Surfactant encapsulating N-doped carbon dots with enhanced optical properties as a selective sensor for Cr(VI) detection

The schematic illustrates the synthesis of N-CDs-CTAC from N-CDs via post-modification with CTAC, followed by dynamic quenching with Cr(VI). The legend identifies N-CDs as green circles, N-CDs-CTAC as green circles with blue outlines, CTAC as red wavy lines, and Cr(VI) as yellow dots. The process involves irradiation at 405 nm and 535 nm. A graph shows PL intensity vs. wavelength for N-CDs, N-CDs-CTAC, and N-CDs-CTAC+Cr(VI), demonstrating quenching.

Fe–N hollow mesoporous carbon spheres with high oxidase-like activity for sensitive detection of alkaline phosphatase

The diagram illustrates the synthesis and catalytic application of Fe-N HMCS.
Synthesis: Formaldehyde, FeCl₃, TEOS, and 3-aminophenol are stirred to form Fe/SiO₂/APF. This intermediate is then heated at 700 °C for 5 h under N₂ atmosphere, followed by 10% HF treatment, to produce Fe-N HMCS.
Catalytic Cycle: AAP (Ascorbic Acid Phosphate) is converted to AA (Ascorbic Acid) by the enzyme ALP. AA then reduces ROS (Reactive Oxygen Species) to O₂ (Oxygen), regenerating AAP in the process.

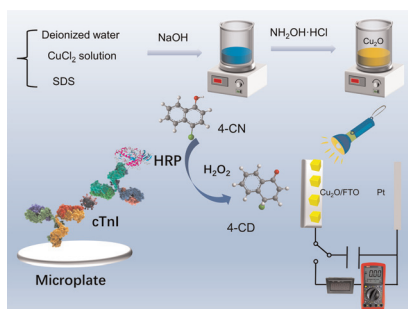

Charting and tracking the evolution of the SARS CoV-2 coronavirus variants of concern with protein mass spectrometry

Hollow structure molecularly imprinted ratiometric fluorescence sensor for the selective and sensitive detection of dopamine

The diagram illustrates the synthesis of ZIF-8/CdTe/MIPs. It begins with CdTe nanoparticles (red spheres) and Zn(NO₃)₂·6H₂O reacting under Himm conditions to form ZIF-8/CdTe. This intermediate is then reacted with CD₄, DA, and 4VPBA in the presence of AM, MBA, and AIBN to form ZIF-8/CdTe/CDs@MIPs with DA. Finally, the DA is removed via elution to yield ZIF-8/CdTe/CDs@MIPs.
