rsc.li/rsc-advances

A convenient and efficient annulation reaction has been developed for the general synthesis of dinitrile-substituted cyclopropanes in moderate to excellent yields. A variety of 2-arylacetonitriles and α -bromoennitriles were compatible under the standard conditions. The reaction was achieved through tandem Michael-type addition followed by intramolecular cyclization. The preliminary application of this method was confirmed by the synthesis of the 2,4-dioxo-3-azabicyclo[3.1.0]hexane scaffold.

Substituted cyclopropanes, as attractive structural units, are commonly found in a variety of natural products and biologically active compounds.¹ The strained structure, interesting bonding characteristics, and value as an internal mechanistic probe of the cyclopropane subunit have attracted the attention of the physical organic community.² As a consequence, considerable efforts have been made to develop new and effective approaches toward cyclopropane derivatives.³ Classical approaches to cyclopropane synthesis are the Simmons–Smith cyclopropanation.⁴ Transition-metal-catalyzed cyclopropanation of alkenes with diazo compounds represents a direct protocol for their preparation.⁵ Furthermore, the new types of cyclopropanation reactions based on nucleophilic addition-ring closure sequence were well documented (Scheme 1a and b).⁶ Nitrile-substituted cyclopropanes are of great interest as they are versatile templates for the rapid formation of biologically active and synthetically useful functionalized cyclopropane derivatives.⁷ Recently, nitrile-substituted cyclopropanes were synthesized *via* transition-metal-catalyzed olefin functionalization with diazoacetoneitriles.⁸ Despite the significant advancement, the development of complementary strategy toward functionalized cyclopropanes by using readily available substrates and cheap agents with high efficiency would be highly desirable.

α -Bromoennitrile is a class of readily available intermediate in organic synthesis.⁹ However, this intermediate is rarely used in organic synthesis compared to its analog α -bromoal.¹⁰

Recently, our group has reported a series of functionalization of 2-arylacetonitriles and their derivatives.¹¹ We hypothesized five-membered nitrogen containing heterocycles could be formed from 2-pyridylacetonitrile and α -bromoennitriles *via* [3 + 2] annulation. However, dinitrile-substituted cyclopropanes were afforded through a novel Michael-initiated ring closure procedure (Scheme 1c). Herein, we present a base-promoted synthesis of dinitrile-substituted cyclopropanes from 2-arylacetonitriles and α -bromoennitriles under mild conditions *via* Michael-initiated ring closure (Scheme 1d).

Initially, (*Z*)-2-bromo-3-phenylacrylonitrile **1a** and 2-pyridylacetonitrile **2a** were selected as the model substrates for the condition optimization. As illustrated in Table 1, a variety of commonly used organic and inorganic bases were screened. Among the tested organic bases, only DBU was found to afford the desired product in 38% yield (Table 1, entries 1–4). Then

^a Reaction conditions: **1a** (0.2 mmol), **2a** (0.2 mmol) and base (1.5 equiv.) in solvent (1.0 mL) for 12 h. ^b Yields of isolated *cis*-**3a** and *trans*-**3a** are given. *Cis* refers the two nitriles positioned on the same face of the cyclopropane; *trans* refers the two nitriles positioned on the opposite face of the cyclopropane.

various inorganic bases were examined. All of the inorganic bases had some effect on the reaction. We were pleased to find Cs₂CO₃ was the most suitable base and furnished the corresponding product in 95% yield (Table 1, entries 5–9). The control experiment revealed that the base was indispensable for the cyclization reaction, no product was produced without the addition of the base (Table 1, entry 10). Having this promising result, we subsequently evaluated the effects of several solvents. Solvent screening indicated that besides MeCN, DMF also promoted this reaction, whereas the use of DMSO, H₂O, DCE, THF and dioxane resulted in significantly lower yields (Table 1, entries 11–16). Finally, the reaction temperatures were investigated, and decreasing or increasing the temperatures led to diminishing yields (Table 1, entries 17–18). The *cis/trans* isomers ratio of the product was the same for 0° and room temperature. Therefore, base, solvent and reaction temperature are all essential for this transformation.

Having the developed optimal conditions for the Michael-initiated ring closure reaction, the substrate scope was investigated. As illustrated in Scheme 2, a wide range of 2-arylacetonitriles were tolerated with (*Z*)-2-bromo-3-phenylacrylonitrile **1a** to render dinitrile-substituted cyclopropanes in moderate to excellent yields (**3a–3u**). Except for 2-pyridylacetonitrile, 3-pyridyl and 4-pyridyl derivatives also reacted smoothly to generate the products in good yields (**3a–3c**). The annulation with 2-pyridylacetonitriles bearing electron-donating groups and

Scheme 2 Substrate scope of 2-arylacetonitriles^a. ^aReaction conditions: **1a** (0.2 mmol), **2** (0.2 mmol), Cs₂CO₃ (1.5 equiv.) and CH₃CN (1.0 mL) at room temperature for 12 h; isolated yields are given unless otherwise noted. *Cis* refers the two nitriles positioned on the same face of the cyclopropane; *trans* refers the two nitriles positioned on the opposite face of the cyclopropane. ^b2 mmol scale.

withdrawing groups in the pyridine ring worked well to deliver the products in satisfactory yields (**3d–3h**). Thienyl derivatives were reactive to afford the corresponding products, but exhibited lower reactivity compared with pyridyl (**3i–3j**). In addition to heteroaryl-substituted substrates, various 2-arylacetonitriles were further tested. The reaction conditions were compatible with an array of substituents, such as alkyl, methoxy, phenyl, chloro, bromo, trifluoromethyl, fluoro, and cyano groups (**3k–3u**). In particular, the aryl bromide could be further functionalized in metal-catalyzed cross-coupling reactions and hold the enormous potential application in pharmaceutical and materials science (**3p–3q**). To our delight, nitrile-containing substrate could provide the product **3u** in 86% yield. Significantly, the annulation reaction could be carried out on large-scale synthesis and formed the product **3a** in 87%

yield. The structure of **cis-3a** was verified by X-ray crystal analysis (CCDC: 2141258†).

Continuing to examine the generality and scope of the annulation reaction, we explored various α -bromoennitriles under the standard conditions (Scheme 3). α -Bromoennitriles bearing electron-rich or electron-deficient groups on the benzene ring reacted successfully with 2-pyridylacetonitrile to achieve the desired products in good yields (**4a–4h**). The substrates bearing a methyl at the *ortho*- and *meta*-positions of the benzene ring were suitable substrates for the transformation, thus indicating the steric hindrance is negligible (**4a–4b**). The bulky *tert*-butyl group was accommodated in this transformation (**4c** and **4j**). The disubstituted α -bromoennitrile proved to be good substrate under the same reaction conditions (**4d**). The reaction of the fused ring system also yielded the products in satisfactory yields (**4f**). Finally, phenylacetonitriles also worked well with α -bromoennitriles to obtain the corresponding product in good yields (**4i–4m**). The structure of **trans-**

Scheme 4 Synthetic application.

4b was further confirmed by X-ray crystal diffraction measurements (CCDC: 2142244†). It implied that this Michael-initiated ring closure reaction can be effective for the construction of dinitrile-substituted cyclopropane library.

To illustrate the applicability of this reaction, further transformation of product **cis-3a** was carried out as depicted in Scheme 4. 2,4-Dioxo-3-azabicyclo[3.1.0]hexane scaffold is known to be an important pharmacology agent and synthons for synthesis of functionally substituted cyclopropanes and various spirocompounds.¹² The target compound **5a** can be readily accessible in excellent yield *via* a simple hydrolysis reaction. It is worth noting that similar result was obtained for **trans-3a**.

A tentative mechanism for cyclopropane formation was proposed and outlined in Scheme 5 on the basis of aforementioned results as well as our experimental observations. Initially, carbanion intermediate **B** was produced *via* the sequential extraction of hydrogen proton and Michael-type addition process. Then the intermediate **B** was converted into intermediate **C** through 1,3-hydride transfer. Finally, the dinitrile-substituted cyclopropane **3a** was formed through intramolecular nucleophilic substitution. The diastereomer **3a** is the favored product due to steric effects, in which the two aryl groups are located on the opposite face of the plane of the cyclopropane moiety.

In summary, we have explored a convenient and highly efficient annulation reaction of 2-arylacetonitriles and α -bromoennitriles. A wide range of dinitrile-substituted cyclopropanes were obtained in moderate to excellent yields through a novel Michael-initiated ring closure procedure. The advantages of this transformation include readily accessible substrates, transition-metal-free conditions, good functional group tolerance, simple operation, *etc.* In addition, nitrile-
