The  $(i\text{Pr})\text{CuOtBu}$  catalysed reduction of 11 aryl and alkyl isocyanates with pinacolborane gave only the boraformamides,  $\text{pinBN}(\text{R})\text{C}(\text{O})\text{H}$ , in most cases. Overreduction, which hampers almost all isocyanate hydroborations, was restricted to electron poor aryl isocyanates (4-NC-C<sub>6</sub>H<sub>4</sub>NCO, 4-F<sub>3</sub>C-C<sub>6</sub>H<sub>4</sub>NCO, 3-O<sub>2</sub>N-C<sub>6</sub>H<sub>4</sub>NCO). Computational analysis showed stability of  $[(i\text{Pr})\text{CuH}]_2$ , which was proposed to be the catalyst resting state, drives selectivity, suggesting an approach to prevent overreduction in future work. In the case of  $i\text{PrNCO}$ , formation of this species renders overreduction kinetically inaccessible. For 4-NC-C<sub>6</sub>H<sub>4</sub>NCO, however, the barrier height for the first step of over-reduction is much lower, even relative to  $[(i\text{Pr})\text{CuH}]_2$ , resulting in unselective reduction.

Catalytic reduction of isocyanates leveraging p-block hydrides has emerged as a generalisable route to *N*-methyl amines *via* the deoxygenation of intermediate formamide derivatives. This transformation has been reported to be catalysed by zirconium, magnesium,<sup>1–3</sup> platinum and boron-centred<sup>4</sup> catalysts; or *via* the uncatalysed action of boranes<sup>5</sup> and alanes<sup>6–8</sup> upon these substrates. Selective generation of the partially reduced formamide derivatives containing the  $-\text{N}(\text{R})\text{C}(\text{O})\text{H}$  fragment remains challenging, limited to the stoichiometric action of alane and zirconium derived systems upon these substrates<sup>9</sup> and restricted reports of hydrogenation<sup>10,11</sup> and hydrosilylation<sup>12</sup> under palladium catalysis. A recent report by Nembenna showed that a zinc catalyst can provide a highly chemoselective route to boraformamides through the reaction of isocyanates with pinacolborane *via* a zinc(II) hydride intermediate.<sup>13</sup> This was followed by a report of a similarly selective reduction catalysed by LiHB<sub>2</sub>Et<sub>3</sub> by Ding and co-workers.<sup>14</sup> This dearth of chemoselective transformations contrasts with another group

## Selective hydroboration of electron-rich isocyanates by an NHC-copper(I) alkoxide†

Laura E. English, <sup>ab</sup> Thomas M. Horsley Downie, <sup>a</sup> Catherine L. Lyall, <sup>a</sup> Mary F. Mahon, <sup>a</sup> Claire L. McMullin, <sup>a</sup> Samuel E. Neale, <sup>a</sup> Carla M. Saunders <sup>a</sup> and David J. Liptrot <sup>a</sup>

of heteroallenenes, the carbodiimides, where selective access to the formamidine derivatives, containing  $-\text{N}(\text{R})\text{C}(\text{NR})\text{H}$ , is facile.<sup>15</sup>

Following the initial report of  $[\text{CuH}(\text{PPh}_3)]_6$  in 1971,<sup>16</sup> and its subsequent exploration in reduction of carbonyl derivatives by Stryker and co-workers,<sup>17,18</sup> copper(I) hydrides have emerged as increasingly popular reducing agents.<sup>19</sup> Subsequent extension of the ancillary ligand on copper to encompass NHCs (N-heterocyclic carbenes)<sup>20</sup> has fuelled an explosion in the catalytic and stoichiometric implication of copper(I) hydrides in productive transformations. This growth is in no small part a consequence of the facile synthesis of  $[(\text{NHC})\text{CuH}]_n$  systems *via* the action of main group hydrides on copper-element bonds. For example, Sadighi and co-workers described the synthesis and characterisation of  $[(i\text{Pr})\text{CuH}]_2$  ( $i\text{Pr} = 1,3$ -bis(2,6-diisopropylphenyl)imidazol-2-ylidene) *via* the reaction of  $(i\text{Pr})\text{CuOtBu}$  with  $\text{HSi}(\text{OEt})_3$ , which also generated  $t\text{BuO-Si}(\text{OEt})_3$ .<sup>20</sup> Herein we report that the reaction of isocyanates with pinacolborane to generate boraformamides,  $\text{pinBN}(\text{R})\text{C}(=\text{O})\text{H}$ , with high chemoselectivity can be catalysed by the readily accessible, and stable precatalyst  $(i\text{Pr})\text{CuOtBu}$ .

We initially noted this reaction during our work on copper(I) catalysed hydrophosphination of isocyanates using phosphines generated *in situ* as a result of P–O bond reduction by pinacolborane.<sup>21</sup> When we added 2 mol%  $(i\text{Pr})\text{CuOtBu}$  to an equimolar mixture of triphenylphosphinite, pinacolborane (pinBH) and phenyl isocyanate we observed a number of products, including peaks we attributed to  $\text{pinBN}(\text{Ph})\text{C}(=\text{O})\text{H}$ . We initially considered that this selective monohydroboration may originate from the partial poisoning of the catalyst by the phosphines present. The reaction in the absence of phosphines, however, disproved this hypothesis. 2 mol% of  $(i\text{Pr})\text{CuOtBu}$  was added to an equimolar C<sub>6</sub>D<sub>6</sub> solution of pinBH and PhNCO and within 30 minutes both pinBH and the isocyanate were consumed, leaving only resonances attributed to  $\text{pinBN}(\text{Ph})\text{C}(\text{O})\text{H}$  and a minor resonance in the <sup>11</sup>B NMR spectrum at 21.7 ppm attributed to pinBOtBu. While the hydroboration of carbodiimides is a well-explored reaction,<sup>15</sup> the monohydroboration of isocyanates to give  $\text{pinBN}(\text{R})\text{C}(\text{O})\text{H}$  is underreported due to their propensity towards

**Scheme 1** Catalytic hydroboration of heterocumulenes (0.10 mmol) with pinBH (14.5  $\mu$ L, 0.10 mmol) and 2 mol% (IPr)CuOtBu in  $C_6D_6$  (0.5 mL), room temperature unless otherwise noted, NMR yields calculated based on duplicate  $^1H$  NMR spectra compared to a 1,3,5-(MeO)<sub>3</sub> $C_6H_3$  standard.

<sup>a</sup> Reaction was conducted at 80 °C for 16 h. <sup>b</sup> Evidence of other products with inconsistent conversions, see ESI.†

over-reduction to give methylamines.<sup>22</sup> Despite its seeming simplicity, no route has yet been described to access pinBN(Ph)C(O)H, with Nembenna reporting the reduction of only substituted arenes.<sup>13</sup>

To test if this hydroboration could be applied to other substrates, pinBH was reacted with a selection of heterocumulenes, in the presence of 2 mol% (IPr)CuOtBu (Scheme 1). Small alkyl groups were tolerated well under these reaction

conditions (**1a** and **1b** vs. **1c**). Under the conditions reported in Scheme 1, no hydroboration of isopropyl isocyanate was observed in the absence of (IPr)CuOtBu (see ESI.†).

Electron-donating aryl substitution also provided good conversions, albeit the very bulky 2,6-di-isopropylphenyl isocyanate required 16 hours at 80 °C to provide a 94% NMR yield (**1f**). 1,4-Di-isocyanatobenzene could be successfully dihydroborated in 71% yield (**1k**). Substitution of the aryl ring with electron withdrawing trifluoromethyl, cyano- and nitro-groups (**1h**, **1i**, **1j** respectively), however, provided limited conversion to the desired boraformamide and evidence of other products in the  $^1H$  and  $^{11}B$  NMR spectra (*vide infra*). Whilst carbodiimides were also viable substrates (**3a–c**), providing good to excellent yields, phenyl isothiocyanate provided limited conversion (**2a**). Only one example of isothiocyanate hydroboration exists in the literature.<sup>23</sup>

In the cases of alkyl and electron-rich aryl isocyanates the only observable organic product was the boraformamide. Moreover, even in the presence of excess pinacolborane, no evidence of further reduction was observed for phenyl isocyanate, instead extended reaction times provided evidence of catalyst death in the form of visible metallic copper. In contrast, electron-poor arenes provided evidence of other products which could be attributed to further reduction steps, including complete deoxygenation of the isocyanate fragment to produce the corresponding *N*-methylaniline. In the case of 4-cyanophenyl isocyanate and 3-nitrophenyl isocyanate, competing reduction of the other arene substituents were also observed providing complex product mixtures. Nevertheless, the formation of **1h** could be confirmed by the isolation of a single crystal of this material from a reaction mixture which was characterised by X-ray crystallography (Fig. 1). In contrast, reaction of 4-trifluoromethylphenyl isocyanate with one equivalent of pinBH provided only evidence of the boraformamide and methylaniline products in a ~6:1 ratio. Addition of 3 equivalents of isocyanate provided a 99% conversion to the boraformamide and 4-F<sub>3</sub>C-C<sub>6</sub>H<sub>4</sub>N(Bpin)CH<sub>2</sub>OBpin in a ~11:1 ratio. Heating of this reaction mixture to 80 °C for 16 hours

**Fig. 1** Molecular structure (30% probability ellipsoids) of 4-NC-C<sub>6</sub>H<sub>4</sub>N(Bpin)C(O)H (**1h**). Hydrogen atoms except on C8 are omitted for clarity. For metric parameters see ESI.†

provided 85% conversion to *N*-methyl-*N*-(pinacolbora)-4-trifluoromethylaniline.

Copper(i)-catalysed hydroboration of other unsaturated compounds in the literature generally occurs *via* the copper(i) hydride, with insertion of the unsaturated moiety into the Cu–H bond.<sup>24</sup> A similar mechanism was expected here, and stoichiometric reactions were used to garner evidence for this. The 6-Dipp ligand was used to ensure stability of the hydride intermediate.<sup>25</sup> Thus one equivalent of pinBH was added to a solution of (6-Dipp)CuOtBu to give a bright orange solution, characteristic of the copper(i) hydride. To this was added one equivalent of isopropyl isocyanate. <sup>1</sup>H and <sup>11</sup>B NMR spectroscopy revealed the formation of a single new 6-Dipp-containing species and pinBOtBu, and crystalline material precipitated from the reaction mixture. Recrystallisation of this material yielded colourless crystals suitable for XRD (Fig. 2). This confirmed the new complex to be (6-Dipp)CuN(iPr)C(O)H, resulting from the insertion of the isocyanate into the Cu–H bond. Addition of pinacol borane to this compound reformed (6-Dipp)CuH with concomitant elimination of pinBN(iPr)C(O)H.

With this insertion step experimentally validated, we turned our attention to understanding the specific mono-hydroboration observed with most isocyanates. In order to gain insight into the energetic parameters of this reaction, we undertook a DFT study at the BP86-D3BJ/BS2(benzene)//BP86/BS1 level of theory to investigate the proposed hydroboration pathway (Scheme 2). We initially focussed on the resting state of the copper catalyst.

Dimeric  $[(\text{IPr})\text{CuH}]_2$  was found to be  $-14.8 \text{ kcal mol}^{-1}$  lower in energy than the monomer,  $(\text{IPr})\text{CuH}$ , and conversion was

associated with a low barrier ( $\text{TS}_{[(\text{IPr})\text{CuH}]} 9.4 \text{ kcal mol}^{-1}$ ). In contrast, the bridged borohydride  $[(\text{IPr})\text{CuH}_2\text{Bpin}]$  was found to be slightly higher in energy ( $2.2 \text{ kcal mol}^{-1}$ ). Computational investigation of the interaction between either of these species and the isocyanate did not lead to a viable hydrocupration pathway.

We thus turned our attention to reactivity predicated on monomeric  $(\text{IPr})\text{CuH}$ , which has been widely implicated in catalysis, but with  $[(\text{IPr})\text{CuH}]_2$  proposed as the resting state. As shown, the stepwise formation of the hydride monomer,  $(\text{IPr})\text{CuH}$ , and subsequent insertion of the isocyanate proceeds with a high but accessible barrier of  $28.5 \text{ kcal mol}^{-1}$  (**TS1**) relative to  $[(\text{IPr})\text{CuH}]_2$ . This step is exergonic by  $-9.9 \text{ kcal mol}^{-1}$  towards **Int1** ( $-24.7 \text{ kcal mol}^{-1}$ ) and is likely to be essentially irreversible.  $\sigma$ -bond metathesis then proceeds with a barrier of  $15.4 \text{ kcal mol}^{-1}$  (**TS2**), associated but is slightly endergonic by  $2.9 \text{ kcal mol}^{-1}$  on forming the boraformamide product, **1a**, and reforming  $(\text{IPr})\text{CuH}$  ( $-21.8 \text{ kcal mol}^{-1}$ ). Dimerisation of the hydride to reform  $[(\text{IPr})\text{CuH}]_2$  ( $-36.6 \text{ kcal mol}^{-1}$ ), however, provides an energy decrease overall to these steps of  $-11.9 \text{ kcal mol}^{-1}$ . For the reaction to proceed to deoxygenation, as observed with most systems, **1a** could be expected to be further hydrocuprated to a borylated aminolate, **Int2**, which could then proceed in a stepwise fashion to an *N*-methylamine with net elimination of a borate ester. Investigation of this step from the  $[(\text{IPr})\text{CuH}]_2$  resting state indicated that its barrier is  $33.5 \text{ kcal mol}^{-1}$  (**TS3**), larger than that of the first insertion and  $\sigma$ -bond metathesis steps suggesting this step is kinetically less accessible especially as this reaction is performed at room temperature. This insertion product, **Int2**, is also higher in energy than the resting state and **1a** by  $11.2 \text{ kcal mol}^{-1}$ . We thus posit that the source of selectivity in this reaction is that the first step of overreduction is both kinetically disfavoured and significantly higher in energy than dimerization of the copper(i) hydride in the presence of **1a**. The copper(i) hydride dimer is also well-established to show limited stability, converting to free IPr, copper metal and hydrogen.<sup>20</sup>

With a model for the selective mono-hydroboration proposed we turned our attention to the cases where over-reduction was observed, calculating a comparative pathway for 4-cyano-phenyl isocyanate. The initial reduction steps show a generally similar pattern to the isopropyl isocyanate. An accessible and stabilising initial hydrocupration is followed by a slightly uphill Cu–N/B–H  $\sigma$ -bond metathesis except when dimerization is considered. The second hydrocupration shows a significant deviation. In contrast to the isopropyl case, where the calculated barrier was  $33.5 \text{ kcal mol}^{-1}$  (**TS2'**), for the 4-cyanophenyl isocyanate, this second hydrocupration is only associated with an overall barrier of  $26.3 \text{ kcal mol}^{-1}$  (**TS3'**) relative to  $[(\text{IPr})\text{CuH}]_2$ , much more accessible and commensurate with that for the first hydrocupration. Moreover, the resultant borylated aminolate, **Int2'**, shows similar stability to **1a** and  $[(\text{IPr})\text{CuH}]_2$  (energy difference:  $0.4 \text{ kcal mol}^{-1}$ ). This ensures that the second hydroboration competes with dimer formation and consequent decomposition and contributes to the reduced selectivity observed for electron-poor arenes.

Scheme 2 Computed pathways (free energy,  $\text{kcal mol}^{-1}$ ) for the hydroboration of iPrNCO (black/red) and 4-NC-C<sub>6</sub>H<sub>4</sub>-NCO (blue) at the BP86-D3BJ//BS2(benzene)//BP86/BS1 level of theory. For full computational details see ESI.†

In conclusion, we have described a highly selective hydroboration system; the action of pinacol borane on a range of isocyanates gives, in most cases, only the boraformamide with (IPr)CuOtBu as a catalyst. A computational study implied that the origin of the selectivity is the barrier height to boracupration of the boraformamide, especially in competition with dimerization of the copper(i) hydride to form  $[(\text{IPr})\text{CuH}]_2$ . In the presence of electron rich isocyanates, the formation of this species was suggested to kinetically disfavour over-reduction thus producing the observed selectivity. In future, carefully designed reaction systems might leverage oligomerisation as a source of selectivity based on this work.
