpha h\nu$)

Fig. 6 Interlayer d -spacing images of SnO₂ (a), CS/SnO₂ (b), and (2, 4%) V₂O₅/SnO₂/CS (c, d), respectively, d spacing scale bar 5 nm.

Table 1 Antibacterial efficiency of SnO₂, CS@SnO₂, and co-doped SnO₂

Samples	Inhibition zone ^a (mm)		Inhibition zone ^b (mm)	
	0.5 mg/50 μ L	1.0 mg/50 μ L	0.5 mg/50 μ L	1.0 mg/50 μ L
SnO ₂		0.80		
CS@SnO ₂	1.40	1.85	2.05	2.40
(2%) V ₂ O ₅ /CS@ SnO ₂	3.35	3.95	2.55	3.35
(4%) V ₂ O ₅ /CS@ SnO ₂	4.15	5.45	4.15	5.35

DIW	0	0	0	

^a Measurement of inhibition domains against G –ve. ^b Inhibition areas (mm) for G +ve.

versus ($h\nu$) as divulged (Fig. 3b). The E_g of SnO₂ sample was calculated as 4.39 eV, which agreed with the values reported by Zhenxing Li *et al.*, meanwhile, after CS and V₂O₅ dopants, E_g decreased up to 3.98, 4.17, and 4.29 eV, respectively, for CS@SnO₂ and co-doped SnO₂. This reduction in E_g may be s-d and p-d exchange interaction, giving rise to +ve and -ve correction to valence and conduction band edges, respectively, and resulting in a narrowing in E_g .⁴⁵

To investigate the optical characteristics, energy levels and quantum confinement phenomena of semiconducting nanocomposites and the presence of possible defects caused by dopants and surfactants, PL spectra were obtained ranging from 420 to 600 nm with an excitation wavelength of 325 nm under an ambient condition. Furthermore, emission can be ascribed to un-resolved states as pumping promotes excitons to attain two or more than two \bar{e} - h^+ pairs because of the coulomb effect, which increases photoemission. Also, lower emission corresponding results demonstrate a less intense band and indicate lower \bar{e} - h^+ carrier recombination.⁴⁶ Fig. 3c demonstrated the PL spectra of SnO₂, CS@SnO₂, and (2, 4%) V₂O₅/CS co-doped SnO₂ QDs, respectively. The concerned samples revealed a visible emission centered about \sim 434 nm. This blue emission was noticed due to electron transfer from ionized oxygen to the valence band.^{47,48} However, upon (2 and 4%) V₂O₅ doping in CS@SnO₂, visible emission peak intensity (439 nm) becomes lower than pure SnO₂. The oxygen transfer from the V₂O₅ lattice to oxygen vacancies in the SnO₂ lattice may explain this.^{48,49} The pentavalent character of the V⁵⁺ ions loaded in vanadium-doped SnO₂ lattice allows oxygen to flow from V₂O₅ sites, resulting in a decrease in oxygen vacancy for vanadium-infused SnO₂ lattice.⁴⁹

Energy dispersive X-ray spectroscopy (EDS) has been carried out for element content confirmation and additional features of as-prepared SnO₂, CS@SnO₂, and (2, 4%) V₂O₅/CS-doped SnO₂ (Fig. 4a-d). EDS analysis unveiled the presence of Sn, O, C, Cl, and V peaks which described that the concerned nanoparticles are pure. Impurity peaks such as Na and Cl were detected in all synthesized materials that may come from NaOH solution used to retain pH and Cl occurred during the synthesis of SnO₂ from SnCl₂·H₂O, respectively. Minor trace of Au peak instigated from the coating and holder utilized for the EDS observation.⁵⁰ This showed the successful formation of SnO₂ and co-doped SnO₂ samples.

HRTEM images in Fig. 5(a-d) show the morphological features from SnO₂ to 4% V₂O₅/CS co-doped SnO₂, respectively. High-resolution TEM micrographs of synthesized samples revealed that the material has a 0D nature and confirmed the evolution of QDs, as illustrated in Fig. 5(a-d). QDs of CS-doped SnO₂ are present in spherical structure (Fig. 5b) while in the presence of 2% vanadium QDs in the porous structure. The morphologies of QDs confirm that particle size increase with V₂O₅ incorporation into SnO₂ QDs. Particle sizes of SnO₂, CS/SnO₂, and (2, 4%) CS/V₂O₅/SnO₂ QDs were measured through TEM and found to be 9.21, 11.37, 13.86, 15.14 and 17.45 nm, respectively which revealed a significant increase from 9.21 to 17.45 nm. HR-TEM micrograph indicated the slight agglomeration after 4% vanadium doping, as depicted in Fig. 5d.

Table 2 Literature comparison of dye degradation, antibacterial activity, particle sizes, crystallite sizes and surface area with present work

Nano-catalyst	Synthesis process	Dye degradation performance	Antibacterial activity	Particle size (μm)	Crystallite size (nm)	Surface area (m ² g ⁻¹)	Ref.
Ce:SnO ₂ NPs	Sol-gel method	~67.83% in 100 minutes against methyl orange	—	0.1–0.3	6	56.33	63
Mn:SnO ₂ NPs	Co-precipitation	92% in 180 minutes for naphthol blue black	Strong activity showed in response to <i>S. typhi</i> and <i>S. aureus</i> on higher concentration	—	—	7.73	64
Cur-Ag-SnO ₂ NPs	Co-precipitation approach	41.23% in 150 minutes by higher doping of silver against rose Bengal (RB)	11 mm and 14 mm for <i>C. albicans</i> and <i>A. flavus</i> for higher concentration	0.1–4.0	21.04	21.39	65
Peel extract-doped SnO ₂ NPs	Green synthesis approach	100% in 180 minutes on higher doping of extract into SnO ₂ , against MB:MO:RhB	—	4–8 nm	12.1	7.6	66
CS/SnO ₂	Co-precipitation	Maximum degradation occurs (92% and 79%) within 100 minutes against MO and RhB	—	11 nm	6.7	89.2	67
CS/V ₂ O ₅ /SnO ₂ QDs	Co-precipitation	99.89% in acidic medium against MB	5.45 mm and 5.35 mm inhibition zone measured for <i>E. coli</i> and <i>S. aureus</i> on very low concentration	17.45 nm	12.63 nm	—	Present work

Meanwhile, d-spacing of pure and doped samples was calculated, and these values (0.27, 0.29, 0.34 and 0.37 nm) are well-matched with XRD results (Fig. 6a–d)

The *in vitro* bactericidal potency for un-doped SnO₂, CS@SnO₂, and (2, 4%) V₂O₅/CS-doped SnO₂ QDs was evaluated *via* measuring inhibition areas utilizing a well diffusion procedure against *Escherichia coli* (*E. coli*) and *Staphylococcus aureus* (*S. aureus*), as revealed in Table 1. According to the findings, the concentration and inhibition zones (mm) were synergistic with each other. For V₂O₅/CS@SnO₂ QDs, inhibition domains of G^{-ve} were significantly confirmed as (1.40–4.15 mm) and (1.85–5.45 mm); meanwhile, for G^{+ve} were noticed as (2.05–4.15 mm) and (2.40–5.35 mm) at least and maximum concentrations, correspondingly. Broadly, null activity was measured for SnO₂ to *S. aureus* at a minimum and maximum concentration. Compared to deionized water (DI) (0 mm), ciprofloxacin presented 5.35- and 6.10 mm inhibition domains against *E. coli* and *S. aureus*, respectively. The antibacterial activity is reviewed in light of the previous findings presented in Table 2.

The exact mechanism of the action of the SnO₂ QDs against different microbial strains (*E. coli* and *S. aureus*) is currently unknown. However, a number of mechanisms against both these bacteria have been recommended for metal oxide QDs, for example, decomposition of QDs, smaller particle size or large surface area of QDs, electrostatic interaction of QDs to the microorganisms cell wall, and reactive oxygen species (ROS) formation.^{51–55} According to the findings of the current investigation, one possible explanation for the antibacterial activity of SnO₂ QDs is the accumulation of QDs on the surface of the bacterial cell membrane. As a consequence of QDs, ROS is produced, which interacts with the cell membrane and affects the bacterium's membrane permeability and respiratory system, ultimately leading in cell death of the bacteria.^{51,56–58} For instant, Khan *et al.* proposed that the release of Co²⁺ and Sn⁴⁺ may be cause for damaging mitochondria and bacterial DNA, which inactivate the bacterial enzyme and eventually lead to cell death (Fig. 7).⁵⁹

Fig. 7 Bactericidal mechanism exhibited by the prepared Pristine and co-doped SnO₂.

3.1 Catalytic activity

The catalytic activity of undoped, CS@SnO₂ and V₂O₅/CS doped SnO₂ QDs was carried out for the methylene blue (MB) degradation acts as an oxidizer in the manifestation of reducer NaBH₄ (Fig. 9). In current work, the as-synthesized specimens act as a catalyst. This activity completely relies on the concentration of the catalyst as it strengthens the dye degradation because the catalyst always minimizes the activation energy of a chemical reaction.³² For the catalysis, 400 μ L of sodium borohydride (NaBH₄) was added to 3 mL aqueous MB in a quartz cell. Catalytic activity usually depends on the surface area, crystallinity, and morphology of QDs. In general, the catalyst having a wide surface area has shown higher catalytic effectiveness because the catalyst may provide more active sites,^{60,61} and the pH of the solution has a significant impact on degradation efficiency. In acidic media, catalytic activity was higher, which might be assigned to increased H⁺ ions production absorbed by the surface of the nanostructure. The number of hydroxyl groups in NaOH (basic medium) increases, causing reduced products to be oxidized and catalytic activity to be diminished. The dye degradation of (MB) was investigated using UV-vis spectroscopy during the catalysis process of pure and co-

doped QDs. The SnO₂, CS@SnO₂, V₂O₅/CS doped SnO₂ showed degradation of 50.29, 98.81, 58.87 and 54.87% in neutral medium (pH = 7), 48.99, 99.89, 59.45, and 47.25% in acidic medium (pH = 4), and 36.94, 99.3, 92.46, and 53.73% in basic medium (pH = 12), respectively as express in Fig. 8a, b, c. Both trapping and de-trapping for the charge carrier divulged by V₂O₅/Ch co-doped SnO₂ catalyst may be accounted to its electronic configuration. V⁵⁺ possessing completely 's' and 'd' orbital that are in stable form. As V trapping the electron (e⁻)/ holes the stability may be disturbed and V dopant conquers the stable state *via* detrapping it and this form of trapping is termed as shallow trapping. Trapping and de-trapping boost up interfacial charge transfer phenomena leading to the excess generation of super oxide and hydroxyl radicals. Therefore it can be concluded that the prerequisite condition for the dopant to be effective lies in its optimum concentration which facilitate the formation of appropriate dopant energy levels and surface states for the smooth migration of charge carriers.⁶² A comparison of degradation rate (%) over the previously reported nanomaterials is displayed in Table 2.

As depicted in Fig. 10a–c, XPS was used to determine the chemical structure of V₂O₅/Ch co-doped SnO₂ to validate V₂O₅

Fig. 8 The catalytic activity of SnO₂, CS@SnO₂, and V₂O₅/CS-SnO₂ with vanadium ratio (2, 4%) neutral, acidic, and basic medium (a, b and c), respectively.

Fig. 9 Schematic illustration of catalysis of co-doped SnO₂.

doping. For doped material, the measured O 1s binding energy has a strong peak at 530.65 eV, which strongly corresponds to the value for SnO₂. The second peak at 531.8 eV may be attributed to an O-C bond⁶⁸ or to O²⁻ in oxygen-deficient regions, as

shown in Fig. 10(a).⁶⁹ Principal high Sn⁴⁺ 3d_{5/2} (486.2 eV) and Sn⁴⁺ 3d_{3/2} (494.6 eV) were attributed to SnO₂, proving its existence.⁷⁰ Moreover, the peaks of Sn²⁺ 3d_{5/2} and Sn²⁺ 3d_{3/2} were found in V₂O₅/Ch co-doped SnO₂ samples, indicating that Sn⁴⁺

Fig. 10 XPS spectra of CS@V₂O₅ co-doped SnO₂ (a) C 1s of SnO₂, (b) Sn 3d and (c) V 2p_{3/2}.

ions were partially reduced to Sn^{2+} during doping process, as shown in Fig. 10(b).⁷¹ The core level binding energies of the $\text{V}2\text{p}_{3/2}$ spectrum shown in Fig. 10c are split into two peaks at 517.40 eV and 515.80 eV, which correspond to V^{5+} and V^{4+} species, correspondingly.⁷²

4. Conclusion

In current study, we have effectively prepared pure SnO_2 and 2, 4% $\text{V}_2\text{O}_5/\text{CS}$ co-doped SnO_2 QDs for catalytic activity and bactericidal action using a co-precipitation approach. XRD analysis of synthesized samples confirmed that the tetragonal structure and crystallite size increased (7.52 to 12.63 nm) upon co-dopants in SnO_2 . The SnO_2 presence was confirmed through Sn–O stretching vibration in FTIR. The absorption increased upon doping; therefore, a reduction in band gap energy was observed from 4.39–4.29 eV with 4% $\text{V}_2\text{O}_5/\text{CS}$ doping in SnO_2 . HR-TEM and EDS analysis confirmed the formation of the quantum dots and the SnO_2 QDs. The results found to be synergistic with the concentration and inhibition zones (mm) identified. The $\text{CS}@\text{SnO}_2$ sample demonstrated promising degradation against MB dye in all three media (neutral, acidic, and basic) 98.81, 99.89, and 99.3%, respectively, compared to pristine and (2, 4%) $\text{V}_2\text{O}_5/\text{CS}$ co-doped SnO_2 . The current study $\text{V}_2\text{O}_5/\text{CS}$ co-doped SnO_2 showed good antibacterial and catalytic efficacy in treating industrially polluted wastewater and biomedical applications.

Conflicts of interest

Manuscript is free from conflicts of interest.

Acknowledgements

The authors thank HEC, Pakistan, for funding NRPU Project 20-17615.
