MoO₂ nanosheets anchored with Co nanoparticles as a bifunctional electrocatalytic platform for overall water splitting†

Lu Xia,^a Yanjun Li,^a Hao Song,^{bc} Xingxing Li,^b Wenjie Gong,^a Xinyu Jiang,^a Mehran Javanbakht,^{id d} Xuming Zhang,^{id b} Biao Gao^{id *b} and Paul K. Chu^{id *c}

Electrochemical water splitting is one of the potential commercial techniques to produce clean hydrogen energy because of the high efficiency and environmental friendliness. However, development of low-cost bifunctional electrocatalysts that can replace Pt-based catalysts for the hydrogen evolution reaction (HER) and oxygen evolution reaction (OER) is challenging. Herein, Co nanoparticles (NPs) are anchored on MoO₂ nanosheets (Co/MoO₂) by thermal reduction of the CoMoO₄ nanosheet array in Ar/H₂. The uniformly distributed Co NPs improve the electron transfer capability and modulate the surface states of the MoO₂ nanosheets to enhance hydrogen desorption and HER kinetics. Moreover, the Co/MoO₂ composite is beneficial to the interfacial structure and the MoO₂ nanosheets prevent aggregation of Co NPs to improve the intrinsic OER characteristics in the alkaline electrolyte. As a result, the Co/MoO₂ electrocatalyst shows low HER and OER overpotentials of 178 and 318 mV at a current density of 10 mA cm⁻² in 1 M KOH. The electrolytic cell consisting of the bifunctional Co/MoO₂ electrodes shows a small voltage of 1.72 V for a current density of 10 mA cm⁻² in overall water splitting.

1 Introduction

Hydrogen (H₂) energy is one of the candidates to replace fossil fuels because of its environmental friendliness, small weight, and high energy density. Electrocatalytic water splitting is one of the preferred means to produce H₂ and O₂.^{1–3} Water splitting includes the hydrogen evolution reaction (HER) and oxygen evolution reaction (OER) that require proper catalysts to boost efficiency. Some noble metals such as Pt and Pd possess high electrocatalytic activity and low overpotentials in HER and noble metal oxide catalysts such as RuO₂ and IrO₂ are common catalysts for OER. However, the high cost and natural scarcity of these noble materials hamper large-scale commercial application.^{4–6} HER can take place in both acid and base media but OER is undesirable in acidic electrolytes. Hence, preparation of efficient bifunctional noble-metal-free electrocatalysis

for both HER and OER in alkaline media is challenging albeit of prime importance.

Owing to the high abundance and low cost, rutile molybdenum dioxide (MoO₂) is garnered interest in water splitting⁷ and nanostructures such as nanoparticles,⁸ nanobelts,⁹ nanosheets,¹⁰ nanoflowers,¹¹ nanowires¹² and hierarchical nanoarrays¹³ have been developed to improve H₂ evolution by increasing the surface area and increasing the reaction sites. Chen *et al.* have demonstrated that the Mo atom in MoO₂ is a high d-band center because of expansion of the Mo lattice upon incorporation of oxygen, resulting in unfavorable H₂ kinetics and poor H₂ evolution activity on MoO₂.¹⁴ Introducing transition metals to fill the empty d orbitals of Mo can weaken the Mo–H binding energy and improve the hydrogen evolution efficiency.^{15–18} Zhao *et al.* have constructed a CoP and MoO₂ heterostructure to coordinate interface electrons and accelerate dissociation of water and adsorption of hydrogen.¹⁹ Recent research activities have focused on improving the HER performance of MoO₂ catalysts but the OER characteristics have not been studied extensively.

Herein, MoO₂ nanosheets are anchored with Co nanoparticles (Co/MoO₂) to serve as bifunctional electrocatalysts for both HER and OER by reducing CoMoO₄ grafted on a carbon cloth in the Ar/H₂ atmosphere. In this process, CoMoO₄ is separated *in situ* to form the Co/MoO₂ heterojunction with abundant Co and MoO₂ interface consequently improving the HER and OER properties simultaneously, as demonstrated by low overpotentials of 178 mV and 318 mV to achieve a current

† Electronic supplementary information (ESI) available. See DOI: <https://doi.org/10.1039/d2ra06117a>

density of 10 mA cm^{-2} together with small Tafel slopes of $102.6 \text{ mV dec}^{-1}$ and 93.9 mV dec^{-1} in HER and OER in 1 M KOH, respectively. The electrolytic cell assembled with the bifunctional Co/MoO₂ electrocatalyst shows a low overall water splitting voltage of 1.72 V for a current density of 10 mA cm^{-2} . The results reveal a promising non-noble catalytic platform for low-cost and high-efficiency H₂ and O₂ production.

2 Experimental

2.1 Preparation of Co/MoO₂ nanoarrays, Co, and MoO₂

The carbon cloth (CC) pretreated with ethanol and acetone was soaked overnight in a nitric acid solution to enrich the surface oxygen-containing functional groups. After rinsing with ultrapure water, the CC was dried in a 60 °C oven. 0.1765 g of (NH₄)₆Mo₇O₂₄, 0.249 g of Co(CH₃COO)₂, 0.12 g of (NH₂)₂CO, and 0.185 g of NH₄F were dissolved in 30 mL of ultrapure water ultrasonically for 30 min, transferred to a 50 mL Teflon-lined stainless autoclave containing the CC, and heated to 150 °C for 6 h. After cooling to room temperature, the CC was taken out, rinsed three times with ultrapure water, and dried in a vacuum freeze-dryer for 12 h. Afterwards, the sample was pyrolyzed at 400 °C for 2 h at a heating rate of 5 °C min^{-1} in argon (Ar) and then Ar/H₂ (volume ratio: 90 : 10) at 550 °C for 2 h at a ramping rate of 5 °C min^{-1} to form the Co/MoO₂ nanoarrays.

Synthesis of Co proceeded in two steps. The CC was electrodeposited in a 0.1 M cobalt nitrate solution to produce Co(OH)₂ (ref. 20) and then annealed in Ar/H₂ (volume ratio: 90 : 10) at 550 °C for 2 h using a heating rate of 5 °C min^{-1} . The pretreated CC was hydrothermally treated to produce MoS₂ and subsequently reacted with air to form MoO₃.²¹ Finally, the MoO₃ sample was collected under Ar/H₂ (90 : 10) at a ramping rate of 5 °C min^{-1} to 650 °C for 2 h to form MoO₂ (Fig. S1†).

Pt/C and RuO₂ were fabricated by immersing the $1 \times 1 \text{ cm}^2$ CC in a uniform Pt/C (or RuO₂) solution and drying in air. The solution (1 mL) contained isopropanol and ultrapure water (volume ratio of 9 : 1), 1 mg of 20% Pt/C (or RuO₂), and 20 μL of 5% Nafion were sonicated to obtain a homogeneous solution.

2.2 Materials characterization

Field-emission scanning electron microscopy (FE-SEM, Apreo S HiVac) and transmission electron microscopy (TEM, JEM-F200) were performed to examine the microstructure of the materials. X-ray photoelectron spectroscopy (XPS, Axis Supra+) was carried out to determine the chemical states and X-ray diffraction (XRD, Bruker D8A A25) was conducted to investigate the structure.

2.3 Electrochemical evaluation

The electrochemical characteristics were determined on the biological VSP300-type electrochemical workstation with the three-electrode setup (Biologic Science Instruments, France) and N₂-saturated 1 M KOH as the electrolyte. The Co/MoO₂ electrode with a mass loading of 1 mg cm^{-2} was the working electrode, carbon rod was the counter electrode, and saturated calomel electrode (SCE) was the reference electrode. The

potentials were standardized as follows based on the reversible hydrogen electrode (RHE): $E(\text{RHE}) = E(\text{SCE}) + 0.059 \times \text{pH}$ with automatic 85% iR-compensation. Linear sweep voltammetry (LSV) was conducted at a scanning rate of 5 mV s^{-1} to obtain the polarization curves to assess the HER performance from -1.0675 to -1.5 V vs. RHE . Similarly, the polarization curves for OER were acquired from 0.8 to 1.8 V vs. RHE. The electrochemically active surface area (ECSA) was determined by cyclic voltammetry (CV) at scanning rates ranging from $50\text{--}90 \text{ mV s}^{-1}$ and -0.6 to -0.8 V vs. SCE . Electrochemical impedance spectroscopy (EIS) was carried out from 100 kHz to 0.1 Hz with 0.5 V vs. SCE . The water splitting electrolyser comprises the bifunctional Co/MoO₂ electrodes and 1 M KOH electrolyte.

3 Results and discussion

As shown in Fig. 1, CoMoO₄ nanosheets synthesized on CC hydrothermally are annealed in a reductive Ar/H₂ ambient. The CoMoO₄ nanosheets cover the CC uniformly and the size of the nanosheets are about 10 μm as shown in Fig. 2a. CoMoO₄ is then annealed in Ar/H₂ at 550 °C for 2 h and CoMoO₄ decomposes into Co and MoO₂ composites while maintaining the nanosheet structure of CoMoO₄. The nanoparticles are evenly dispersed on the surface of nanosheets (Fig. 2b and c). Co/MoO₂ is examined by TEM and Fig. 2d and e disclose that the nanoparticles on the nanosheets are about 20–30 nm in size. The high-resolution TEM (HR-TEM) image (Fig. 2f) reveals distinct lattice fringes with an interplanar distances of 0.21 nm and 0.245 nm corresponding to the (111) and (−202) planes of the Co and MoO₂, respectively.^{22,23} The elemental maps of Co/MoO₂ in Fig. 2g corroborate uniform distributions of Co nanoparticles on the MoO₂ nanosheets.

To determine the phase constituents, CoMoO₄ and Co/MoO₂ are analyzed by XRD. Fig. 3a exhibits diffraction peaks at 25.5° , 33.7° , 59.9° , 61.9° , and 63.1° corresponding to CoMoO₄ (JCPDS No. 21-0868) (ref. 21) and new phases of MoO₂ (JCPDS NO. 78-1070) (ref. 22) and metallic cobalt (JCPDS No. 15-0806) (ref. 23) are formed after reduction at 550 °C for 2 h in Ar/H₂. The results demonstrate that the CoMoO₄ precursor is reduced in Ar/H₂ to generate Co and MoO₂.

The change in the chemical states after phase separation is monitored by X-ray photoelectron spectroscopy (XPS). As shown in Fig. 3b, Co/MoO₂ exhibits peaks of Co, Mo, O, and C. The fine spectrum of Co 2p of CoMoO₄ in Fig. 3c can be fitted with peaks at 781.3 (Co²⁺ 2p_{3/2}), 797.2 (Co²⁺ 2p_{1/2}), 785.1, and 802.8 eV corresponding to the cobalt oxide Co^(II) and satellite peaks,²⁴ respectively. The metallic Co peaks of Co/MoO₂ at 778.5 eV (Co⁰ 2p_{3/2}) and 793.5 eV (Co⁰ 2p_{1/2})²⁵ confirm that cobalt is formed in

Fig. 1 Schematic illustration of the fabrication of Co/MoO₂.

Fig. 2 FE-SEM images of (a) CoMoO₄ and (b and c) Co/MoO₂, (d–f) TEM image of Co/MoO₂, and (g) elemental maps of Co/MoO₂.

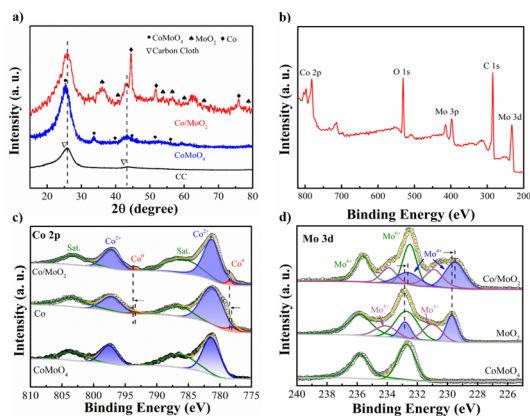

Fig. 3 (a) XRD patterns of CC, CoMoO₄ and Co/MoO₂, (b) XPS spectrum of Co/MoO₂, and high-resolution XPS spectra of (c) Co 2p and (d) Mo 3d of CoMoO₄, Co/MoO₂, MoO₂ and Co.

the phase separation process. It can be seen that the Co 2p spectra of Co/MoO₂ varied to a higher binding energy than Co, manifesting the electrons depletion region on the sample of Co. Fig. 3d shows two peaks at 232.6 eV and 235.8 eV in the Mo 3d XPS spectrum associated with Mo 3d_{5/2} and Mo 3d_{3/2} of the Mo⁶⁺ state of CoMoO₄.²⁶ With regard to the reduced sample, the peaks at 229.5, 232.6, 230.8, 233.8, 232.5, and 235.5 eV are ascribed to the intermediate states of Mo⁴⁺, Mo⁵⁺ and Mo⁶⁺, further confirming the formation of MoO₂.^{27–31} As shown in the graph, the Mo 3d spectra of Co/MoO₂ transferred to a lower binding energy as contrasted with the sample of MoO₂, which demonstrate the electrons accumulation on the MoO₂. Thus, the electrons transfer from Co to MoO₂.

The electrocatalytic OER and HER characteristics are determined by LSV at a scan rate of 5 mV s^{−1} using a three-electrode configuration in N₂-saturated 1 M KOH. A low overpotential (η) and small Tafel slope reflect high electrocatalytic activity in OER and HER at the desired large current density. For comparison Co, MoO₂, RuO₂ and Pt/C catalysts are also studied. Fig. 4a and c

Fig. 4 (a) OER polarization curves of CoMoO₄, Co/MoO₂, MoO₂, Co, and RuO₂, (b) HER polarization curves of CoMoO₄, Co/MoO₂, MoO₂, Co, and 20% Pt/C, (c) Tafel plots for OER, (d) Tafel plots for HER, (e) Co/MoO₂ galvanostatic results for OER, and (f) Co/MoO₂ galvanostatic results for HER.

present the OER polarization and corresponding Tafel plots of the samples. The OER overpotential (η_{10}) of Co/MoO₂ is 318 mV, which is better than those of CoMoO₄ (355 mV), RuO₂ (345 mV), Co (343 mV) and MoO₂ (470 mV). It is due to better electron transfer from Co to MoO₂ at the Co/MoO₂ interface consequently enriching the positive charges on the Co surface and simultaneously reducing the adsorption capacity of Co particles to oxygen species at the interface, resulting in enhanced oxygen evolution activity.³² Therefore, the Co/MoO₂ composite is beneficial to the interfacial structure to enhance the intrinsic activity. Co and MoO₂ promote oxygen evolution in alkaline solutions. Moreover, η_{10} of Co/MoO₂ is better than those of previously reported catalysts such as MoO₂/NF (350 mV),³³ MoO₂+OH[−] (435 mV),³⁴ MoO₂-Co (378 mV),³⁵ MoO₂-Co₂Mo₃-O₈@C (320 mV),³⁶ Co₂N_{0.67}-BHPC (340 mV),³⁷ Co/ β -MoO₂-C@N-CNTs (356 mV)³⁸ (Table S1†). The corresponding Tafel slope of Co/MoO₂ is 93.9 mV dec^{−1}, which is smaller than those of CoMoO₄ (102 mV dec^{−1}), Co (98.6 mV dec^{−1}), and MoO₂ (99.8 mV dec^{−1}). Hence, Co/MoO₂ has a smaller η_{10} and Tafel slope on account of the synergistic effects rendered by the individual heterostructures such as rapid desorption of gas and maintenance of active sites during gas generation.¹³ Electron transfer between Co and MoO₂ enhances the electron donating ability and the bonding force between the transition metal Co and OH[−] increases to improve the OER performance.²⁹ In addition, metallic cobalt enhances the oxygen evolution kinetics of Co/MoO₂ by promoting the conductivity and accelerating transfer of electrons. Therefore, Co/MoO₂ prepared by phase separation boosts the oxygen evolution capability.

The electrocatalytic HER properties are determined by LSV is shown in Fig. 4b and d. Co/MoO₂ shows a smaller η_{10} of 178 mV compared to CoMoO₄ (272 mV), Co (192 mV), and MoO₂ (380 mV). For comparison, the Pt/C catalyst has a η_{10} of 59 mV in 1 M KOH. The HER properties of Co/MoO₂ are better than of recently reported catalysts including MoO₂ (200 mV),³⁹ MoO₂/NF (187 mV),³³ Co@ β -Mo₂C-NC-0.115 (188 mV),⁴⁰ MoO₂-Co (422 mV),³⁵ Co-CoO/BC (210 mV),⁴¹ Mo₂C/MoO₂ (204 mV)⁴² (Table S2†). The HER reaction involves two stages.⁴³ The first steep is the Volmer reaction with a Tafel slope of about 118 mV dec⁻¹ and the second one is the Heyrovsky reaction with a Tafel slope of approximately 39 mV dec⁻¹ or Tafel reaction with a Tafel slope of 29 mV dec⁻¹. The HER Tafel slope of Co/MoO₂ is 102.6 mV dec⁻¹ indicative of the Volmer-Heyrovsky mechanism. The hydrogen evolution reaction requires a large number of protons which in an alkaline solution originate from dissociation of water. Therefore, the hydrogen evolution rate of Co/MoO₂ in the alkaline solution is governed by the Volmer reaction. The Tafel slope of Co/MoO₂ is smaller than those of CoMoO₄ (115.3 mV dec⁻¹), Co (132.6 mV dec⁻¹), and MoO₂ (121.1 mV dec⁻¹). Metallic cobalt provides the H* adsorption sites to promote water dissociation and improving the Co/MoO₂ HER properties.⁴⁴ Furthermore, Mo-H has a strong adsorption energy which inhibits desorption. The electronic structure of Mo is regulated by the transition metal Co, which diminishes the Mo-H binding energy and makes it easier to desorb. Consequently, hydrogen evolution from Co/MoO₂ is further improved.¹³ When Co/MoO₂ transfers electrons from Co to MoO₂, the Co surface is enriched with positive charges and the Co particles near the interface decreases the ability to adsorb hydrogen to enhance hydrogen evolution.⁴⁵ Therefore, the Co/MoO₂ heterojunction improves the intrinsic activity of Co and MoO₂ synergistically in the alkaline solution. Galvanostatic tests are performed on the Co/MoO₂ catalyst for both OER and HER as shown in Fig. 4e and f further revealing the stability in the electrochemical reaction.

The electrochemical active surface area (ECSA) is another critical parameter for the catalytic activity and characterized by the electrochemical double layer capacitance (C_{dl}). Cyclic voltammetry (CV) is performed at different scanning rates in the non-Faraday current interval (Fig. S2†). The electric double layer capacitance is related to the number of active sites in the electrochemical reaction⁴⁶ and CV is utilized to determine the number of active sites. As shown in Fig. 5a, the C_{dl} value of Co/MoO₂ (23.2 mF cm⁻²) is bigger than those of MoO₂ (3.4 mF cm⁻²) and Co (5.8 mF cm⁻²), implying that the Co/MoO₂ catalyst has more active sites. Electrochemical impedance spectroscopy (EIS) is employed to study the interfacial dynamics and as shown in the equivalent series model composed of the solution resistance R_s (intersection between the high frequency region and X-axis), CPE (constant phase angle element), and parallel R_{ct} , the faster charge transfer and transmission, the smaller is the diameter of the semi-circular R_{ct} . Fig. 5b shows smaller R_{ct} than others (Fig. S3†) because that *in situ* formation of Co/MoO₂ reduces the interface resistance and raises the charge conduction rate thus exploiting the synergetic effects rendered by Co and MoO₂. The calculated differential charge

Fig. 5 (a) Current densities ($\Delta j = j_{\text{anode}} - j_{\text{cathode}}$, at 0.36 V) as a function of scanning rates of Co/MoO₂, MoO₂ and Co with the corresponding slope being twice that of C_{dl} , (b) Nyquist plots collected at 500 mV vs. SCE of Co/MoO₂, MoO₂ and Co, (c) differential charge densities of Co/MoO₂, and (d) density of states of Co/MoO₂, MoO₂ and Co.

density in Fig. 5c illustrates that the charge density redistributes at the interface showing an electron accumulation region (yellow region) on the MoO₂ side and electron loss region (blue region) on the Co side, indicating electron transfer from Co to MoO₂. The density of states (DOS) in Fig. 5d reveals that the state of Co/MoO₂ is located at the Fermi level higher than MoO₂ and Co, thereby explaining why Co/MoO₂ improves the electron activity as consistent with the Fig. 5b.

Co/MoO₂ catalysts are prepared at different temperature and the HER and OER characteristics are evaluated by LSV to assess the influence of the catalyst configuration and composition on the electrochemical properties (Fig. S4†). Owing to the proper structure, Co/MoO₂ prepared at 550 °C delivers better electrocatalytic performance than other samples. As shown in Fig. S5 and S6,† when the temperature is 450 °C, the nanosheets are still CoMoO₄ and no particles are deposited on the nanosheets. However, at 650 °C, the morphology changes into a porous network because of the formation of the new phase of Co₃Mo (JCPDS NO. 29-0488).¹³

The Co/MoO₂ catalysts are assembled as the anode and cathode to conduct overall water splitting in 1 M KOH. The cell

Fig. 6 (a) Water splitting LSV curves of Co/MoO₂ as both the cathode and anode and (b) Co/MoO₂ water splitting electrolyzer galvanostatic test for 12 h at 10 mA cm⁻².

voltage is 1.72 V at a current density of 10 mA cm⁻², which is competitive to the other non-noble metal bifunctional catalysts reported in the literature, including Co@β-Mo₂C-NC-0.115 (1.72 V),⁴⁰ Co₂P/Mo₂C/Mo₃Co₃C@C (1.74 V),⁴⁷ Co-CoO/BC (1.77 V),⁴¹ P-MoO₂ (1.83 V),⁴⁸ NiO/NiFe₂O₄ (1.82 V)⁴⁹ (Table S3†). The overall water splitting potential of the Co/MoO₂-based electrolyzer rises slightly after continuous operation for 12 h in the alkaline solution (Fig. 6).

4 Conclusions

A Co/MoO₂ catalyst is fabricated by a one-step phase separation process of CoMoO₄ in the Ar/H₂ atmosphere. The *in situ* generated metallic Co nanoparticles on the MoO₂ nanosheets improve the HER characteristics of MoO₂, whereas the MoO₂ nanosheets impede agglomeration of nanosized Co in OER. The Co/MoO₂ composite shows superior HER and OER properties compared to single-phase catalysts of Co and MoO₂. In the alkaline solution, the η_{10} values of Co/MoO₂ for HER and OER are 178 and 318 mV, respectively. The electrolytic cell assembled with the bifunctional Co/MoO₂ electrocatalyst shows a low voltage of 1.72 V for a current density of 10 mA cm⁻² in overall water splitting. The *in situ* separation strategy to form the transition metal and oxide heterojunction has large potential in designing non-noble metal catalysts for electrocatalytic water splitting and other applications.
