## Pillared MOFs: structure and ring opening polymerization of cyclic esters†

Yi Gong,<sup>a</sup> Fei Chen,<sup>a</sup> Jethro Beamish-Cook,<sup>a</sup> Mark R. J. Elsegood,<sup>b</sup> Max Derbyshire,<sup>b</sup> Oliver Rowe<sup>c</sup> and Carl Redshaw<sup>b</sup>  

The solvothermal reaction of  $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  with 5-aminoisophthalic acid and 4,4'-bipyridyl (4,4'-bipy)0.5]-DMF)<sub>n</sub> (**1**-DMF), but with DMF here (rather than H<sub>2</sub>O as previously): an analogous reaction using the related 4,4'-azopyridine (4,4'-azopy) in place of 4,4'-bipyridyl afforded the structurally related framework {[Zn(5-AIP)(4,4'-azopy)0.5]-0.75DMF)<sub>n</sub> (**2**-0.75DMF). Similar solvothermal reactions of  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ ,  $\text{Mn}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  and  $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  with 5-aminoisophthalate and the potential linkers 4,4'-bipy, 2-di(4-pyridyl)ethylene (DPE), and 4,4'-azopy afforded the porous 3-D structures {[Co<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub>(5-AIP)(4,4'-bipy)<sub>2</sub>·2EtOH)<sub>n</sub> (**3**-2EtOH), {[Co(5-AIP)(DPE)]·2DMF)<sub>n</sub> (**4**-2DMF), {[Co(5-AIP)(4,4'-azopy)]·2DMA)<sub>n</sub> (**5**-2DMA), {[Mn(5-AIP)(4,4'-bipy)]·2DMA)<sub>n</sub> (**6**-2DMA), {[Mn(5-AIP)(DPE)]·6DMF)<sub>n</sub> (**7**-6DMF), {[Mn(5-AIP)(4,4'-azopy)]·2.5DMF)<sub>n</sub> (**8**-2.5DMF), the previously reported {[Cd(5-AIP)(4,4'-bipy)]·3DMF)<sub>n</sub> (**9**-3DMF), {[Cd(5-AIP)(DPE)]·DMF)<sub>n</sub> (**10**), and {Cd(5-AIP)(4,4'-azopy)(DMF)<sub>n</sub> (**11**), with structures **4**–**10** bearing the same network topologies with metal atoms and 5-AIP ligands in sheets, bipy ligands acting as pillars, and solvent molecules of crystallisation located around the bipy ligands. The activated MOFs were employed as catalysts for the ring opening polymerization (ROP) of  $\epsilon$ -caprolactone and  $\delta$ -valerolactone. ROPs were conducted as melts, and under N<sub>2</sub> only **1** with  $\delta$ -VL (~93% conversion) was active. In the case of  $\epsilon$ -CL under air, all the systems were active with **1**, **2**, and **11** affording >90% conversion. Molecular weights ( $M_n$ ) were in the range 3760–17940 Da and the products formed were identified as both cyclic and linear PCL. For  $\delta$ -VL, the catalysts performed somewhat better, with all systems (except **8**) affording ~90% conversion or more under air. Molecular weights ( $M_n$ ) were in the range 2180–7940 and as for PCL, the products formed were identified as both cyclic and linear PCL.

## Introduction

MOFs with multiple types of organic linkers enable structural selectivity<sup>1</sup> and are useful in a variety of applications, including gas storage and separation, as well as catalysis.<sup>2–4</sup> The option to select linkers with different and possibly helpful functionalities increases the potential for the creation of multi-functional frameworks.<sup>5</sup> A wide range of linkers, including di- and tri-carboxylate anionic linkers, have been reported in the literature. The usage of linear dipyridyls in conjunction with benzene dicarboxylic acids is of special interest in this work. One of the most thoroughly investigated

systems is mixed-ligand systems using benzene-1,4-dicarboxylic acid (H<sub>2</sub>BDC) with a variety of neutral linkers.<sup>6–10</sup>

When compared with the previously reported 2-D structures,<sup>11</sup> those resulting from the use of the related ligand 5-aminoisophthalic acid (H<sub>2</sub>-5-AIP, Scheme 1) showed very similar binding modes, but with significant differences in the orientation of the 5-AIP units, resulting in 2-D sheets that can be further linked in to 3-D frameworks by the intercalation of linear dipyridyls. In a similar study, Jin *et al.* created lanthanide-based MOFs with mixed carboxylates of H<sub>2</sub>-5-AIP and oxalic acid.<sup>12</sup> Interestingly, these MOFs have a one-dimensional ladder-like chain, a two-dimensional layer, and a three-dimensional framework, among other structural features. These 2-D sheets were created by reacting zinc nitrate hexahydrate with H<sub>2</sub>-5-AIP under hydrothermal conditions, yielding 5-AIP units attached to three zinc centres in a mono-dentate form at each carboxylate function and at the amine function. Each zinc connects to three 5-AIP units, forming a tetrahedral coordination geometry with terminally coordinated water molecules.<sup>13</sup> Further metal–N bonds

**Scheme 1** MOF family of 5-aminoisophthalic acid ( $H_2$ -5-AIP) and pillaring linkers (top) 4,4'-bipyridyl; (middle) 4,4'-azopyridine and (bottom) 1,2-bis(4-pyridyl)ethylene.

should allow the coordination of neutral pillaring linkers above and below the plane of the sheets, resulting in extended 3-D structures, by extending the coordination sphere by the choosing of metal ions that preferentially adopt octahedral geometries.<sup>14,15</sup> These mixed-ligand MOFs also have good gas adsorption and separation characteristics. Chen *et al.* synthesized a zinc-based pillar-layer MOF that effectively separates  $CH_4$  and  $N_2$ .<sup>16</sup> In terms of  $CO_2$  uptake, a MOF constructed from  $Cu(NO_3)_2$  and 5-AIP, where the amino group of the 5-AIP helps form the pillars of the network, exhibited  $CO_2$  uptake capabilities (at 1 atm  $CO_2$ ) of  $79.94\text{ cm}^3\text{ g}^{-1}$  at 273 K and  $51.39\text{ cm}^3\text{ g}^{-1}$  at 298 K, and showed good selectivity for  $CO_2$  over  $N_2$ .<sup>17</sup> Selectivity for the adsorption of  $CO_2$  over  $CH_4$  was exhibited for a MOF derived from 5-AIP and 4,4'-azopyridine ( $M = Zn$ ).<sup>18</sup>

As a category of eco-friendly and biodegradable polymers, several studies have focused on the synthesis of polycaprolactone (PCL) and polyvalerolactone (PVL).<sup>19–21</sup> The most common method for producing PCL or PVL is ring opening polymerization (ROP).<sup>22</sup> In previous studies, both homogeneous and heterogeneous catalysts were utilised in the ROP of PCL, although homogeneous catalysts had a number of drawbacks.<sup>23</sup> The initial disadvantages are the low conversions and the low molecular weight. Another problem, which cannot be ignored, is the toxicity. It is difficult to

remove the residual metal in the polymer, which is undesirable when it is used as a biodegradable material. By comparison, heterogeneous catalysts have a more stable state and can be reused easily.<sup>24</sup> MOFs are a feasible alternative as heterogeneous catalysts because of their large specific surface area and porous structures.<sup>25,26</sup> However, there are only a few reports on employing MOFs as catalysts in the ROP of PCL or PVL.<sup>22–24,27</sup> As a result, we investigated these pillared MOFs as catalysts.

Despite the fact that a number of reports on related systems have appeared since we began this work, we have not only presented a number of new structural additions to the 5-AIP MOF derived family using 4,4'-bipyridyl, 4,4'-azopyridine, or 1,2-di(4-pyridyl)ethylene as pillars (Scheme 1), but have also screened systems for their potential to act as pre-catalysts for the ring opening polymerization (ROP) of cyclic esters. We note that the use of MOFs for catalysis is now attracting increased attention.<sup>28–30</sup>

## Results and discussion

### Zinc complexes

The synthesis of  $\{[\text{Zn}(5\text{-AIP})(4,4'\text{-bipy})_{0.5}]\cdot \text{DMF}\}_n$  (**1-DMF**) was achieved through the solvothermal reaction of zinc nitrate hexahydrate with  $\text{H}_2\text{-5-AIP}$  and 4,4'-bipyridyl in a DMF/

MeOH mixture. The resultant colourless, hexagonal prisms were of sufficient quality to perform single crystal X-ray diffraction. Structural elucidation of **1-DMF** revealed a hybrid covalent/H-bonded 3-dimensional network bearing the formula  $\{[\text{Zn}(5\text{-AIP})(4,4'\text{-bipy})_{0.5}]\cdot \text{DMF}\}_n$  (**1-DMF**). In this example, extended 2-D sheets formed by the bridging of three zinc centres by each 5-AIP unit, *via* monodentate bonds at each carboxylate moiety and an N donor bond from the amino group, are linked into bilayers by 4,4'-bipyridyl units, giving rise to tetrahedral coordination geometry around the zinc centres (Fig. 1, top). Extensive hydrogen bonding observed between the amine hydrogens of each sheet and the non-coordinated carboxylate oxygen of the neighbouring sheet gives the 3-dimensional structure (Fig. 1, bottom).

The PLATON squeeze procedure was used to model diffuse electron density in the voids of this framework, giving a total of 301 electrons per unit cell. This corresponds to a total of 8 DMF molecules per unit cell, or 1 per formula unit, which inhabit intersecting 1-dimensional channels situated parallel to the  $a$  and  $c$  axes, with no bonding interactions observed between the guest molecules and the framework. The binding motif observed here is analogous to the framework reported by Kongshaug *et al.*, namely  $\{[\text{Zn}(5\text{-AIP})(4,4'\text{-bipy})_{0.5}]\cdot 3\text{H}_2\text{O}\}_m$ , isolated from the reaction of  $\text{H}_2\text{-5-AIP}$  with 4,4'-bipyridyl and

**Fig. 3** Top: Diagram of  $\{[\text{Co}_2(\text{NO}_3)_2(5\text{-AIP})(4,4'\text{-bipy})_2]\cdot 2\text{EtOH}\}_n$ ,  $3\cdot 2\text{EtOH}$  showing the coordination environment around the metal centre. Bottom: Left: Diagram of the extended structure of  $3\cdot 2\text{EtOH}$  as viewed along the  $b$  axis. Chelated nitrate anions extend into the pores of the framework forming hydrogen bonds with guest ethanol molecules. Right: Diagram of the extended structure of  $3\cdot 2\text{EtOH}$  as viewed along  $c$  axis, showing the herringbone motif of coordinated  $4,4'$ -bipy units. Carbon, nitrogen, oxygen, cobalt, and hydrogen atoms are coloured brown, blue, red, dark blue, and pink, respectively.

zinc nitrate hexahydrate in a DMF/ $\text{H}_2\text{O}$  mixture; however no hydrogen bonding was observed between the bilayers.<sup>31</sup> Also reported were the analogous structures  $\{[\text{Zn}(5\text{-AIP})(\text{DPE})_{0.5}]\cdot 2.5\text{H}_2\text{O}\}_n$ ,  $\{[\text{Zn}(5\text{-AIP})(\text{DPA})_{0.5}]\cdot 2.5\text{H}_2\text{O}\}_n$  and  $\{[\text{Zn}(5\text{-AIP})(\text{DPP})_{0.5}]\cdot 3\text{H}_2\text{O}\}_n$  (where DPE = 1,2-di-4-pyridyl ethylene, DPA = 1,2-di-4-pyridylethane and DPP = 1,2-di-4-pyridylpropane). It is of particular interest that the use of neutral linkers of increasing length in this example does not have a profound effect on pore size. Due to the fixed orientation of the zinc tetrahedra on opposing walls of the bilayers, the longer dipyridyls are forced to adopt a bent conformation, and while this leads to a minor increase in the size of the small channels running parallel to the  $a$  axis, the large channels observed along the  $b$  axis exhibited dimensions of  $3.5 \times 6.7 \text{ \AA}^2$  in all four examples.

The preparation of  $\{[\text{Zn}(5\text{-AIP})(4,4'\text{-azopy})_{0.5}]\cdot 0.75\text{DMF}\}_n$  ( $2\cdot 0.75\text{DMF}$ ) was achieved using the same reaction conditions as  $1\text{-DMF}$ , but using  $4,4'$ -azopy. Orange prisms suitable for single crystal X-ray diffraction were formed on cooling, however due to a twinning component which could not be resolved the data collected were of sufficient quality to

only determine connectivity. Comparison of the collected powder X-ray diffraction pattern for this structure with the simulated pattern for **1** reveals distinct similarities in line spacing and intensity (Fig. 13). TGA and gas adsorption data also show similar behaviours. The framework, bearing the formula  $\{[\text{Zn}(5\text{-AIP})(4,4'\text{-azopy})_{0.5}]\cdot 0.75\text{DMF}\}_n$ , exhibits the same binding motif between the zinc centres and the organic linkers as  $1\text{-DMF}$ , with tetrahedrally coordinated zinc atoms forming bonds to two carboxylate oxygens from independent 5-AIP molecules, the amine nitrogen of a third 5-AIP molecule, and the pyridinyl nitrogen of a  $4,4'$ -azopy molecule (Fig. 2, top). Each 5-AIP molecule links three zinc centres *via* the monodentate coordination of each of the carboxylate groups and the amine nitrogen, forming infinite 2-D sheets observed in the  $b/c$  plane. The sheets are linked into pairs along the  $a$  axis by the coordination of the  $4,4'$ -azopy linker to zinc centres at each of the pyridinyl nitrogen atoms (Fig. 2, bottom, left).

Due to the quality of the data set, the amine hydrogen atoms could not be located, however the proximity of the

Fig. 4 Top: Diagram of  $\{[\text{Co}(5\text{-AIP})(\text{DPE})]\cdot 2\text{DMF}\}_n$ , 4-2DMF, showing the coordination environment around the  $\text{Co}^{2+}$  centre. The guest DMF molecules are located around the DPE linker. Bottom: Diagram of the extended structure of 4-2DMF as viewed along the  $b$  axis (left) and  $c$  axis (right). Guest DMF molecules are visible around the DPE linkers. Carbon, nitrogen, oxygen, cobalt, and hydrogen atoms are coloured brown, blue, red, dark blue, and pink, respectively.

Fig. 5 Left: Diagram of  $\{[\text{Co}(5\text{-AIP})(4,4'\text{-azopy})]\cdot 2\text{DMA}\}_n$  (5-2DMA), showing the coordination environment around the  $\text{Co}^{2+}$  nodes. Hydrogen atoms are omitted. Right: Diagram of the 2-D sheets in 5-2DMA showing the hydrogen bonding interactions, represented by dotted lines between the amine functions and carboxylate groups of neighbouring 5-AIP units.

$\text{N}(3)$  atoms to the  $\text{O}(2')$  and  $\text{O}(4')$  of neighbouring sheets ( $2.99 \text{ \AA}$ ) offers evidence of strong hydrogen bonding interactions between the bilayer sheets, giving a 3-D hybrid H-bonded/covalent network analogous to that of **1**. As with the examples reported by Kongshaug *et al.*,<sup>31</sup> the use of the longer, neutral, pillaring linker has little effect on the size of the large pores, in this example situated parallel to the  $b$  axis, with the spacing between the 4,4'-azopy molecule dictated by the distance between the zinc atoms in the  $[\text{Zn}(5\text{-AIP})]_n$  sheets. When viewed along the  $c$  axis, however, the narrowing of the small pores by the orientation of the 4,4'-azopy molecules is revealed (Fig. 2, bottom, right). Again, due to the quality of the data set, guest solvent molecules could not be resolved by point atom observations and were modelled as areas of diffuse electron density by the PLATON squeeze

Carbon, nitrogen, oxygen, and manganese atoms are coloured brown, blue, red, and rose red, respectively.

procedure, giving 3 DMF molecules located in two small voids per unit cell, equating to 0.75 DMF molecules per formula unit.

### Cobalt complexes

Solvothermal reactions of cobalt nitrate hexahydrate with  $\text{H}_2$ -5-AIP and the bipyridyls 4,4'-bipyridyl (4,4'-bipy) or 4,4'-azopyridine (4,4'-azopy) in a DMF/EtOH mixture afforded two metal organic frameworks of structural formulae  $\{[\text{Co}_2(\text{NO}_3)_2(5\text{-AIP})(4,4'\text{-bipy})_2]\cdot 2\text{EtOH}\}_n$  (3·2EtOH) and  $\{[\text{Co}(5\text{-AIP})(\text{DPE})]\cdot 3\text{DMF}\}_n$  (4), respectively. Structure 3·2EtOH was isolated as purple prisms of suitable quality to perform single crystal X-ray diffraction. The structure is comprised of distorted octahedrally coordinated  $\text{Co}^{2+}$  ions bound in a monodentate fashion to two carboxylate functions, two pyridinyl nitrogen atoms and a chelating nitrate molecule (Fig. 3, top).

Each carboxylate function forms a di-monodentate bridging coordination mode between two

crystallographically equivalent  $\text{Co}^{2+}$  ions and, unlike the examples previously reported by Wang and co-workers,<sup>10</sup> this metal-carboxylate binding motif is observed at both carboxylate functions of the 5-AIP linker, with  $180^\circ$  rotation of successive 5-AIP units giving extended 1-D chains. These chains are linked to their four nearest neighbours through the coordination of 4,4'-bipyridyl units which are approximately parallel to the *a* axis, but in two different, mutually angled, orientations, giving a herringbone motif and linking the chains into a 3-D structure (Fig. 3, bottom). Chelated nitrate molecules lie out of plane of the 5-AIP units, extending into one dimensional channels with dimensions of  $7.08 \times 4.18 \text{ \AA}$  observed parallel to the *b* axis, with each nitrate unit forming a hydrogen bond to guest ethanol molecules (Fig. 3, bottom, right).

Structure 4·2DMF was also synthesised as purple prisms. However, due to severe and, not fully resolved, twinning problems, the single crystal X-ray diffraction data collected was sufficient only to establish connectivity. The space group for 4·3DMF seems to be  $P2_1/c$  with unit cell: *a* =

Fig. 9 Top: The metal coordination environment in  $[\text{Mn}(5\text{-AIP})(4,4'\text{-azopy})] \cdot 8 \cdot 2.5\text{DMF}$ . Bottom: Diagram of the extended structure of  $8 \cdot 2.5\text{DMF}$  (parallel to the  $b$  (left) and  $c$  (right) axes).

13.726(13),  $b = 16.881(14)$ ,  $c = 14.234(13)$ ,  $\beta = 104.396(19)$  which is consistent with the (pseudo)-isomorphic 5-2DMF, 7-6DMA, and 8-2.5DMF. Similarities observed in the powder X-ray patterns collected for this structure and the related 7 (see below) supported the view that they are isostructural and that the synthesis of the 3-D framework  $\{[\text{Co}(5\text{-AIP})(\text{DPE})] \cdot 2\text{DMF}\}_n$  had been successful. This assertion is also supported by the similarities between the TGA data collected for this and the related structures and by elemental analysis. The structure of 4-2DMF is comprised of 6-coordinate, distorted octahedral  $\text{Co}^{2+}$  nodes coordinated to a single chelating carboxylate group, two monodentate carboxylate oxygens from different molecules, and two pyridinyl nitrogen atoms (Fig. 4, top).

The 2-D sheets generated by the interaction of the 5-AIP linker with the  $\text{Co}^{2+}$  nodes exhibiting the 32 membered macrometalloacycles, located in the  $b/c$  plane, are the metal-carboxylate binding mechanism observed in this sample.

Additionally, the proximity of N to O (2.83 Å) clearly indicates the presence of hydrogen bonding supporting the covalent bonding in this plane. Pillaring DPE linkers extend in the  $a$  direction, giving the 3-D structure (Fig. 4, bottom). It is of particular note that the larger void spaces resulting from the use of a longer dipyrindyl linker allows the inclusion of larger guest molecules than in 3, with two disordered DMF molecules per formula unit inhabiting intersecting 1-D channels observed parallel to the  $b$  and  $c$  axes.

Reaction of  $\text{H}_2\text{-5-AIP}$  with cobalt nitrate hexahydrate in the presence of 4,4'-azopy in a DMA/EtOH mixture afforded 5-2DMA as dark red prisms of suitable quality for structural elucidation by single crystal X-ray diffraction. This reveals a 3-D MOF of the formula  $\{[\text{Co}(5\text{-AIP})(4,4'\text{-azopy})] \cdot 2\text{DMA}\}_n$  which is isostructural with 4-2DMF, bearing the same carboxylate binding motif, with both groups adopting bidentate coordination modes, one chelating to a single

**Fig. 10** Top: Diagram of  $\{[\text{Cd}(5\text{-AIP})(4,4'\text{-bipy})]\cdot 3\text{DMF}\}_n$ , 9-3DMF, showing the coordination environment around the  $\text{Cd}^{2+}$  nodes. Bottom: Diagram of 9-3DMF showing the extended structure as viewed along the  $a$  axis (left) and  $b$  axis (right). Carbon, nitrogen, oxygen, hydrogen, and cadmium atoms are coloured brown, blue, red, pink, and dark pink, respectively.

cobalt centre and the other exhibiting bridging behaviour between two metal nodes (Fig. 5). As with 4-2DMF, the proximity of the amine nitrogen N(5) to the carboxylate oxygens O(2A) and O(4B) clearly indicates the presence of hydrogen bonding interactions within the Co(5-AIP) sheets.

Coordination of the 4,4'-azopy linker above and below the plane of the Co(5-AIP) sheets gives the extended 3-D structure which bears intersecting channels of  $7.47 \times 9.80 \text{ \AA}$  and  $3.38 \times 9.80 \text{ \AA}$  observed parallel to the  $b$  and  $c$  axes respectively (Fig. 6). In the as-synthesised MOF, these channels contain highly disordered DMA molecules. These could not be refined using point atom observations, hence the PLATON squeeze procedure was performed, recovering 399 electrons per unit cell. This equates to 8 DMA molecules per unit cell, or 2 per formula unit.

### Manganese complexes

Solvothermal reaction of  $\text{H}_2\text{-5-AIP}$  with 4,4'-bipyridyl and  $\text{Mn}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  in a DMA/ethanol mixture afforded yellow prisms of suitable quality for single crystal X-ray diffraction. Structural elucidation revealed an extended 3-D framework of the formula  $\{[\text{Mn}(5\text{-AIP})(4,4'\text{-bipy})]\cdot 2\text{DMA}\}_n$  (6-2DMA), which

is isomorphous to the previously described  $\{[\text{Co}(5\text{-AIP})(\text{DPE})]\cdot 3\text{DMF}\}_n$  (4-2DMF) and  $\{[\text{Co}(5\text{-AIP})(4,4'\text{-azopy})]\cdot 2\text{DMA}\}_n$  (5-2DMA) structures (Fig. 7, top).

In this example, the 5-AIP unit links  $\text{Mn}^{2+}$  ions in the  $ab$  plane, with 4,4'-bipyridyl units linking these sheets in the  $c$  direction. Atoms N(2), C(6), C(7), and C(11) were modelled as disordered across the mirror in the  $ab$  plane (Fig. 6, right). As with 4-2DMF, the proximity of the N(2) atom to O(1') ( $2.91 \text{ \AA}$ ) clearly indicates the presence of a hydrogen bonding interaction. Disordered DMA molecules were modelled using the PLATON squeeze procedure which recovered 410 electrons in one large void per unit cell. Given the point atom observations, 8 DMA molecules per unit cell, or two per formula unit, were considered reasonable, located in intersecting channels of  $2.67 \times 8.21$  and  $1.38 \times 8.21 \text{ \AA}$  observed along the  $a$  and  $b$  axes respectively (Fig. 7, bottom).

The solvothermal reaction of  $\text{H}_2\text{-5-AIP}$  with DPE and  $\text{Mn}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  also afforded yellow prisms of suitable quality for single crystal X-ray diffraction. Structure 7-6DMF is isostructural with 4-2DMF, 5-2DMA, and 6-2DMA with 2-D sheets of Mn(5-AIP) observed in the  $b/c$  plane being linked *via* the dipyrindyl unit, giving the structural formula  $\{[\text{Mn}(5\text{-AIP})(\text{DPE})]\cdot 6\text{DMF}\}_n$  (Fig. 8, top).

Fig. 11 Top: Diagram of 10-4.5DMF showing the coordination environment around the  $\text{Cd}^{2+}$  nodes. Bottom: Diagram of 10-4.5DMF showing the extended structure as viewed along the  $b$  axis (left) and  $c$  axis (right). Carbon, nitrogen, oxygen, hydrogen, and cadmium atoms are coloured brown, blue, red, pink, and dark pink, respectively.

As with 4-2DMF, the use of a longer dipyriddy linker gives rise to the elongation of the pores in the  $a$  direction, giving intersecting one dimensional channels of  $10.98 \times 5.84$  and  $10.98 \times 3.51$  Å. As in 4-2DMF, this leads to the incorporation of a greater quantity of guest solvent molecules. A total of six DMF molecules are observed per formula unit. The first of these is well defined, due to the hydrogen bonding interaction of the aldehydic oxygen with the ethylene linkage of the dipyriddy unit and is refined as point atoms; however, the remaining five are disordered and are modelled using the PLATON squeeze procedure as diffuse areas of electron density. As with the other isostructural frameworks, the intersecting 1-D channels containing these guest DMF molecules are visible along the  $b$  and  $c$  axes (Fig. 8, bottom).

Reaction of  $\text{H}_2$ -5-AIP and 4,4'-azopy with  $\text{Mn}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  under solvothermal conditions also afforded a crystalline solid in good yield. Elemental analyses conducted on samples of the crystals which had been dried by heating to  $120$  °C under dynamic vacuum for 12 h gave the formula  $[\text{Mn}(\text{5-AIP})(4,4'\text{-azopy})]$ , with the powder X-ray pattern collected for 8,

mirroring the pattern simulated for the cobalt analogue of this structure, 5-2DMA, with similar line spacing and intensities observed for both structures. A single crystal X-ray diffraction study revealed a sheet structure in the  $b/c$  plane, with the azo ligands forming pillars between these sheets. One carboxylate group bridges pairs of  $\text{Mn}^{2+}$  ions, while the other chelates to the metal ion. The sheets are slightly undulating. The sheets are further stabilised by hydrogen bonds from the  $\text{NH}_2$  group to carboxylate oxygens at 3.18 and 2.95 Å. The DMF solvent of crystallisation lies between the pillars (Fig. 9).

There is some evidence of slight rocking disorder in the azo pillaring ligand, but this was not modelled as it was not too severe. Point atom analysis suggested 2–3 DMFs, all diffuse and disordered and these were modelled as a diffuse area of electron density by the PLATON squeeze procedure. Squeeze recovered 379 electrons per unit cell. DMF has 40 electrons, so there are approximately 10 DMFs per unit cell, or 2.5 per formula unit, *i.e.*  $[\text{Mn}(\text{5-AIP})(4,4'\text{-azopy})] \cdot 2.5\text{DMF}$ .

Fig. 12 Top: Diagram of  $\{Cd(5-AIP)(4,4'-azopy)(DMF)\}_n$ , **11**, showing the coordination environment around the metal nodes. Bottom: Diagram of the extended structure of **11** as viewed along the *a* axis (left) and *b* axis (right). Coordinated DMF molecules are visible between the 4,4'-azopy units. Carbon, nitrogen, oxygen, hydrogen, and cadmium atoms are coloured brown, blue, red, pink, and dark pink, respectively.

### Cadmium complexes

Reaction of  $Cd(NO_3)_2 \cdot 4H_2O$ ,  $H_2$ -5-AIP and 4,4'-bipy in DMF/methanol afforded colourless prisms of **9**·3DMF. The extended structure of **9**·3DMF is formed by the coordination of 4,4'-bipy units in the apical positions of the metal nodes.

These neutral linkers, observed parallel to the *c* axis, link 2-D  $[Cd(5-AIP)]_n$  sheets into an extended 3-D framework exhibiting intersecting 1-D pores of  $3.21 \times 8.30$  and  $3.96 \times 8.30$  Å (Fig. 10). Badly disordered guest molecules situated inside these pores could not be resolved satisfactorily, however the PLATON squeeze procedure recovered 488 electrons situated in one void

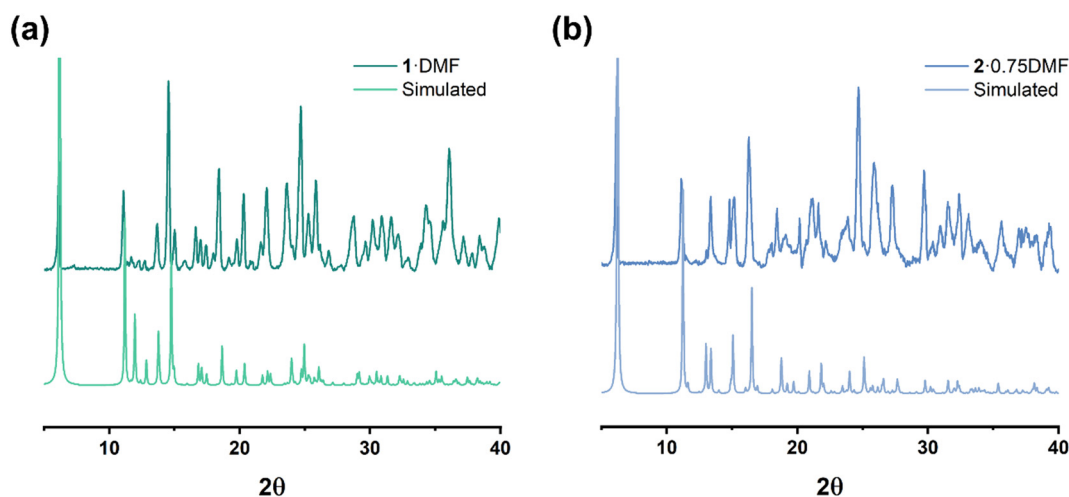

Fig. 13 Powder X-ray diffraction of (a) 1·DMF; (b) 2·0.75DMF.

Fig. 14 Infrared radiation spectra of all complexes.

Fig. 15 SEM patterns for (a) 1-DMF; (b) 2-0.75DMF; (c) 3-2EtOH; (d) 4-2DMF; (e) 5-2DMA; (f) 6-2DMA; (g) 7-6DMF; (h) 8-2.5DMF; (i) 9-3DMF; (j) 10-4.5DMF; (k) 11.

per unit cell, situated around the 4,4'-bipy linkers. This data, in conjunction with point atom observations, led to the conclusion that twelve DMF molecules per unit cell, or three per formula unit are present in the as-synthesised framework.

The same reaction conditions as in the preparation of 7-6DMF but using cadmium nitrate tetrahydrate led to the isolation of colourless prisms of 10-4.5DMF. Single crystal X-ray diffraction of 10-4.5DMF revealed a related framework to the five described previously. However, minor differences are observed in the coordination modes of the carboxylate groups. In this example, the larger coordination sphere of  $\text{Cd}^{2+}$  allows the chelation of carboxylate moieties from two different 5-AIP units to each metal node, with one oxygen atom of each of these units bridging to a second  $\text{Cd}^{2+}$  centre. In this manner each metal centre bonds to three 5-AIP units in the *a/b* plane, with pyridinyl nitrogens bound in the apical positions giving hepta-coordinate metal centres exhibiting distorted pentagonal bipyramidal geometry (Fig. 11). The hydrogen atoms associated with each  $\text{NH}_2$  group were modelled in geometrically determined positions, and it is clear that these groups are involved in hydrogen bonding with the oxygen atoms of the neighbouring 5-AIP units due to the proximity to the  $\text{NH}_2$  group at 2.933(7) and 2.988(7) Å.

Solvothermal reaction of  $\text{H}_2$ -5-AIP and 4,4'-azopyridine with  $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  afforded 11 as red prisms, which were of suitable quality for single crystal X-ray diffraction. Elucidation of the structure revealed very different topology to the frameworks detailed previously. In this example, each  $\text{Cd}^{2+}$  node has a pentagonal bipyramidal geometry, coordinating to two chelating carboxylate groups from different molecules and a pyridinyl nitrogen in the pentagonal plane, and to a DMF molecule and an amine nitrogen in the axial plane (Fig. 12, top).

Covalent bonding propagates in the *a/c* plane, forming bilayer sheets of  $\text{Cd}(5\text{-AIP})$  linked *via* the coordinate bonding of the dipyrindyl. As with the 3-D hybrid covalent/H-bonded frameworks 1 and 2, significant hydrogen bonding interactions between the bilayer sheets, in this example between the  $\text{NH}_2$  groups and two carboxylate oxygens, link them into the extended 3-D structure (Fig. 12, bottom). However, unlike the previous examples, there are no large voids filled with disordered solvent. Only one DMF molecule per formula unit is observed in this structure, located in the intersecting 1-D channels of dimensions  $3.89 \times 6.54$  and  $3.77 \times 7.18$  Å extending in the *a* and *b* axes, respectively, and acting as a ligand coordinated to the  $\text{Cd}^{2+}$  centre *via* the aldehyde oxygen.

<sup>a</sup> [M] represents the concentration per metal (M = Zn, Co, Mn, Cd). <sup>b</sup> Conversion was confirmed by <sup>1</sup>H NMR spectroscopy. <sup>c</sup> GPC analysis in THF at ambient temperature and polystyrene standards were used to calibrate the results (corrected by a factor of 0.56). <sup>d</sup> Polydispersity index ( $M_w/M_n$ ) were calculated by GPC. <sup>e</sup> Time = 12 h.

### PXRD results

A comparison of simulated and experimental PXRD data for complexes 1–2 is provided in Fig. 13 (3–11 are provided in Fig. S1†). Although the intensity of the peak varies, the majority of the observed results are in accord with their simulated patterns.

### IR results

To further investigate the chemical bonding, infrared spectroscopy was performed (Fig. 14). Without the use of a solvent, all complexes were studied at ambient temperature. The bands between 3000 and 3350 cm<sup>-1</sup> are ascribed to aromatic C–H stretching vibrations, whilst peaks near 1600 and 1500 cm<sup>-1</sup> are attributed to the C=O groups. C–N stretching vibrations of the aromatic amine cause sharp peaks around 1300 cm<sup>-1</sup>. These IR results are consistent with the above structural analyses.

### SEM results

Under an electron microscope, all of the complexes have various intriguing structures (Fig. 15). Different degrees of

agglomeration occur for all complexes, with most exhibiting regular structures. The structures of 1·DMF, 3·2EtOH, and 9·3DMF are chunk-like, whereas the structure of 2·0.75DMF is crisp. MOF 4·2DMF is particle shaped. MOFs 5·2DMA and 10·4.5DMF are rod-like. MOFs 6·2DMA and 7·6DMF exhibit larger, more pronounced, rod-like structures, whilst 8·2.5DMF appears to adopt large, block-like clumps. Lozenge-shaped blocks are adopted by 11. Fig. S3† displays the mapping scanning of 1·DMF, which reveals that the metal is evenly dispersed throughout the complex.

### Ring opening polymerization (ROP) studies

The MOFs herein were screened for their ability to act as catalysts for ring opening polymerization (ROP) of

<sup>a</sup> All conducted with different ratios [M]:[monomer] in 1:500, [M] in the ratio means each mol element (Zn, Co, Mn, Cd). <sup>b</sup> Conversion was confirmed by <sup>1</sup>H NMR spectroscopy. <sup>c</sup> GPC analysis in THF at ambient temperature and polystyrene standards were used to calibrate the results (corrected by a factor of 0.58). <sup>d</sup> Polydispersity index ( $M_w/M_n$ ) were calculated by GPC.

$\epsilon$ -caprolactone ( $\epsilon$ -CL) and  $\delta$ -valerolactone ( $\delta$ -VL). The MOFs were activated by soaking with chloroform solution for 12 h, and then removing the solution and subsequently drying in a vacuum oven to remove remaining solvent. The activated MOFs are referred to below as catalysts 1–11. Using catalyst 1, the experimental conditions including temperature, solvent, atmosphere (N<sub>2</sub> or air), and the ratio of [M]:[monomer] were optimized. When the ROP was conducted in solvent (normally toluene), all catalysts were inactive. A possible reason is that the solvent molecules occupy the channels in these MOFs and hamper monomer access to the metal sites. Therefore, all MOFs must be activated prior to the ROP procedure and then reacted with the monomer as a melt. Taking catalyst 1 as an example, the optimum conditions were found to be [M]:[monomer] = 1:500 at 130 °C over 24 h under air (Table 1, entry 1–7). Note, all catalysts were inactive under nitrogen except for catalyst 1 with  $\delta$ -VL. Table 1 shows the polymerization with  $\epsilon$ -CL under air. Catalysts 1, 2, 6,

**Fig. 19** MALDI-TOF mass spectrum of PVL (Table 2, entry 1).

and 11 revealed activity, with 1, 2, and 11 exhibiting high conversions of >90%. For the system employing catalyst 1, the afforded polycaprolactone (PCL) possessed the highest molecular weight ( $M_n = 7170$  Da), whilst the narrowest molecular weight distribution (PDI = 1.66) was produced using catalyst 2. From the <sup>1</sup>H NMR spectra (Fig. 16) of PCL, it was evident that both cyclic and linear polycaprolactone were formed. Similar results were obtained using the other catalysts (Fig. S5–S7, ESI†). The MALDI-TOF mass spectrum of the PCL afforded using catalyst 1 (Table 1, entry 3) is shown in Fig. 17, and peaks can be observed at  $m/z$  6919.963 ( $n = 60$ ), 7029.731 ( $n = 61$ ), 7138.872 ( $n = 63$ ), etc., which correspond to cyclic PCL with Na<sup>+</sup> ( $m/z$ :  $114.14 \times n + 22.99$ ). A minor family of peaks corresponds to linear PCL of formula (OH(CL)<sub>n</sub>H) with Na<sup>+</sup> ( $m/z$ :  $18.00 + 114.14 \times n + 22.99$ ). Similar results can be found for the MALDI-TOF mass spectra of the PCL catalyzed using catalysts 2, 6, and 11 (Fig. S8–S10, ESI†).

Better results were exhibited for the ROP of  $\delta$ -VL. All catalysts were active under air, and catalyst 1 was also active under nitrogen. In most cases (except 8), ~90% or more conversion was achieved, with high molecular weights ( $M_n = 8200$ , Table 2, entry 2) and narrow molecular weight distribution (e.g. PDI = 1.31, Table 2, entry 7). End group analysis by <sup>1</sup>H NMR spectroscopy revealed similar results to PCL, whereby cyclic PVL (Fig. 18), and other minor PVL families were observed (Fig. S11–S21†). The MALDI-TOF mass spectrum of the PVL obtained using catalyst 1 (Table 2, entry 1) is shown in Fig. 19, and signal peaks can be observed at  $m/z$  6962.644 ( $n = 69$ ), 7058.687 ( $n = 70$ ), 7154.559 ( $n = 71$ ), etc. corresponding to cyclic PVL with Na<sup>+</sup> ( $m/z$ :  $100.12 \times n +$

**Fig. 18** <sup>1</sup>H NMR spectrum of PVL (Table 2, entry 1).

Fig. 20 (a) Powder X-ray diffraction and (b) infrared radiation spectra of catalyst 1 before and after 1st recycle.

22.99). Minor peaks correspond to linear PVL of formula  $(\text{OH}(\text{VL})_n\text{H}$  or  $\text{H}_3\text{CO}(\text{VL})_n\text{H}$ ) with  $\text{Na}^+$  ( $m/z$ : 18.00 or 32.03 +  $100.12 \times n + 22.99$ ). Similar results can be found in the MALDI-TOF mass spectra of PVL catalyzed by 1 under nitrogen and catalysts 2–11 under air (Fig. S23–S33†).

### Recyclability studies

Catalyst 1 was employed for the recyclability studies. The catalyst was retrieved from the polymers by washing with dichloromethane using the method reported by Verpoort *et al.*<sup>23</sup> PXRD and IR spectra (Fig. 20) confirm that the catalyst retains its structural integrity after recycling. Table 3 shows catalyst 1 retains high activity (conversion ~99%), however the PCL product exhibits decreased molecular weight and a wider molecular weight distribution after recycling.

### Kinetics studies

Kinetic studies using catalysts 1, 2, 6, and 11 for the ROP of  $\epsilon$ -CL are shown in Fig. S34.† The slope (“*b*” in the figure) of the linear fit reflects the catalytic rate trend. It is evident that

when catalyst 11 is employed as the catalyst for the ROP of  $\epsilon$ -CL, the slope is greatest, suggesting that catalyst 11 has the largest rate trend, albeit with a significant induction period. Catalyst 1 exhibits comparable rate trends with catalyst 11, while catalyst 6 is the slowest.

According to the slope of the linear plots from the kinetics studies for catalysts 1–11 (Fig. S35†), the rate trend of the ROP with  $\delta$ -VL is  $2 > 5 > 11 > 6 > 4 > 1$  (under air)  $> 3 > 9 > 7 > 10 > 1$  (under nitrogen)  $> 8$ . The results indicate that catalyst 2 is the best system for the ROP of  $\delta$ -VL, given it has the highest rate trend and initiates the ROP without an induction period.

It is evident from the results that several catalysts (3–5, 7–10) are inactive in the ROP of  $\epsilon$ -CL, but active in the ROP of  $\delta$ -VL. Fig. S36† gives the structures of  $\epsilon$ -CL and  $\delta$ -VL monomer. It can be clearly seen that  $\delta$ -VL monomer has a smaller molecular diameter than  $\epsilon$ -CL, which will be beneficial in terms of accessing the active metal sites in the MOFs. However, the trend here for more facile ROP of  $\delta$ -VL versus that of  $\epsilon$ -CL, is in contrast to the thermodynamic parameters for these lactones.<sup>32</sup>

Fig. 21–24 show the repeating cells of catalysts 1–11, the dashed line between the two marked atoms was

Fig. 24 Repeating cells of catalysts (a) 9, (b) 10, and (c) 11.

measured and approximately reflects the inter-pillar distance. It can be observed that those catalysts (3–5, 7–10) that have activities only in ROP with  $\delta$ -VL have inter-pillar distance less than 7.1 Å. In comparison with other catalysts, catalyst 2 has the largest repeating cell inter-pillar distance (Fig. 21(b)). Therefore, catalyst 2 showed excellent performance both in ROP with  $\epsilon$ -CL and  $\delta$ -VL. By comparing the repeating cell inter-pillar distance of catalyst 3 (Fig. 22(a)) and 8 (Fig. 23(c)), despite having a smaller inter-pillar distance than catalyst 8, catalyst 3 exhibited higher conversion (Table 2) and rate trend (Fig. S35<sup>†</sup>). It could be attributed to the differences between the cobalt (catalyst 3) and manganese (catalyst 8) atoms.

## Conclusion

In conclusion, eleven 2- and 3-D MOFs have been synthesised using the solvothermal reaction of 5-aminoisophthalic acid with the nitrates of zinc, cobalt, manganese, and cadmium in the presence of the neutral pillaring linkers 4,4'-bipyridyl, 4,4'-azopyridine, and 1,2-bis(4-pyridyl)ethylene. The MOFs have been structurally characterised, and their ability to act as catalysts for the ROP of  $\epsilon$ -CL and  $\delta$ -VL investigated. Only selected MOFs are active in the ROP of  $\epsilon$ -CL, whereas all exhibit activity in the ROP of  $\delta$ -VL. We tentatively attribute the differences in activity to steric hindrance. By measuring the inter-pillar distance of the repeat units of catalysts 1–11,

it can be concluded that a inter-pillar distance greater than 7.2 Å is favourable for the ROP of ε-CL. Other factors are also at play, and the results suggest that for these 11 catalysts the ROP behaviour is influenced by both the metal ions present and the pore size of the repeat unit. Cyclic and linear PCL and PVL were identified by <sup>1</sup>H NMR spectra and MALDI-TOF mass spectra. A kinetics study revealed the rate trend of the MOFs during catalysis. Catalyst **11**{Cd(5-AIP)(4,4'-azopy)(DMF)}<sub>n</sub> in ROP of ε-CL and catalyst **2**{[Zn(5-AIP)(4,4'-azopy)0.5]-DMF}<sub>n</sub> in ROP of δ-VL performed best. It is interesting to note that catalyst **1**{[Zn(5-AIP)(4,4'-bipy)0.5]-DMF}<sub>n</sub> is active for the ROP of δ-VL whether under nitrogen or air.

## Conflicts of interest

There are no conflicts of interest to declare.

## Acknowledgements
