# Ultrafast and selective labeling of endogenous proteins using affinity-based benzotriazole chemistry†

Xiaoyi Xin,<sup>‡a</sup> Yu Zhang,<sup>‡a</sup> Massimiliano Gaetani,<sup>cd</sup> Susanna L. Lundström,<sup>cd</sup> Roman A. Zubarev,<sup>cd</sup> Yuan Zhou,<sup>b</sup> Dale P. Corkery<sup>‡a</sup> and Yao-Wen Wu<sup>id</sup>\*<sup>a</sup>

Chemical modification of proteins is enormously useful for characterizing protein function in complex biological systems and for drug development. Selective labeling of native or endogenous proteins is challenging owing to the existence of distinct functional groups in proteins and in living systems. Chemistry for rapid and selective labeling of proteins remains in high demand. Here we have developed novel affinity labeling probes using benzotriazole (BTA) chemistry. We showed that affinity-based BTA probes selectively and covalently label a lysine residue in the vicinity of the ligand binding site of a target protein with a reaction half-time of 28 s. The reaction rate constant is comparable to the fastest biorthogonal chemistry. This approach was used to selectively label different cytosolic and membrane proteins *in vitro* and in live cells. BTA chemistry could be widely useful for labeling of native/endogenous proteins, target identification and development of covalent inhibitors.

## Introduction

Selective chemical labeling of proteins is highly valuable for studying and controlling protein structures, dynamics and functions *in vitro* and in living systems,<sup>1–9</sup> for development of new materials<sup>10</sup> and for drug development.<sup>11–13</sup> As proteins carry many copies of various functional groups, it is challenging to selectively label a protein at a defined site.<sup>14</sup> Moreover, the labeling conditions have to be mild in aqueous solution and reactions should be orthogonal to other functionalities in living systems when a protein is to be labeled *in vivo*. Numerous chemical tagging approaches in combination with bio-orthogonal chemistry enable incorporation of chemical probes into proteins in cells and organisms.<sup>3,15–18</sup> Although these approaches are versatile and robust, most of these approaches rely on exogenous expression of protein of interest (POI) with genetic tags or non-canonical amino acids.<sup>2,6,8,19–22</sup> The advance in selective labeling of endogenous proteins facilitates affinity-based protein profiling,<sup>23</sup> proteomic analysis of cellular

organelles and protein complexes,<sup>24</sup> target identification,<sup>25</sup> and diagnosis.<sup>26</sup>

Affinity labeling of proteins based on proximity-driven chemistry has been a powerful approach for selective labeling of native or endogenous proteins,<sup>27</sup> and for the development of covalent inhibitors.<sup>11</sup> Following the protein–ligand interaction, the electrophilic group of the probe is placed in proximity of the POI, thereby facilitating nucleophilic attack by residues in the vicinity of the ligand-binding site, leading to covalent binding. Depending on the purpose of application, affinity labeling approaches can afford the covalent binding of ligands that eventually disrupts protein function or locks the protein at a defined state. Alternatively, these approaches can label native or endogenous proteins without functional disruption owing to the concomitant release of ligands upon labeling. In the latter, ligand-directed probes that consist of a ligand for the POI, an electrophilic leaving group and a tag have been used for covalent attachment of a desired tag to the POI. The operation is very facile without genetic manipulation.

A range of reactive groups have been developed and used in affinity labeling of proteins, including classical electrophiles such as  $\alpha$ -halocarbonyls, epoxides, acrylamides, vinyl sulfonates, *etc.* (Fig. 1a), which have been used for covalent binding of ligands/inhibitors.<sup>28–32</sup> The emerging ligand-directed chemistry has been used to label endogenous proteins in living systems, including tosyl (LDT),<sup>33–35</sup> alkyloxyacyl imidazole (LDAI),<sup>36–38</sup> *O*-nitrobenzoxadiazole (*O*-NBD),<sup>39</sup> dibromophenylbenzoate (LDBB),<sup>40</sup> difluorophenylbenzoate,<sup>41</sup> *N*-sulfonyl pyridone,<sup>42</sup> and *N*-acyl-*N*-alkyl sulfonamide (LDNASA) chemistry (Fig. 1a).<sup>43</sup> These reactive groups are relatively less reactive

towards nucleophiles under certain conditions, while the reaction is accelerated by proximity effect to achieve selectivity. However, most of the affinity-labeling reagents suffer from sluggish reaction rates, which require hours to a day to yield sufficiently labeled proteins. Recently, the LDNASA strategy achieves the most rapid reaction rate with a second-order rate constant in the range of  $10^4 \text{ M}^{-1} \text{ s}^{-1}$ .<sup>43</sup> Therefore, new reactive groups for affinity labeling with fast reaction rates and good selectivity remain in high demand. Herein, we report a benzotriazole (BTA) chemistry that can be incorporated into affinity labeling probes for rapid and selective labeling of native or endogenous proteins *in vitro* and in cells.

## Results and discussion

Benzotriazole contains two electron-deficient  $\text{sp}^2$  nitrogen atoms ( $\text{N}^2$  and  $\text{N}^3$ ) and the  $\text{p}K_{\text{a}}$  of the  $\text{N}^1\text{-H}$  is *ca.* 8. It has been

used as an efficient synthetic auxiliary group for the *N*-substitution of various compounds in organic synthesis, because the benzotriazolone anion is a good leaving group and *N*-substituted derivatives are easy to prepare.<sup>44,45</sup> Moreover, ligands or chemical handles could be placed on the phenyl ring for a design of affinity labeling probes (Fig. 1b).

As proof of principle, we designed compound 1, in which a synthetic ligand for the FKBP12 protein (SLF)<sup>46</sup> is linked to a biotin tag *via* the benzotriazole moiety and linkers (Fig. 1c). The covalent conjugation of 1 with the recombinant FKBP12 protein was evaluated by denaturing SDS-PAGE and monitored by western blot of biotin. Reaction of  $5 \mu\text{M}$  FKBP12 with  $10 \mu\text{M}$  compound 1 proceeded rapidly in aqueous solution with a half-time of 113 s (Fig. 2a and b). According to the equation of observed rate constant ( $k_{\text{obs}}$ ), under the conditions used (the concentration of reagent is much higher than  $K_{\text{d}}$  of ligand

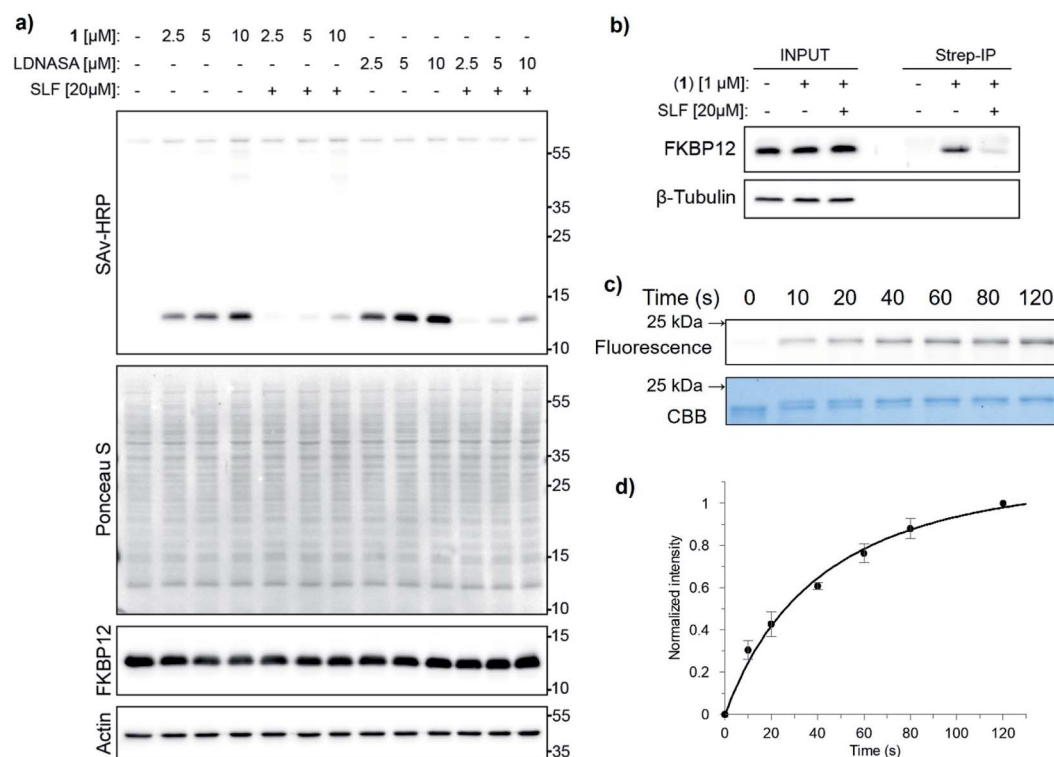

**Fig. 2** *In vitro* labeling of FKBP12 protein. (a) SDS-PAGE and western blotting analysis of labeling reaction of 5  $\mu\text{M}$  FKBP12 with 10  $\mu\text{M}$  **1**. (b) Kinetics of labeling reactions of 5  $\mu\text{M}$  FKBP12 using 10  $\mu\text{M}$  **1** (red) vs. LDNASA (blue). The solid line shows the fitting to a single-exponential equation for determining  $t_{1/2}$ . Error bars represent standard deviation of three independent experiments. (c) The crystal structure of the FKBP12-SLF complex (PDB ID: 1FKG). The labelling sites of **1** are marked as red (Lys52, the major labelling site) and blue (Lys35, the minor labelling site). SLF is shown in green sticks.

binding), the observed ultrafast reaction rate reflects the reactivity of the BTA chemistry driven by proximity effect ( $k_{\text{chem}}$ ) (ESI $\dagger$ ). Addition of parental ligand SLF led to abolishment of the conjugation, suggesting that the BTA reaction is selectively driven by a proximity effect mediated by ligand binding (Fig. 2a). In order to compare with the reaction rate of LDNASA chemistry, we prepared the same LDNASA probe that was reported to afford the highest rate constant in affinity-labeling reagents and measured the kinetics for labeling of the FKBP12 protein (Fig. S1 $\dagger$ ).<sup>43</sup> Under the same conditions, the observed half-time of the labeling reaction by LDNASA was

determined to be 151 s. Therefore, the affinity labeling of FKBP12 by BTA chemistry is *ca.* 1.3-fold faster than LDNASA chemistry.

The stability of the BTA probe **1** in DMSO and in aqueous buffer was measured by HPLC. The half-life of **1** was determined to be 3.7 h in neutral buffer at 37  $^{\circ}\text{C}$ . 63% of **1** remained intact after 48 h in DMSO at 37  $^{\circ}\text{C}$ , while no detectable degradation of **1** was observed in DMSO at  $-20$   $^{\circ}\text{C}$  for more than 10 months (Fig. S2 $\dagger$ ). Therefore, the BTA probe is stable enough for labeling reactions. Reaction of **1** with FKBP12 led to conjugation of one or two biotin groups to the protein (Fig. S3 $\dagger$ ). A peptide

The solid line shows the fitting to an equation for determining the rate constant of second-order reaction (ESI $\dagger$ ). Error bars represent standard deviation of three independent experiments.

mapping analysis was carried out to determine the labeling site(s) on FKBP12. After reaction with **1**, FKBP12 was digested with trypsin and subjected to LC-MS/MS analysis (ESI<sup>+</sup>). The results showed that Lys52 (*ca.* 11 Å away from SLF) is the major labeling site and Lys35 (*ca.* 17 Å away from SLF) is the minor labeling site (Fig. 2c and S4<sup>†</sup>). Both sites are in the vicinity of the SLF-binding site on FKBP12 (Fig. 2c). The results showed that the BTA probe undergoes nucleophilic attack by the ε-amino group of lysine side chains to attach a biotin group to the protein with concomitant release of the ligand.

To examine the feasibility of using BTA chemistry in biological contexts, we labeled FKBP12 with **1** in cell lysates. HeLa cell lysate (total protein concentration of 1.5 mg mL<sup>-1</sup>) was mixed with recombinant FKBP12 (2 μM) and **1** (up to 10 μM) at 37 °C. The labeling reaction was completely abolished by SLF (Fig. 3a). Non-specific labelling was not observed with up to 10 μM **1** at reaction times of up to 2 h (Fig. S5<sup>†</sup>). To demonstrate labeling of endogenous FKBP12 in live cells, we incubated HeLa cells with 1 μM **1** and subjected the labeled cell lysates to immunoprecipitation using streptavidin beads. We observed specific pull-down of endogenous FKBP12, which was abolished by SLF (Fig. 3b). These results suggest that BTA chemistry is biorthogonal and can be used for selective labeling of endogenous proteins in biological contexts.

Prompted by the results of **1**, we used BTA chemistry to label a new protein. Autophagy is an evolutionarily conserved intracellular degradation system through which cytoplasmic constituents are sequestered in double-membrane autophagosomes and delivered to lysosomes for clearance. Recently, we reported novel autophagy inhibitors, autogramins, and identified their cellular target GRAMD1A, a cholesterol-transfer protein localizing at the endoplasmic reticulum (ER) membrane contact sites. Autogramins compete with cholesterol binding to the StART domain of GRAMD1A, thereby inhibiting

its cholesterol transfer activity that is required for autophagosome biogenesis.<sup>47,48</sup> GRAMD1A also plays an important role in cholesterol homeostasis at ER-plasma membrane contact sites.<sup>49,50</sup> We prepared compound **2** containing autogramin-2, the BTA moiety and azide as a biorthogonal handle (Fig. 1d). Recombinant StART domain of GRAMD1A protein was reacted with **2**. Reaction of **2** with GRAMD1A led to conjugation of a single azide group to the protein (Fig. S6<sup>†</sup>). The labeling was detected by incorporation of the DBCO-TAMRA fluorescent dye into the protein *via* strain-promoted azide-alkyne cycloaddition as well as by the shift of mobility of the labeled protein in SDS-PAGE (Fig. 3c). Reaction of 5 μM GRAMD1A with 10 μM compound **2** proceeded rapidly in aqueous solution with a half-time of 28 s. The second-order reaction rate constant of BTA probe **2** was determined to be  $(2.7 \pm 0.4) \times 10^3 \text{ M}^{-1} \text{ s}^{-1}$  (Fig. 3d, ESI<sup>†</sup>). A peptide mapping analysis using LC-MS/MS showed that Lys158 (*ca.* 11.6 Å away from autogramin-2) is the major labeling site (Fig. S7<sup>†</sup>), suggesting that the BTA probe undergoes nucleophilic attack by the ε-amino group of lysine side chain in the vicinity of the ligand-binding site to attach an azide group to the protein with concomitant release of the ligand.

To demonstrate the application of BTA chemistry to labeling and imaging of endogenous proteins in live cells, we prepared compound **3** that consists of arylsulfonamide as a ligand for carbonic anhydrases (CAs), BTA and fluorescein as a fluorescent reporter. Carbonic anhydrases are a family of enzymes that catalyze the interconversion between carbon dioxide and carbonic acid. CA and its inhibitor arylsulfonamides have been serving as an important model for studies of protein-ligand interaction.<sup>51</sup> The cell-surface transmembrane CAs (CA9 and CA12) are overexpressed in many tumors and appear to be regulated by microenvironmental hypoxia. They contribute to the tumor microenvironmental acidity and tumor malignant phenotype, making them a valuable diagnostic and prognostic

**Fig. 4** Labeling of endogenous CA12 using **3**. (a) Representative confocal fluorescent images of MCF7 cells treated with **3** in the absence and the presence of EZA. Nuclei were counterstained with Hoechst 33342. Scale bars, 10 μm. (b) Quantification of fluorescein fluorescence intensity from (a). Data were shown as mean ± sd from three biologically independent experiments. Data points represent individual cells pooled from the three independent experiments (*n* > 100 cells). Significance was determined from biological replicates using a one-way ANOVA with Tukey's multiple comparisons tests. \*\**p* = 0.0014, \*\*\**p* = 0.0009. (c) Western blot analysis of MCF7 cells treated with **3** in the absence and the presence of EZA. (d) MCF7 cells labeled with **3** were subjected to immunoprecipitation using the anti-FITC antibody. CA12 and the fluorescein-labeled protein were visualized using antibodies against CA12 and FITC, respectively. Data are representative of three independent experiments.

biomarker for cancer.<sup>52–54</sup> CA12 is overexpressed in breast cancer cells and is transcriptionally regulated by estrogen receptor  $\alpha$  (ER $\alpha$ ).<sup>55</sup> To label the cell surface membrane protein, probe 3 was prepared with a fluorescein dye containing carboxylic acid to make it less cell-permeable. Confocal microscopy showed that probe 3 quickly labels the plasma membrane of the breast cancer cell line MCF-7. The labeling was abolished by the inhibitor of CAs, ethoxzolamide (EZA) (Fig. 4a and b). To confirm the specificity of the labeling, MCF-7 cells labeled with 3 were lysed and subjected to denaturing SDS-PAGE. Selective covalent labeling of CA12 was confirmed by western blot and immunoprecipitation (Fig. 4c and d). The observed multiple bands of CA12 correlate with its glycosylation in cells.<sup>56</sup> Immunoprecipitation using the anti-fluorescein isothiocyanate (FITC) antibody led to specific pull-down of CA12, which was abolished by EZA (Fig. 4d). These results demonstrated that BTA chemistry can be used to selectively label endogenous proteins in live cells.

In summary, we have developed BTA chemistry, which shows high selectivity, bioorthogonality and rapid reaction kinetics for labeling of endogenous proteins. The reaction rate of BTA chemistry was faster than LDNASA chemistry, and was comparable to the fastest biorthogonal reactions. The modular design of BTA probes makes it facile to label various cytosolic and membrane proteins with different tags. We envision that BTA chemistry could be an invaluable tool for labeling of native/endogenous proteins, target identification and development of covalent inhibitors.
