# Highly selective CO<sub>2</sub> electrolysis in aqueous media by a water-soluble cobalt dimethyl-bipyridine complex†

Tomiko M. Suzuki,<sup>a</sup> Kengo Nagatsuka,<sup>b</sup> Takamasa Nonaka,<sup>a</sup> Yuichi Yamaguchi,<sup>b,c</sup> Naonari Sakamoto,<sup>a</sup> Takeshi Uyama,<sup>a</sup> Keita Sekizawa,<sup>a</sup> Akihiko Kudo<sup>\*b,c</sup> and Takeshi Morikawa<sup>\*a</sup>

**A water-soluble Co complex with dimethyl-bipyridine ligands reduced CO<sub>2</sub> to CO electrochemically with almost 100% selectivity at −0.80 V vs. NHE in an aqueous medium (pH 6.8) without an organic solvent. The reaction overpotential was 270 mV. A possible CO formation mechanism was discussed based on experiments and calculations.**

Reductive conversion of CO<sub>2</sub> into useful energy-rich chemicals using water and sustainable energy is a promising approach to ameliorating the fossil fuel shortage and mitigating global warming. Thus, the electrocatalytic CO<sub>2</sub> reduction reaction (CO<sub>2</sub>RR) to form C1 chemicals such as basic ingredients carbon monoxide (CO) and formic acid is an active research topic. CO is a desirable target product because it can be converted into various hydrocarbons *via* Fischer–Tropsch synthesis. Gaseous CO exhibits low solubility in aqueous media, making its collection easier than that of liquid products such as formic acid.

Molecular metal complexes are advantageous as catalysts because their properties can be controlled through manipulation of their metal–ligand interactions; some molecular complexes therefore exhibit high reaction selectivity toward CO<sub>2</sub>, especially in organic solvents with a sacrificial electron donor. The use of water molecules as electron donors, high CO<sub>2</sub> selectivity in aqueous solution, and a low overpotential for the CO<sub>2</sub>RR are all important requirements for a sustainable catalytic system. However, CO<sub>2</sub> reduction by complex catalysts dissolved in almost 100% water is challenging. Nonetheless, the literature contains a few reports on selective electrocatalytic or photocatalytic CO<sub>2</sub>RR by water-soluble metal complexes in a fully aqueous solution. Selective CO<sub>2</sub> reduction by water-soluble complex catalysts with macrocyclic ligands such as cyclam,

porphyrin, or their derivatives has been reported.<sup>1–5</sup> In addition, polypyridines such as 2,2′-bipyridine (bpy), 2,2′:6′,2′′-terpyridine (tpy), and phenanthroline (phen) are common ligands in coordination chemistry and molecular catalysis because they generally construct stable, well-defined complexes. A water-soluble *fac*-[Re(CH<sub>2</sub>OH)–OH<sub>2</sub>]<sup>+</sup> (*fac*-[Re(4,4′-dihydroxymethyl-2,2′-bipyridine)(CO)<sub>3</sub>(OH<sub>2</sub>)]<sup>+</sup>) has been reported to show electrochemical CO production with 95% selectivity at −1.1 V vs. normal hydrogen electrode (NHE) in an aqueous solution at pH 6.9.<sup>6</sup> More abundant metal elements are also desired as central metal species that drive an aqueous CO<sub>2</sub>RR in terms of lowering the cost and reducing CO<sub>2</sub> emissions in the overall system life-cycle.<sup>7–9</sup> [Mn(bpy(COOH)<sub>2</sub>)(CO)<sub>3</sub>Br] (bpy(COOH)<sub>2</sub>: 4,4′-dicarboxy-2,2′-bipyridine) and [Cu(phen)<sub>2</sub>]<sup>2+</sup> complexes have also been reported as water-soluble catalysts with a faradaic efficiency (FE) of 65% and ~60%, respectively, for CO formation for the electrochemical CO<sub>2</sub>RR (Table S1, ESI†).<sup>10,11</sup>

Water-soluble Co complexes with bpy ligands have been reported as electro- and photocatalysts for hydrogen evolution,<sup>12</sup> whereas their ability to function as a CO<sub>2</sub> reduction catalyst in aqueous solution has not yet been demonstrated. In the case of the tpy ligand, [Co(tpy)<sub>2</sub>]<sup>2+</sup> ([Co-tpy]) has been reported to produce CO and H<sub>2</sub> electrochemically in a dimethyl-formamide (DMF)/H<sub>2</sub>O (95/5 vol%) mixed solvent.<sup>13</sup> In the case of the bpy ligand, [Co(bpy)<sub>3</sub>]<sup>2+</sup> ([Co-bpy]) or [Co(dmbpy)<sub>3</sub>]<sup>2+</sup> ([Co-dmbpy]), dmbpy: 4,4′-dimethyl-2,2′-bipyridine) has been shown to promote the CO<sub>2</sub>RR to produce CO and H<sub>2</sub> under visible-light irradiation when used in combination with a photosensitizer or a semiconductor photocatalyst in an acetonitrile (MeCN) or MeCN/H<sub>2</sub>O mixture containing sacrificial electron donor reagents.<sup>14–17</sup> We recently adopted a water-soluble [Co-dmbpy] (Fig. 1a) for Z-schematic (two-step photoexcitation) photocatalysis for the CO<sub>2</sub>RR in an aqueous suspension with two coexisting semiconductors (BiVO<sub>4</sub> for water oxidation and (CuGa)<sub>0.3</sub>Zn<sub>1.4</sub>S<sub>2</sub> for the CO<sub>2</sub>RR).<sup>18</sup> The system demonstrated 98% CO selectivity (against 2% H<sub>2</sub>) and 1740 μmol-CO was produced using 12 μmol [Co-dmbpy] under visible-light irradiation (wavelength > 420 nm). The [Co-dmbpy] behaved as a

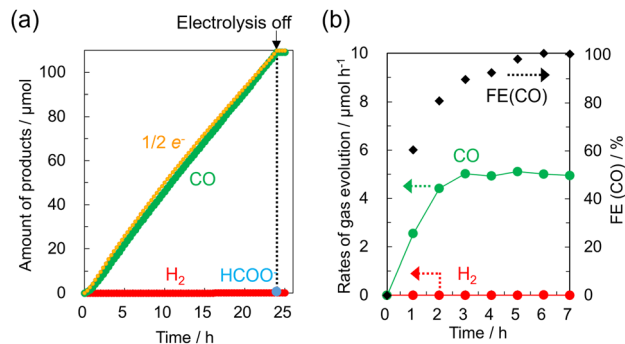

**Fig. 1** (a) Chemical structure of Co complexes with various polypyridine ligands and NO<sub>3</sub><sup>-</sup> counter anions (dmbpy: 4,4'-dimethyl-2,2'-bipyridine, bpy: 2,2'-bipyridine, dmbpy: 4,4'-dimethoxy-2,2'-bipyridine, tpy: 2,2':6',2'-terpyridine). (b) CV curves for [Co-dmbpy] (0.3 mmol L<sup>-1</sup>) in an aqueous NaHCO<sub>3</sub> (0.1 mol L<sup>-1</sup>) solution bubbled with CO<sub>2</sub> (red, pH 6.8) or Ar (blue, adjusted to pH 6.8).

redox-shuttle electron mediator for the two coexisting semiconductors. Furthermore, experiments and calculations strongly suggested that the [Co-dmbpy] acted as a highly selective cocatalyst for CO generation by receiving electrons from (CuGa)<sub>0.3</sub>Zn<sub>1.4</sub>S<sub>2</sub>.<sup>18</sup> However, the ability of the CO<sub>2</sub>RR with unusually high selectivity over [Co-dmbpy] in an aqueous solution has not been clarified, even electrochemically.

In this communication, the electrochemical CO<sub>2</sub>RR over the water-soluble [Co-dmbpy] was investigated. The experiments clarified that [Co-dmbpy] reduced CO<sub>2</sub> to CO with nearly 100% selectivity at a low potential of -0.80 V vs. NHE (pH 6.8, -0.40 V vs. reversible hydrogen electrode (RHE)), and further discussed the CO<sub>2</sub>RR mechanism in combination with calculation.

Water-soluble divalent Co complexes [Co-R<sub>1</sub>bpy], which have various substituents R<sub>1</sub> at the 2,2' position of the bpy ligand, and [Co-tpy], which has the tpy ligand (Fig. 1a), were synthesized.<sup>18</sup> Fig. 1b shows a current-voltage (cyclic voltammogram (CV)) curve for [Co-dmbpy] (0.3 mmol L<sup>-1</sup>) recorded in an aqueous NaHCO<sub>3</sub> (0.1 mol L<sup>-1</sup>) solution bubbled with CO<sub>2</sub> or Ar where carbon paper (CP) and Pt wire were used as working and counter electrodes, respectively. An H-shaped two-compartment reactor separated by a Nafion membrane was used (Fig. S1, ESI†). In the CV curve under a CO<sub>2</sub> atmosphere (red line), a small first reduction wave from about -0.4 V vs. NHE (pH 6.8) involving a valence change of the Co ion and a larger second reduction wave from -1.0 V vs. NHE was observed. This second reduction wave is considered as the CO<sub>2</sub> reduction current over the complex. On the other hand, the Ar atmosphere (blue line, in the absence of CO<sub>2</sub>) shows a similar CV curve, but the current values for the two reduction waves are lower than for the CO<sub>2</sub> atmosphere, especially the first reduction wave, which yields very small current. We focused on this first reductive peak and performed CO<sub>2</sub> electrolysis at -0.85 V vs. NHE for 24 h. A continuous reaction current of around -0.26 mA was generated (Fig. S3, ESI†). Fig. 2 shows the time-courses of the reduction products and faradaic efficiency (FE) for CO over [Co-dmbpy]. CO was predominantly produced, with trace amounts of H<sub>2</sub> and formic acid, whereas other gaseous species such as methane were not detected. The

**Fig. 2** CO<sub>2</sub> electrolysis of [Co-dmbpy] (0.3 mmol L<sup>-1</sup>) in an aqueous NaHCO<sub>3</sub> (0.1 mol L<sup>-1</sup>, 120 mL) solution at -0.85 V vs. NHE (pH 6.8) under CO<sub>2</sub> flow (1 atm). (a) Time-course of the total product amounts of CO and H<sub>2</sub> (the HCOO<sup>-</sup> content in the solution was measured at 24 h); 1/2 e<sup>-</sup> represents the theoretical total amount of two-electron reduction products calculated from the current observed at 100% current efficiency. (b) Time-dependent rates of initial CO<sub>2</sub> electrolysis for gas evolution and the faradaic efficiency (FE) for CO.

CO generation rate stabilized at a value of ~5 μmol h<sup>-1</sup> after the induction period for 3 h, with the FE for CO formation reaching almost 100% after 5 h of electrolysis (Fig. 2b). As shown in Fig. 2a, the amount of CO (green) produced increased almost linearly, approximately consistent with the ideal value calculated from the number of electrons measured (orange) for the two-electron reduction reaction. The CO selectivity among the total reduction products (CO, H<sub>2</sub>, and HCOO<sup>-</sup>) in 24 h reached 99.8%. The turnover number was 3.0, suggesting that this CO<sub>2</sub>RR was catalytic. When electrolysis was terminated, the formation of gas-phase components quickly ceased. These results show that a stable and highly CO<sub>2</sub>-selective catalyst originated from [Co-dmbpy] after a certain induction time. No reduction products were detected in electrolysis under the same conditions (-0.85 V vs. NHE, pH 6.8) in an Ar atmosphere (Fig. S4, ESI†), suggesting that CO formation is due to CO<sub>2</sub> reduction. In the UV-Vis spectrum of the CO<sub>2</sub> electrolysis solution, the peaks originating from π-π\* transitions of the Co complex showed almost no change between before and after 24 h of electrolysis, suggesting that the Co component was still present as a water-soluble complex in the solution even after the CO<sub>2</sub>RR (Fig. S5, ESI†). No evidence originating from heterogeneous species of Co components was detected on the CP electrode after 24 h of electrolysis, suggesting that the homogeneous species in the solution were driven as catalysts (Fig. S6 and S7, ESI†). From CO<sub>2</sub> electrolysis at different potentials, the overpotential for CO generation was estimated to be 270 mV relative to the theoretical value<sup>19,20</sup> (Table S1, entry 1 and Fig. S8, ESI†). Thus, [Co-dmbpy] achieved greater CO selectivity at lower potentials during CO<sub>2</sub> electrolysis than previously reported water-soluble molecular catalysts with polypyridine ligands (Table S2, ESI†). The CO selectivity varied significantly with the applied potential. For example, in the CO<sub>2</sub> electrolysis at -1.3 V vs. NHE (at pH 6.8), near the second reductive peak in the CV, competitive H<sub>2</sub> production was more predominant than CO production (Table S1, entry 4 and Fig. S9, ESI†). This result indicates that the CO<sub>2</sub>RR proceeds at a more positive potential

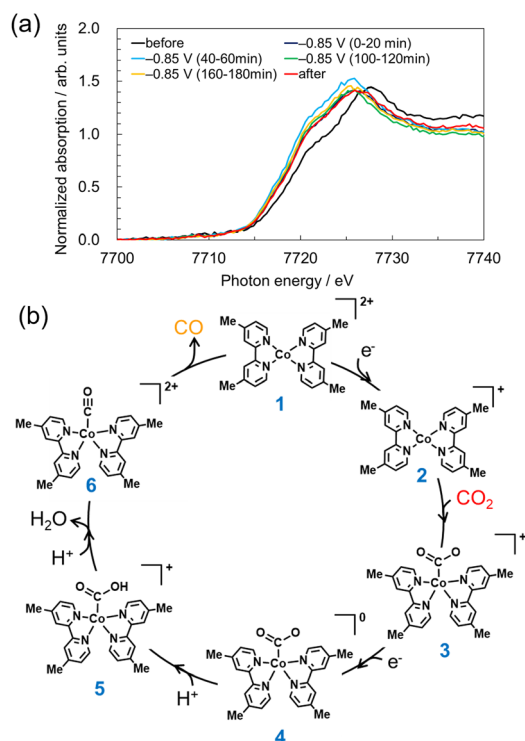

than that for H<sub>2</sub> production over [Co-dmbpy], despite the reaction occurring in an aqueous medium, as shown in the CV curves acquired under Ar and CO<sub>2</sub> (Fig. 1b).

To measure the change in the electronic state of Co in the aqueous solution at the cathode side, we carried out *operando* X-ray absorption spectroscopy (XAS) measurements *via* a fluorescence detection method (Fig. S2, ESI†). XAS measurements of Co complexes in such a dilute (0.5 mmol L<sup>-1</sup>) aqueous solution have not been reported. As shown in the Co K-edge X-ray absorption near edge structure (XANES) spectra originated from [Co-dmbpy] in Fig. 3a, immediately after a potential was applied (as an integrated signal for 0–20 min), the energy position of half-value of the normalized absorbance of the Co K-edge energy shifted negatively by 1.5 eV and the profile was stabilized even after electrolysis for 3 h. Another *operando* setup that allowed ~90% of Co K-edge X-ray signal to be attributed to the CP vicinity also yielded an XANES peak shift similar to that in Fig. 3a (Fig. S10 and S11, ESI†). These significant shifts are due to electron injection into Co complexes at -0.85 V vs. NHE, which might accompany a structural change to an active catalyst. Fig. 3b shows the proposed mechanism for estimating the electrochemical CO<sub>2</sub>RR by [Co-dmbpy] based on the density functional theory (DFT) calculations. The calculations suggested that a ligand-decoordinated species of [Co(dmbpy)<sub>2</sub>]<sup>2+</sup> (**1**) is formed as an active monomer catalyst by the decooordination of one dmbpy

ligand in [Co-dmbpy]. The energy diagram results based on the calculations for the two-coordinated complex (Fig. S12, ESI†) indicate that the highest energy barrier in the scheme of Fig. 3b is the process from **2** → **3** (CO<sub>2</sub> coordination), which is the rate-limiting step in the overall CO<sub>2</sub>RR. Therefore, it is considered that the -1.5 eV shift in the *operando* XANES spectra is attributable mainly to the active species **2**.

To verify the above hypothesis, we synthesized a pseudo-two-coordinate complex by mixing Co<sup>2+</sup> and twice the amount (equivalent) of dmbpy (hereafter, [Co/dmbpy = 1/2]), and we performed CO<sub>2</sub> electrolysis using it as a catalyst (Fig. S13–S15, ESI†). The induction period for CO formation by [Co/dmbpy = 1/2] was reduced to less than half that for the three-coordinated [Co-dmbpy] (Fig. S15, ESI†). These results suggest that the active species could be the two-coordinated species and the three-coordinated species is most likely a pre-catalyst.

Table 1 summarizes the results of the electrochemical CO<sub>2</sub>RR for three types of Co complexes having bpy-based ligands with different electron-donating substituents, [Co-tpy], and Co<sup>2+</sup> ions but without any ligands, as measured at -0.85 V vs. NHE for 6 h in NaHCO<sub>3</sub> aqueous solution (the corresponding structures are shown in Fig. 1a). First, in the case of an aqueous NaHCO<sub>3</sub> solution with no Co components, the generation rates for CO and H<sub>2</sub> at 6 h were very low: 0.54 and 0.28 μmol h<sup>-1</sup>, respectively (entry 8). These low rates were attributed to the reaction at the bare CP electrode as previously reported.<sup>11</sup> Only hydrogen was produced by Co<sup>2+</sup> ions without ligands preferred for CO<sub>2</sub> adduct formation (entry 7), indicating that the Co complexes function as a CO<sub>2</sub>RR catalyst. By contrast, the [Co-dmbpy] produced CO and H<sub>2</sub> rates of 5.13 and 0.01 μmol h<sup>-1</sup>, respectively, along with a small amount (0.1 μmol) of HCOO<sup>-</sup>; the selectivity toward CO among the total amount of products reached 99.6%, and the catalyst even suppressed H<sub>2</sub> generation at the carbon substrate (entry 1). [Co-bpy] and [Co-dmobpy] (dmobpy: 4,4-dimethoxy-2,2-bipyridine) produced CO at rates of 2.01 and 3.72 μmol h<sup>-1</sup> with CO

**Fig. 3** (a) *Operando* Co K-edge XANES spectra of 0.5 mmol L<sup>-1</sup> [Co-dmbpy] measured at open circuit (OC) voltage (before: black), CO<sub>2</sub> electrolysis (-0.85 V vs. NHE at pH 6.8), and after the electrolysis measured at OC voltage (after: red) measured in an aqueous 0.1 mol L<sup>-1</sup> NaHCO<sub>3</sub> solution bubbled with CO<sub>2</sub>. (b) Proposed electrocatalytic reduction mechanism for CO<sub>2</sub> to CO by two-coordinated complex **1** in an aqueous solution based on DFT calculation.

**Table 1** CO<sub>2</sub> electrolysis of 0.3 mmol L<sup>-1</sup> Co compound in an aqueous NaHCO<sub>3</sub> solution at -0.85 V (vs. NHE at pH 6.8) for 6 h<sup>a</sup>

Entry	Co compound	Current, 6 h/mA	Rate of products, 6 h/μmol h <sup>-1</sup>		CO selectivity/% <sup>b</sup>
			CO	H <sub>2</sub>	
1	[Co-dmbpy]	-0.26	5.13	0.01	99.6
2	[Co-tpy]	-0.16	0.73	0.52	57.2
3	[Co-bpy]	-0.12	2.01	0.19	86.8
4	[Co-dmobpy]	-0.21	3.72	0.11	95.8
5	[Co(bpy) <sub>3</sub> ]Cl <sub>2</sub> <sup>c</sup>	-0.11	1.64	0.14	87.1
6	[Co(bpy) <sub>3</sub> ]Cl <sub>3</sub> <sup>d</sup>	-0.11	1.43	0.16	92.6

8	None	-0.055	0.54	0.28	65.9

<sup>a</sup> Carbon paper, Ag/AgCl, and Pt wire were used as working, reference, and counter electrodes, respectively. The pH of the 0.3 mmol L<sup>-1</sup> Co compound/aqueous NaHCO<sub>3</sub> (0.1 mol L<sup>-1</sup>) solution under CO<sub>2</sub> (1 atm) was approximately 6.8. Electrolysis was performed for 6 h, and the production rate at 6 h is shown. <sup>b</sup> Calculated from the rate of CO generation in relation to the total amount of reduced products (CO, H<sub>2</sub>, and HCOO<sup>-</sup>) for 6 h. <sup>c</sup> Commercial product; [Co(III)(bpy)<sub>3</sub>]Cl<sub>2</sub>·5H<sub>2</sub>O. <sup>d</sup> Commercial product; [Co(III)(bpy)<sub>3</sub>]Cl<sub>3</sub>·4H<sub>2</sub>O.

selectivities of 86.8% and 95.8%, respectively (entries 3 and 4). Commercially available complexes [Co(II)-bpy] and [Co(III)-bpy] with Cl<sup>−</sup> as the counter ion (entries 5 and 6) also exhibited activities similar to that for the synthesized [Co(II)-bpy] with NO<sub>3</sub><sup>−</sup> as the counter ion (entry 3). In particular, [Co-dmbpy] and [Co-dmbpy] with electron-donating ligands on bpy yielded high CO selectivity greater than 95%. This result is consistent with the results of the DFT calculations: the electron-donating groups increase the electron density at the Co center, resulting in stronger bonding with CO<sub>2</sub> and promoting the CO<sub>2</sub>RR.<sup>18</sup> In the case of [Co-tpy], the rate of CO generation was 0.73 μmol h<sup>−1</sup> and the CO selectivity was 57.2%, which was inferior to the performance of Co complexes with bpy-based ligands (entry 2). This result is consistent with the observation that the Z-schematic CO<sub>2</sub>RR rate using the [Co-tpy] was low in a previous study.<sup>21</sup> [Co-tpy] might require much more negative potential to activate by decoordination of a tpy ligand, as suggested in a previous study that included an experiment conducted in DMF-H<sub>2</sub>O containing tetrabutylammonium perchlorate (TBAP) electrolyte.<sup>13</sup>

We here discuss the reason why CO<sub>2</sub> electrolysis of an aqueous Co complex solution occurred even at a low potential equivalent to −0.80 V vs. NHE. With respect to the mechanism of the lowered CO<sub>2</sub>RR potential over the Co porphyrin, DFT calculations suggest that water facilitated CO<sub>2</sub> reduction through a concerted pathway involving a hydrated metal complex.<sup>22</sup> DFT calculations and experiments have revealed that a reaction at the Mn-bpy, in harmony with metal cations and the carbon substrate, changes the CO<sub>2</sub>RR from an endothermic to an exothermic reaction.<sup>8,23</sup> In Re complexes, a mechanism due to dimerization has been proposed for the formation of CO in CO<sub>2</sub> reduction at high potential regions based on the one-electron pathway, which may also be the case in this system, but it is not evident.<sup>6</sup> Further detailed mechanistic analyses are important, and progress based on the investigations is expected for the present water-soluble [Co-dmbpy] system operating at the low potential regions.

The present [Co-dmbpy] yields CO with nearly 100% selectivity at a low potential of −0.80 V vs. NHE (pH 6.8). In the Z-schematic CO<sub>2</sub>RR photocatalysis, [Co-dmbpy] was coupled with the (CuGa)<sub>0.3</sub>Zn<sub>1.4</sub>S<sub>2</sub> semiconductor to produce CO with 98% selectivity under visible-light irradiation.<sup>18</sup> The conduction-band minimum (CBM) of (CuGa)<sub>0.3</sub>Zn<sub>1.4</sub>S<sub>2</sub> is located at a substantially more negative position (−1.66 V vs. NHE at pH 5.9). In a femtosecond transient spectroscopy study of a hybrid photocatalyst composed of an N-doped Ta<sub>2</sub>O<sub>5</sub> (N-Ta<sub>2</sub>O<sub>5</sub>) semiconductor linked with a Ru complex having bpy ligands [Ru-bpy], electron injection to the [Ru-bpy] not only from the CBM but also *via* shallow traps of the N-Ta<sub>2</sub>O<sub>5</sub> semiconductor was confirmed.<sup>24</sup> Thus, electron injection from shallow traps of (CuGa)<sub>0.3</sub>Zn<sub>1.4</sub>S<sub>2</sub> to the two-coordinate Co complex is also expected to produce CO (Fig. S16, ESI†). Because of the low overpotential for the CO<sub>2</sub>RR over the [Co-dmbpy] complex, sufficient room exists to apply it to various semiconductors to construct an efficient photosystem.<sup>20,25</sup> This possibility warrants further study in the near future.

In summary, a water-soluble Co(II) complex with dimethylbipyridine ligands functioned as an unparalleled electrocatalyst to drive the CO<sub>2</sub>RR in an aqueous hydrogen carbonate solution

bubbled with CO<sub>2</sub>. CO<sub>2</sub> reduction to CO occurred at a low potential of −0.80 V vs. NHE (pH 6.8) with a CO selectivity approaching 100%. Because the activity emerges in an aqueous solution without any organic solvents, it is beneficial to CO<sub>2</sub> reduction setups that use water as an electron donor in electrocatalysis and photocatalysis.

The *operando* XAFS data were acquired at the BL33XU beamline at the SPring-8 facility, with the approval of the Japan Synchrotron Radiation Research Institute (JASRI) (Proposal No. 2021A7038, 2021B7038, 2022A7038 and 2022B7038). AK thanks KAKENHI, Grants-in-Aid for Scientific Research (A) 23H00248, for financial support. The authors wish to thank Mr Makoto Kondo for experimental assistance and Dr Shunsuke Sato, Dr Masataka Ohashi, Dr Takeo Arai, and Mr Koutaro Wada for useful discussions.
