## Reduction of SF<sub>5</sub>CF<sub>3</sub> via iridium catalysis: radical trifluoromethylation of aromatics†

Domenique Herbstritt and Thomas Braun \*\*\* \*\*

The greenhouse gas SF<sub>5</sub>CF<sub>3</sub> acts as CF<sub>3</sub> source for the photocatalytic trifluoromethylation of arenes on using [Ir(dtbbpy)(ppy)2]PF6 (4,4'di-tert-butyl-2,2'-dipyridyl, ppy = 2-phenylpyridine) as catalyst. The trifluoromethylation of C<sub>6</sub>D<sub>6</sub> in the presence of 1-octanol results in the concomitant generation of 1-fluorooctane, presumably by intermediate SF<sub>4</sub>.

The CF<sub>3</sub> group plays an important role in medicinal chemistry in part due to their ability to increase the lipophilicity of compounds, and thereby enhance the rate of absorption and transport of drugs across the blood-brain barrier. In 1963 Bedard et al. reported on the thermal homolysis of the trifluoromethyl derivatives CF<sub>3</sub>I, CF<sub>3</sub>Br, CF<sub>3</sub>Cl to achieve a radical trifluoromethylation of halobenzenes.<sup>2,3</sup> Silver trifluoroacetate and TiO2 as a photocatalyst were also used to form CF3 radicals in order to synthesize trifluoromethylated aromatics.4 Kamigata et al. demonstrated the trifluoromethylation of aromatics on using a ruthenium(II)phosphine complex as a catalyst and trifluormethanesulfonylchloride as CF3 source in a thermal reaction.<sup>5</sup> In 2011 MacMillan et al. published a photocatalytic trifluoromethylation of aromatics with [Ru(phen)<sub>3</sub>]Cl<sub>2</sub> (phen = phenanthroline) as catalyst again using F<sub>3</sub>CSO<sub>2</sub>Cl as a source for the trifluoromethyl group.<sup>6</sup> The research group of Hu et al. described a photochemical trifluoromethylation reaction in which an electron donor-acceptor complex between an aromatic thiophenolate anion and trifluoromethylphenylsulfone initiates a single electron transfer, and therefore the generation of CF<sub>3</sub> radicals. In other photocatalytic trifluoromethylations of aromatics CF<sub>3</sub>SO<sub>2</sub>Na<sup>8</sup> or trifluoromethanesulfonic anhydride<sup>9</sup> were used as trifluoromethyl radical source. Note also that in 2009 MacMillan et al. reported on an enantioselective trifluoromethylation of aldehydes via a photoredox process coupled with organocatalysis on using the Ir redox catalyst [Ir(dtbbpy)(ppy)<sub>2</sub>]PF<sub>6</sub>

Department of Chemistry, Humboldt-Universität zu Berlin, Brook-Taylor-Str. 2, 12489, Berlin, Germany. E-mail: thomas.braun@chemie.hu-berlin.de

(4,4'-di-tert-butyl-2,2'-dipyridyl, ppy = 2-phenylpyridine). In an reductive quenching cycle CF3I is being reduced to give a CF3 radical. 10 Furthermore, [Ir(dtbbpy)(ppy)2]PF6 was used in a photocatalytic approach for the trifluoromethylation of alkynes. 11 Note that apart from CF3 transfer other fluoroalkyl groups can be transferred as well via photocatalysis. 12

In the last few years the activation of the greenhouse gas SF<sub>6</sub> and its use as fluorinating agent has been studied extensively. 13-18 Conversions are often initiated by an electron transfer to SF<sub>6</sub> to yield SF<sub>6</sub><sup>-</sup>. The latter can either transform into a SF<sub>5</sub> radical and a fluoride or SF<sub>5</sub><sup>-</sup> and a fluoro radical. 16,17,19 Examples for the photochemical activation of SF<sub>6</sub> include the application of the photocatalysts [Ru(phen)<sub>3</sub>]Cl<sub>2</sub>,<sup>6</sup> 4,4-dimethoxybenzophenone<sup>15</sup> or [Ir(dtbbpy)(ppy)<sub>2</sub>]PF<sub>6</sub><sup>18</sup> The SF<sub>6</sub> derivative SF<sub>5</sub>CF<sub>3</sub> has also a high global warming potential and a long atmospheric life-time.<sup>20</sup> It is assumed that SF5CF3 is a breakdown product of SF6 in highvoltage equipment. The latter contains fluoropolymers which are sources for CF3 moieties that can react with SF5 radicals formed by high voltage discharges.<sup>20</sup> However, electron transfer to SF<sub>5</sub>CF<sub>3</sub> can result in the generation of SF5- and a CF3 radical. Thus, the formation of SF<sub>5</sub><sup>-</sup> has been observed in low-energy attachment experiments by mass spectrometry. 21,22 SF<sub>5</sub>CF<sub>3</sub> activation processes are rare and in solution only one example is known in the literature, to the best of our knowledge.<sup>14</sup>

In this contribution we report on an unprecedented trifluoromethylation of aromatic compounds by photocatalytic generation of CF<sub>3</sub> radicals from the greenhouse gas SF<sub>5</sub>CF<sub>3</sub>.

Irradiation of SF<sub>5</sub>CF<sub>3</sub> at a wavelength of 353 nm in C<sub>6</sub>D<sub>6</sub> in the presence of 4,4'-dimethoxybenzophenone as an organic photocatalyst (Scheme 1) led to the generation of small amounts of  $\alpha,\alpha,\alpha$ trifluorotoluene-d<sub>5</sub>. Similar, only traces of α,α,α-trifluorotoluene-d<sub>5</sub> were observed when 10-phenylphenothiazine (Scheme 1) was used to activate SF<sub>5</sub>CF<sub>3</sub>. However, irradiation of SF<sub>5</sub>CF<sub>3</sub> in the presence of the photoredox catalyst [Ir(dtbbpy)(ppy)<sub>2</sub>]PF<sub>6</sub> (Scheme 1), triethylamine and cesium carbonate with a 456 nm LED lamp for 16 h in  $C_6D_6$  yielded  $\alpha,\alpha,\alpha$ -trifluorotoluene- $d_5$  with a turnover number (TON) of 410 (TON are based on the concentration of the catalyst on using 1,4-difluorobenzene as internal standard) (Scheme 2). that without the presence of Et<sub>3</sub>N the conversion does not proceed. Attempts to use K<sub>2</sub>HPO<sub>4</sub> as an alternative base failed. Triethylamine and cesium carbonate in a ratio of 1:1 led to the highest turnover numbers. 19F NMR experiments revealed the presence of DF when no Cs<sub>2</sub>CO<sub>3</sub> was present. Using 4-methoxydiphenylamine and Cs<sub>2</sub>CO<sub>3</sub> as bases in a ratio of 1:1 led to a decrease of the TON to 26. Note that with the photoredox catalyst [Ru(bpy)<sub>3</sub>](PF<sub>6</sub>)<sub>2</sub> or [Ir(dFppy)<sub>3</sub>] lower TONs of 28 and 46, respectively, were observed in the presence of NEt<sub>3</sub> and Cs<sub>2</sub>CO<sub>3</sub> in a ratio of 1:1. Reactions with [Ir(dtbbpy)(ppy)<sub>2</sub>]PF<sub>6</sub> as catalyst with only stoichiometric amounts of benzene in acetonitrile or dichloroethane as solvents gave  $\alpha,\alpha,\alpha$ trifluorotoluene-d5 only in very low yield. Mainly the generation of trifluoromethane and other minor unidentified products was observed (ratio CF<sub>3</sub>H to PhCF<sub>3</sub>: 71:1 in acetonitrile, 52:1 in dichloroethane). With dichloromethane and tetrahydrofurane as

Scheme 2 Trifluoromethylation of arenes on using [Ir(dtbbpy)(ppy)<sub>2</sub>]PF<sub>6</sub> as photoredox catalyst.

solvents in the presence of stoichiometric amounts of benzene did not lead to any product formation.

To expand the scope of the conversions, pyridine, anisole, 1,2,3,4-tetrafluorobenzene and deuterated toluene (Scheme 2) were studied towards a photochemical trifluoromethylation on using a stock solution of [Ir(dtbbpy)(ppy)<sub>2</sub>]PF as photocatalyst. All the conversions were run with the substrate as solvent. Selectivities can be explained when considering that the CF<sub>2</sub> radical shows an electrophilic character.<sup>2,6</sup> Transformations of toluene-d<sub>8</sub> and anisole resulted mainly in the formation of isomers with the CF<sub>3</sub> group in the ortho or para position. Pyridine gives mainly the ortho-product, but also considerable amounts of metatrifluoromethylpyridine. Minor amounts of trifluoromethane were also detected. 1,2,3,4-Tetrafluorobenzene however did not show any reactivity under the standard conditions. The trifluoromethylated aromatics were characterized by their signals in the <sup>19</sup>F NMR spectra for the CF<sub>3</sub> groups in the para, meta or ortho positions as well as by GC-MS.

Mechanistically, it can be presumed that after irradiation at 456 nm a single electron transfer SET from the photocatalytic system to SF<sub>5</sub>CF<sub>3</sub> leads to the SF<sub>5</sub>CF<sub>3</sub> radical anion (Scheme 3). As mentioned above, the subsequent trifluoromethylation does not proceed without the presence of NEt3 as reductant. Thus, NEt<sub>3</sub> can reduce the photoexcited species [Ir(dtbbpy)(ppy)<sub>2</sub>]<sup>+</sup>\* generated after excitation of [Ir(dtbbpy)(ppy)<sub>2</sub>]<sup>+</sup> in a reductive quenching cycle (Scheme 3). This step is followed by the SET from the reduced [Ir(dtbbpy)(ppy)<sub>2</sub>] ( $E_{pc} = -1.51 \text{ V } \nu \text{s. SCE}$ )<sup>23,24</sup> to SF<sub>5</sub>CF<sub>3</sub>. Alternatively,  $[Ir(dtbbpy)(ppy)_2]^{+*}$  ( $E_{pc} = -0.96 \text{ V } \nu s$ . SCE)<sup>23,24</sup> reduces SF<sub>5</sub>CF<sub>3</sub> and the generated [Ir(dtbbpy)(ppy)<sub>2</sub>]<sup>2+</sup> is then reduced by NEt3 in an oxidative quenching cycle. Note that photocatalytic conversions of [Ir(dtbbpy)(ppy)<sub>2</sub>]<sup>+</sup> have a tendency to proceed via a reductive quenching cycle. 10,25 However, the SF<sub>5</sub>CF<sub>3</sub> radical anion then decomposes to give a CF<sub>3</sub> radical and SF<sub>5</sub><sup>-</sup>.<sup>22,26</sup> The SF<sub>5</sub><sup>-</sup> anion is not very stable and furnishes SF<sub>4</sub> and fluoride. 16,27 The CF<sub>3</sub> radical reacts then with benzene forming a cyclohexadienyl radical. The generation of the latter in trifluoromethylation reactions has been proposed by Kamigata et al.<sup>5</sup> and others.<sup>6,9,28</sup> Oxidation of the cyclohexadienyl

Scheme 4 Quenching of the photocatalytic trifluoromethylation with TEMPO or 1-octanol (a and b); generation of  $Ph_3P = S$  after addition of PPh<sub>3</sub> to the reaction mixture (c).

radical by the NEt<sub>3</sub>•+ radical cation and subsequent deprotonation of the cyclohexadienyl cation by fluoride yields the trifluoromethylated aromatic product and NEt<sub>3</sub>·HF. <sup>2,6,9,29</sup> Alternatively, hydrogen atom abstraction HAT from the cyclohexadienyl radical would give the intermediate Et<sub>3</sub>NH<sup>+</sup>, and in the presence of fluoride the same products.<sup>23</sup> Cesium carbonate acts as an HF scavenger. There is no indication for the formation of HD or H2 along with an iminium ion from the NEt3 radical. However, the observed generation of trifluoromethane in acetonitrile or dichloromethane can involve HAT from the solvent or the NEt<sub>3</sub>•+ radical. The latter is consistent with the fact that higher NEt<sub>3</sub> concentrations deliver more CF<sub>3</sub>H.

Furthermore, to confirm the intermediate formation of a CF<sub>3</sub> radical, TEMPO (2,2,6,6-tetramethylpiperidinyloxyl) was added to the photocatalytic trifluoromethylation reaction of C<sub>6</sub>D<sub>6</sub>, and indeed TEMPO inhibited the conversion (Scheme 3). However, after 96 h TEMPO-CF<sub>3</sub> as well as the  $\alpha,\alpha,\alpha$ -trifluorotoluene-d<sub>5</sub> were observed in a ratio of 1:2. The formation of SF<sub>4</sub> was not observed by low temperature NMR experiments, presumably because of the presence of Cs<sub>2</sub>CO<sub>3</sub>. Nevertheless, when the trifluoromethylation of C<sub>6</sub>D<sub>6</sub> was run in the presence of 1octanol in the generation of 1-fluorooctane was observed, which was identified by GC-MS and <sup>19</sup>F NMR spectroscopy (Scheme 4). The experiment suggests the deoxyfluorination of the alcohol by intermediate SF<sub>4</sub>.<sup>30</sup> Hence, trifluoromethylation steps can be coupled with the fluorination of an alcohol. However, under the UV irradiation SF<sub>4</sub> might also be further reduced yielding elemental sulfur, as it was also proposed by Nagorny et al. for the activation of SF<sub>6</sub> in the presence of the organophotocatalyst 4,4-dimethoxybenzophenone.15 Indeed, when PPh3 was added to the reaction mixture after the photolytic formation of C<sub>6</sub>D<sub>5</sub>CF<sub>3</sub>, the generation of small amounts of SPPh<sub>3</sub> (7) was observed after heating the reaction mixture for two hours at 60 °C, which might be due to the presence of sulfur (Scheme 4).

In conclusion, a catalytic photoredox process for the activation of the greenhouse gas SF5CF3 and a concomitant trifluoromethylation of aromatics were reported. SF<sub>5</sub>CF<sub>3</sub> acts as source for CF<sub>3</sub> radicals and at the same time SF<sub>4</sub> and sulfur can be furnished. The former can be used for fluorination to couple the trifluoromehylation of aromatics with a fluorination of an alcohol. Note also that iridium photocatalyzed processes were applied for the defluorination of fluorinated organic substrates,<sup>31</sup> which was not observed for the described transformations.

Experiments, data collection (NMR and GC-MS) and analysing the data was performed by D. Herbstritt. The manuscript was drafted by D. Herbstritt. T. Braun supervised the work, designed the project and contributed to manuscript writing.
