Polymeric and inorganic sorbents as a green option to recover critical raw materials at trace levels from sea saltwork bitterns†

V. Vallès,^{a,b} J. López,^{a,b} M. Fernández de Labastida,^{a,b} O. Gibert,^{a,b} A. Leskinen,^c R. T. Koivula^d and J. L. Cortina^{a,b,e}

Seawater mining is certainly a green alternative source for obtaining minerals as seawater is a natural renewable and unlimited available resource. Based on the lack of ways to obtain certain raw materials, the European Union has created the Critical Raw Materials (CRM) list. Seawater contains almost all elements, including some of those present in the CRM list, but only a few are economically feasible to be extracted as most of them are considered Trace Elements (TEs) ($\mu\text{g L}^{-1}$). Therefore, an improvement in TEs extraction must be carried out. Saltwork brines can be considered as they are naturally concentrated (20–40 times) compared to seawater, which makes the extraction and recovery of TEs easier. Selective polymeric and inorganic sorbents were evaluated for TEs recovery (Li, B, Co, Ga, Ge, Rb, Sr, and Cs) from synthetic brines mimicking sea saltwork bitterns. Distribution coefficients were determined to characterize selectivity patterns toward TEs. Although amine and sulphonic sorbents showed low sorption of TEs, carboxylic sorbents presented good sorption and recovery for Co and Ga. Among phosphonic/phosphinic sorbents, MTX8010 achieved >98% sorption and desorption of Ga. Aminophosphonic and iminodiacetic are the best sorbents for Sr, but its desorption was incomplete. B was only sorbed by *N*-Methylglucamine (>98%) and *N*-Methylpyridine sorbents (75%), and its desorption was 37–64% and 66–>99%, respectively. SbTreat presented good performance targeting Ga and Ge, and CsTreat demonstrated high Cs uptake, but its desorption was unachieved. The most highly selective sorbents could provide the possibility of building a green option to recover critical elements for societal development in the next decade.

Introduction

The economy of European Union (EU) has a wide industrial sector, which needs raw materials to prosper with their activities. Many of these raw materials are produced in countries outside the EU. This fact makes the EU dependent on international markets to ensure accessibility to these materials. To obtain raw materials on a continuous and secure basis, the EU has begun to implement circular economy policies.

Considering their economic importance (*i.e.*, the value that these materials add to the final products) and their supply risk, taking into account the location of primary sources, the European Commission created a list of Critical Raw Materials (CRMs) in 2011, which nowadays has been reviewed and expanded to include 30 elements.¹ Many of them are metals or minerals, of which the EU has no primary sources. As an example, 98% of rare earth elements used in the EU are provided by China, whereas Turkey supplies 98% of borate minerals. Practically, the EU itself has reserves of only two of the CRMs, hafnium and strontium.² Therefore, due to the fact that most CRMs are needed not only in process industries but also in technological sectors (*e.g.*, communication, energy, and mobility), the EU is looking for secondary sources of these CRMs from the recovery and valorization of waste. One of the alternative sources is seawater mining.³

Seawater, with a 3.3% (w/w) content of dissolved salts, contains almost all the elements from the periodic table, although most of them are at very low concentration levels.^{4,5} This makes seawater a potential alternative source for most CRMs.⁶ In fact, humanity has been extracting minerals from seas and oceans since ancient times; the most evident example is the common

table salt NaCl. However, only the elements at higher concentration (major elements, *i.e.*, Na, Mg, Ca, and K) are extracted from seawater with commercial purposes.⁷ Nevertheless, seawater extraction may represent an alternative source for minor elements considered as CRMs (*e.g.*, Li, Co, or rare earth elements), without producing any damaging impact on marine ecosystems.⁸ Moreover, seawater presents the advantage of being homogeneous, which, in contrast to land mining, leads to the scenario in which there is no mineral grade difference.⁴

Although the concept of extracting minerals from seawater could be possible, the extremely low concentrations of some of the elements (*i.e.*, Trace Elements (TEs); at $\mu\text{g L}^{-1}$ levels or less) would make the process extremely complex and economically unviable. Therefore, the use of seawater brines, such as those from membrane-based desalination plants, with salt concentrations higher compared to seawater (*ca.*, 6.6% (w/w)) would favour the recovery of these metals or minerals.⁹ Another kind of seawater brine can be found in seawater solar saltworks, which are defined as a group of shallow ponds where the concentration of saline water and sodium chloride crystallization take place.¹⁰ In comparison to the desalination plants, their operation is based on solar energy, although most of them are constructed in such a way that they can also take advantage of the wind for evaporating the water.^{11,12} Even though their efficiency depends on their location and environmental conditions, all of them are constructed with a similar structure: supply, evaporation, and crystallization ponds.¹² Firstly, seawater enters the supply ponds, which are the biggest and deepest ponds of the saltworks. Then, water flows into evaporation ponds, a group of basins covering 90% of the saltworks' area.¹³ In these ponds, water is evaporated thanks to the sun radiation and the wind until NaCl concentration approaches its saturation point. Finally, the water enters into crystallization ponds, where NaCl achieves its solubility limit, precipitates, and accumulates at the bottom of the ponds.¹² Along these long-term evaporation stages (*e.g.*, typically one year), many minerals precipitate along the ponds, causing a fractionated precipitation of different inorganic Ca(II) salts. First, carbonates (mainly $\text{CaCO}_3(\text{s})$) precipitate when water reaches a total salt concentration of about 100–120 g L^{-1} . Then, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}(\text{s})$ precipitates when total dissolved salt concentration is about 180 g L^{-1} . Finally, NaCl precipitates after reaching concentrations of 300–350 g L^{-1} . This type of fractionated precipitation makes it possible to obtain a salt with a low content of impurities (<0.3% (w/w)).¹¹ The remaining concentrated liquid is commonly called bittern, and it has high amounts of Mg(II), K(I), Cl(–), and S(VI).^{14,15} Although this bittern is up to 40 times more concentrated than seawater, some CRMs that could be recovered are still at trace level concentrations ($\mu\text{g L}^{-1}$ or ng L^{-1}). Therefore, it is necessary to make efforts for improving the extraction procedures to achieve economic feasibility.¹⁶

Several processes can be used for mining these bitterns and recovering valuable minerals. These processes can be classified, for example, depending on the type of driving force used: pressure-driven (*e.g.*, reverse osmosis), thermally driven (*e.g.*, evaporation), electrochemical potential-driven (*e.g.*, electrodialy-

sis), and physico-chemically driven (*e.g.*, sorption and ion exchange).^{9,17} In fact, although not many studies have been reported regarding the recovery of TE from seawater or brines, the literature indicates sorption and ion exchange processes as the most suitable methods for the recovery of most of them (*e.g.*, Li, Sr, Rb, and Cs) because of the high selectivity of the sorbents, which appears as an essential property when dealing with elements at trace levels ($\mu\text{g L}^{-1}$ or ng L^{-1}).^{4,9,18,19} In addition, sorption processes are not only selective but also simple, efficient, and low-cost methods to extract these TE.^{4,17,20}

Scarce works can be found in the literature regarding the extraction of valuable elements at low concentrations from brines. Arroyo *et al.* (2019),²¹ for example, evaluated three polymeric commercial ion exchange sorbents (K2629 – sulphonic sorbent – and TP207 and TP208 – both of them iminodiacetic sorbents) targeting Li recovery in brines. For solutions (50 mL) containing only 10 mg L^{-1} Li, they reported that more than 95% of Li was removed from the solution in 20 minutes using only 1 g of the sorbent. In addition, after achieving over 98% sorption, an elution test was performed with 50 mL HCl (3 or 4 M). When 3 M HCl was used, the desorption percentages of Li were between 74% and 87%, whereas using 4 M HCl these values increased and ranged between 80% and 90%. After the elution, the authors conditioned again the sorbents to the H^+ and Na^+ form and reused them for further Li extraction. On the other hand, in their Na^+ form, Li removal remained at about 98%, and in their H^+ form, removals using TP207 and TP208 decreased to 52% and 40%, respectively (for K2629 removal, it was still about 98%). Despite the high Li sorption achieved with synthetic solutions, when real Seawater Reverse Osmosis (SWRO) brines (15.3 g L^{-1} Na^+ , 28.7 g L^{-1} Cl^- , 4.60 g L^{-1} SO_4^{2-} , and 0.60 mg L^{-1} Li^+) were tested, Li retention was in the range of 30–80% depending on the type and amount (10 or 20 g) of sorbent. Nur *et al.* (2017)²² synthesized a Resorcinol Formaldehyde (RF) sorbent and compared its performance with commercial ones (*i.e.*, CsTreat, Ammonium MolybdoPhosphate (AMP), a natural zeolite, and Amberlite FPC 3500) targeting Sr removal. Among all sorbents tested for a solution containing only 10 mg L^{-1} Sr, the Na^+ form of RF achieved the highest Sr removal (>95%) for doses of 1 g L^{-1} sorbent or higher. However, when synthetic seawater (20 g L^{-1} Na, 2 g L^{-1} Mg, 1 g L^{-1} Ca, 0.85 g L^{-1} K, and 0.01 g L^{-1} Sr) was tested, Sr sorption decreased to 40% due to competition between Ca and Mg ions. Desorption tests with 100 mL NaCl or NaOH (1 and 2 M) were performed for 1 g saturated RF, but Sr recoveries over 90% were only possible using NaCl. RF sorbent was also tested in column experiments with three inlet solutions with 10 mg L^{-1} Sr but differing in that one contained only Sr in water, a second one Sr in the seawater medium, and the third one Sr in the seawater medium but without Ca and Mg. Sr adsorption capacities were 22, 6, and 11 mg g^{-1} for the three solutions described, indicating that seawater medium influence the Sr adsorption and that part of this influence is caused by the presence of Ca and Mg. Gibert *et al.* (2010)²³ performed column experiments to retain Rb and Cs with CsTreat sorbent ($\text{K}_2\text{CoFe}(\text{CN})_6$) using a SWRO brine containing mainly 70.0 g L^{-1} NaCl, 6.4 g L^{-1} SO_4^{2-} , and

2.5 g L⁻¹ Mg²⁺, with other ions (*i.e.*, CO₃²⁻, K⁺, and Ca²⁺) in the range from 130 to 669 mg L⁻¹ and a few elements (*i.e.*, Rb⁺ and Cs⁺) spiked to 20 mg L⁻¹. They reported sorption capacities of 44 mg g⁻¹ for Cs and 238 mg g⁻¹ for Rb. Using the same sorbent and brine but enriching its Rb and Cs concentrations to range 5–80 mg L⁻¹, Peterková *et al.* (2012)²⁴ reported Langmuir maximum sorption capacities (Q_{\max}) of 32 mg g⁻¹ for Cs and 47 mg g⁻¹ for Rb. Also regarding Rb sorption in the batch mode, Naidu *et al.* (2016)²⁵ synthesized other hexacyanoferrate compounds and reported that KCuFC had the highest Rb sorption (Q_{\max} = 144 mg g⁻¹) as Q_{\max} values for KNiFC, KCoFC, and KFeFC were under 122 mg g⁻¹. Authors encapsulated KCuFC in PolyAcryloNitrile (PAN), which resulted in a new sorbent (KCuFC-PAN) with a slight lower Q_{\max} value of 105 mg g⁻¹. Under high salinity (0.2–2.5 M NaCl, simulating SWRO brine), the sorption capacity was reduced by only 12–30%, although the presence of K led to a reduction of 65–70%. A Rb sorption capacity of 86.32 mg g⁻¹ was then reported for KCuFC-PAN when they operated it in the column mode, which was also able to desorb it by a 95% using 0.2 M KCl. After desorption, the sorption capacity was reduced by only 16% in a second cycle of sorption/desorption. These works revealed that it is possible to recover valuable elements at relatively low concentration values from seawater brines.

Within this context, several research projects aim to recover CRMs and other valuable elements (Sc, V, Mo, and In, among others) from seawater or brines,^{26,27} specifically targeting the recovery of Mg, Li, and some TEs (*i.e.*, B, Co, Ga, Ge, Rb, Sr, and Cs) from saltworks bitters. ²⁸ Moreover, considering their initial estimations, about 10⁷ m³ per year of bitters are produced in the Mediterranean area. Therefore, several TEs could be recovered from them, including about 360 tn per year (tn per year) Li, 2300 tn per year B, 0.43 tn per year Co, 0.47 tn per year Ga, 1.18 tn per year Ge, 75 tn per year Rb, 285 tn per year Sr, and 1.6 tn per year Cs. To demonstrate the potential of recovering these TEs from bitters, 20 Mediterranean saltworks collaborate with this initiative. In addition, according to Sadoul *et al.* (1998),²⁹ 168 saltworks could be found in 18 countries around the Mediterranean basin.

The novel idea of reusing and recycling resources should be highlighted as it must be taken into account that bitters are the “waste” stream produced in saltworks that, in most cases, is returned to the sea. Therefore, a green sustainable circular process (see Fig. 1) has been designed by the EU to transform the bitters into a valuable source of CRMs (from “waste” to raw materials). In addition, advantage is taken of the bitters as salty streams and, by causing a gradient of salinity, part of the electricity required to operate the different technologies included in this proposal is produced using Reverse Electrodialysis.³⁰ Electrodialysis with bipolar membranes is also used to generate the reagents needed along the whole process. In this way, some of the principles of green engineering³¹ were accomplished as, apart from reusing the bitters as a new source to obtain CRMs, the waste generated along this circular scheme is minimized and reused, as well as to obtain energy. Various aspects also allow this initiative to achieve

Fig. 1 Green sustainable circular process for transforming bitters rejected streams into alternative sources to recover CRMs (adapted scheme).³⁴

some of the principles of green chemistry.^{32,33} For example, the fact that at the end of the process, the bitters remaining is at neutral pH and is used to produce energy allow to achieve principles 1 (prevent waste) and 6 (energy efficiency). In addition, as non-hazardous sorbents and membranes are principally used in the different technologies of this proposal, principle 5 (safer solvents and auxiliaries) is also obtained. Finally, considering that the main raw material of the whole process is the bitters produced by the solar evaporation of seawater, that could be considered an unlimited resource available for anyone, principle 7 (renewable feedstocks) is attained.

This paper compares the behavior of 30 commercial sorbents for the recovery of TEs (Li, B, Co, Ga, Ge, Rb, Sr, and Cs) from saltworks bitters using sorption processes. The sorbents tested were either polymeric (containing, *e.g.*, amine, carboxylic, sulphonic, and phosphinic groups) or inorganic (*e.g.*, metal oxides and hexacyanoferrates). The screening of sorbents was performed by testing three different bitters compositions to ascertain the competition between the targeted valuable TEs and the major elements in solution for the sorption sites. In addition, potential sorption mechanisms are suggested for the main retained TEs. Subsequently, desorption was carried out using 0.1 M and 1 M acids (*e.g.*, HCl and H₂SO₄) and bases (*e.g.*, NaOH and NH₃). Finally, a characterization of the best sorbents was performed in terms of distribution coefficients.

Materials and methods

Testing of the sorbents for the take-up and release of CRMs was divided into two groups: polymeric and inorganic sorbents. Due to their different nature both in physical and chemical properties, and more importantly in their level of selectivity, the division is kept also in the text presenting their properties and results.

Table 1 Main properties of the commercial polymeric sorbents evaluated

Functional group	Sorbent (abbreviation)	Supplier	Ionic form	Capacity (eq L ⁻¹)	Humidity content (%)	Particle size (mm)	Density (g L ⁻¹)	Ref.

Sorbents and chemicals

Different polymeric and inorganic commercial sorbents were selected for targeting the TEs present in the bitters. Polymeric sorbents evaluated are collected in Table 1 and classified according to their functional groups.

Table 2 presents the inorganic sorbents evaluated. In addition, their main properties (e.g., supplier, ionic form, capacity, humidity content, particle size, and density) are also shown.

Screening was performed with synthetic solutions and all chemicals used were at least of analytical grade. The following ones were used for the testing of polymeric sorbents: NaCl (PanReac), KCl (PanReac), $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ (Alfa Aesar), $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ (PanReac), NaBr (PanReac), Na_2SO_4 anhydrous (Glentham), LiCl (PanReac), H_3BO_3 (PanReac), Rb_2CO_3 (Sigma-Aldrich), $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ (Alfa Aesar), gallium plasma standard solution Specpure® 10 000 $\mu\text{g mL}^{-1}$ (Alfa Aesar), germanium plasma standard solution Specpure® 10 000 $\mu\text{g mL}^{-1}$ (Alfa Aesar), CsCl (Glentham), NaOH (PanReac), 37% HCl (PanReac), and 69% HNO_3 (PanReac). The following chemicals were used for the preparation of bitters for the testing of inorganic sorbents: NaCl (Merck), KCl (Merck), $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ (Merck), $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ (Merck), NaBr (VWR), Na_2SO_4 anhydrous (Supelco), LiCl (Merck), H_3BO_3 (VWR), RbCl (Merck), $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ (Merck), gallium plasma standard solution 10 000 $\mu\text{g mL}^{-1}$ (J. T. Baker), germanium standard for AAS 1005 mg mL^{-1} (Sigma-Aldrich), CsCl (Merck), and $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$ (J. T. Baker). Desorption solutions for the testing of inorganic resins were at least of analytical grade and prepared from NaOH (J. T. Baker) and 95–97% H_2SO_4 (Merck).

Experimental design

Three different synthetic bitters were prepared to test the sorbents in different conditions, which are expected to take place at the TEs recovery unit. The exiting bitter from the crystallization ponds undergoes a pretreatment process, where most of Li, Ca, and Mg is removed before entering the TEs recovery unit. Consequently, the variability proposed accounts for the different removal or recovery ratios achieved in that pretreatment.

Table 3 Composition of synthetic bitters evaluated during the screening of commercial sorbents

	Bittern 1 With Ca and Mg	Bittern 2 Without Ca and Mg	Bittern 3 Low concentration
pH	7.00 \pm 0.02	7.00 \pm 0.02	7.00 \pm 0.02
g L^{-1}	Na(i) 71.64 \pm 0.76	72.16 \pm 0.10	38.63 \pm 0.29
	K(i) 8.07 \pm 0.07	8.07 \pm 0.02	5.10 \pm 0.04
	Mg(ii) 0.39 \pm 0.03	<0.01	<0.01
	Ca(ii) 0.10 \pm 0.00	<0.01	<0.01
	Cl(–i) 68.22 \pm 0.71	66.58 \pm 0.11	36.26 \pm 0.42
mg L^{-1}	Br(–i) 1.67 \pm 0.02	1.65 \pm 0.01	0.85 \pm 0.01
	S(vi) 63.28 \pm 0.83	63.11 \pm 0.02	29.75 \pm 0.87
	Li(i) 0.32 \pm 0.01	0.19 \pm 0.01	0.80 \pm 0.01
	B(iii) 110.35 \pm 0.83	113.88 \pm 1.56	124.50 \pm 0.88
	Rb(i) 3.49 \pm 0.02	2.26 \pm 0.02	10.28 \pm 0.03
$\mu\text{g L}^{-1}$	Sr(ii) 10.77 \pm 0.07	8.79 \pm 0.27	10.35 \pm 0.01
	Co(ii) 407.35 \pm 16.19	287.02 \pm 12.98	403.67 \pm 21.68
	Ga(iii) 411.27 \pm 9.96	276.76 \pm 0.48	420.95 \pm 4.44
	Ge(iv) 478.20 \pm 17.96	301.81 \pm 5.32	475.84 \pm 64.68
	Cs(i) 552.28 \pm 4.78	888.29 \pm 1.81	535.87 \pm 12.64

Therefore, screening was performed with the following bitters (Table 3): (i) bitter 1 simulates the expected composition at the TEs recovery unit, (ii) bitter 2 accounts for lower levels of Ca and Mg in the solution (considering higher removal of both elements in the pretreatment), and (iii) bitter 3 simulates a scenario with lower content of major elements (lower concentration factor in the pretreatment). To make the concentration of TEs measurable by the analytical techniques, it was decided to spike the concentration of Li, Co, Ga, Ge, and Cs to 500 $\mu\text{g L}^{-1}$. Inorganic sorbents were only tested using bitters 1 and 2.

Screening of commercial sorbents: sorption and desorption

Sorption experiments for polymeric sorbents were performed by mixing two grams of dried sorbent (in the ionic form indicated in Table 1) and 20 mL of bitter. After 1 h under rotation (60 rpm, Heidolph mixer Reax 2), the supernatant was filtered through a 0.22 μm filter and analyzed, while the sorbent was recovered and put into contact with 10 mL of 1 M HCl for the recovery of the sorbed elements. After another 1 h of rotation, the supernatant was also analyzed. Kinetic experiments (data not shown) have demonstrated that equilibrium was attained within 45 min. Screening was carried out in duplicate for each sorbent for both sorption and desorption, and the pH measurements of the supernatant after the sorption step are collected in Table S1 of the ESI.†

As indicated in Table 1, the preferred option for the application of the most of the ion exchange sorbents selected would be in the sodium form, as the bitters to be treated are having pH values close to neutral values and because the TEs to be removed are at $\mu\text{g L}^{-1}$ levels ($\mu\text{mol L}^{-1}$) and, therefore, the expected changes in pH will be small.

Sorption experiments for inorganic sorbents were performed by mixing 20 mg dried sorbent and 10 mL bitter. Lower amounts of inorganic sorbents were needed compared to polymeric ones due to their higher selectivity. After 1 h overhead rotation (24 rpm, Heidolph overhead mixer), the samples were centrifuged (10 min, 2100 G) and the liquids were recovered by filtration. Desorption studies were carried out by washing the sorbent three times with 5 mL deionized water and centrifugation (10 min, 2100 G) first and then by adding 10 mL desorption solution (0.1 M NaOH for SbTreat and 0.1 M H_2SO_4 for CoTreat, CsTreat, and SrTreat). The experimental procedure was the same as with the sorption studies. The sorption and desorption studies were carried out with up to 3 replicates.

For each target element, sorption removal and desorption recovery efficiencies were calculated as a percentage according to eqn (1) and (2), respectively, based on the ones proposed by Ali *et al.* (2018).⁶¹ In addition, Na sorption removal is provided in Table S2 of the ESI.†

$$\text{Sorption}(\%) = \frac{C_B - C_{\text{eq},S}}{C_B} \times 100 \quad (1)$$

$$\text{Desorption}(\%) = \frac{C_{\text{eq},D} \cdot V_D}{(C_B - C_{\text{eq},S}) \cdot V_B} \quad (2)$$

where C_B is the initial bitter concentration (mg L^{-1}), $C_{\text{eq},S}$ is the equilibrium concentration for sorption (mg L^{-1}), $C_{\text{eq},D}$ is

the equilibrium concentration for desorption (mg L^{-1}), V_D is the volume of desorption solution used (L), and V_B is the volume of bittern used (L).

In addition, to compare the performance or selectivity of the sorbents toward the TEs, distribution coefficients (K_d ($L \text{ kg}^{-1}$)) have been calculated according to eqn (3).⁶²

$$K_d (\text{L kg}^{-1}) = \frac{C_B - C_{\text{eq},S}}{C_{\text{eq},S}} \times \frac{V_B}{m_S} \quad (3)$$

where m_S is the mass of the sorbent (kg).

Analytical methodologies

Major elements were analyzed by Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES; Agilent Technologies 5100 ICP-OES), while minor elements by Inductively Coupled Plasma Mass Spectrometry (ICP-MS; Agilent Technologies 7800 ICP-MS for samples from tests with polymeric sorbents; Thermo Scientific Element 2 ICP-MS for samples from tests with inorganic sorbents). All samples were filtered through $0.22 \mu\text{m}$ filters and diluted with 2% HNO_3 .

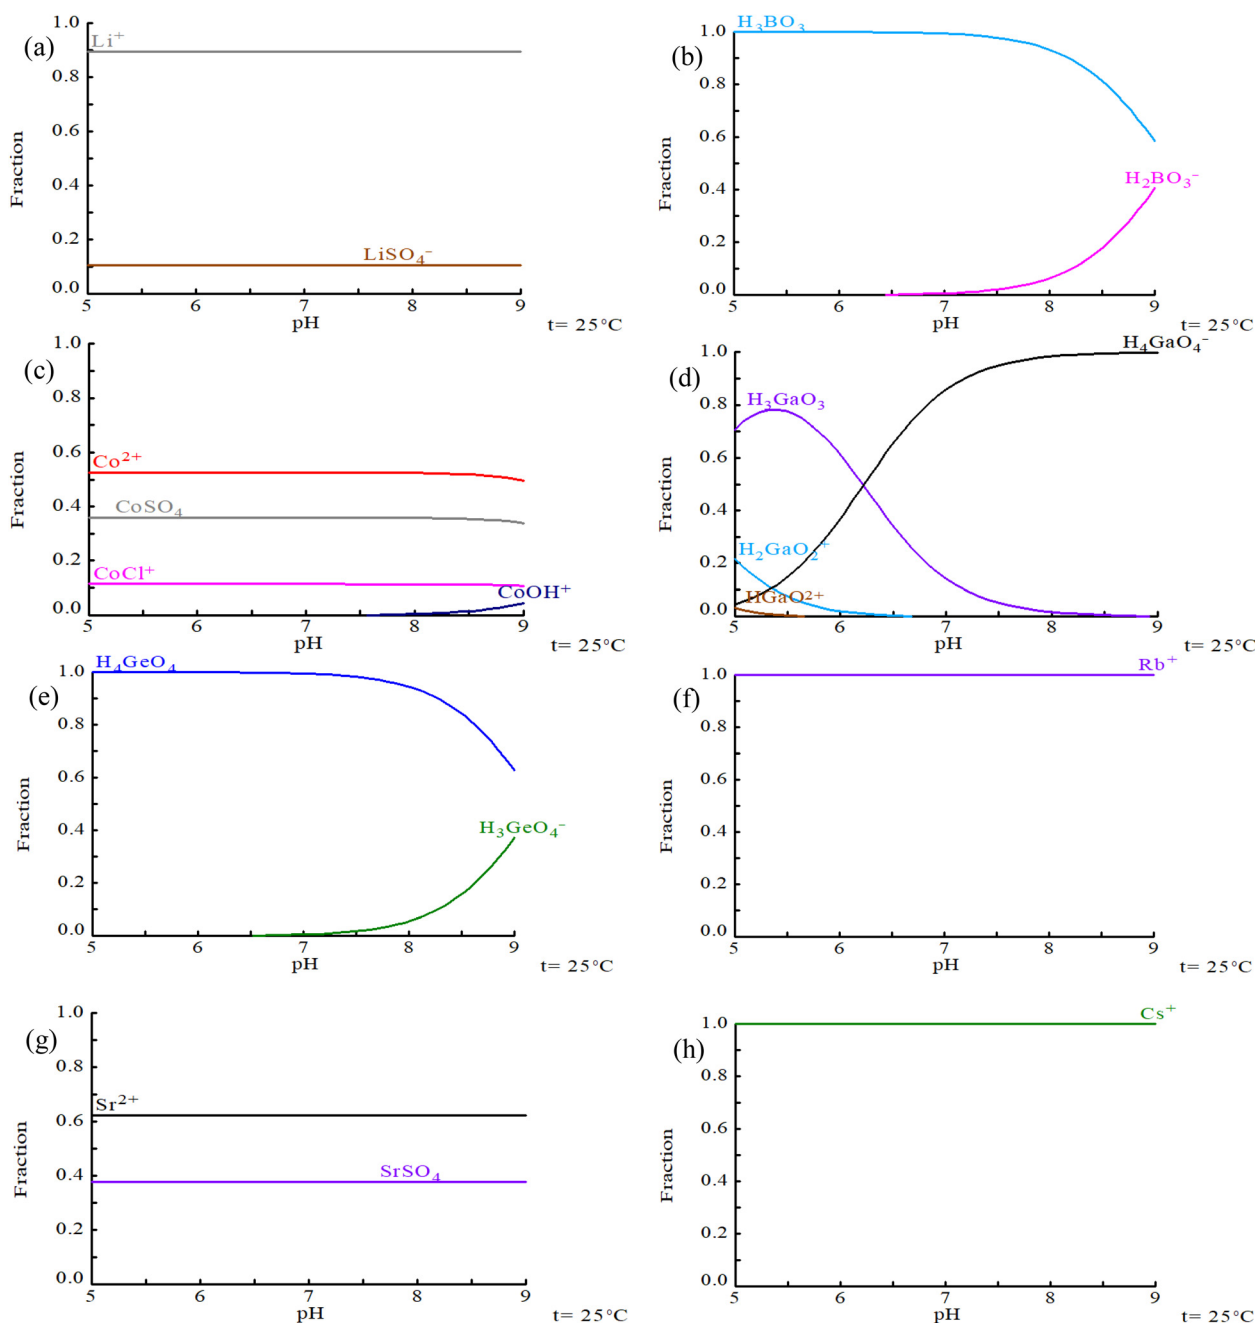

Fig. 2 Speciation diagrams as a function of pH for the TEs in solution: (a) Li, (b) B, (c) Co, (d) Ga, (e) Ge, (f) Rb, (g) Sr, (h) Cs. Composition: bittern 1. Diagrams were built using Hydra/Medusa.⁶³

Results and discussion

Speciation of trace elements in bitters

Initially, a speciation analysis of the TEs in the bittern was carried out using Hydra/Medusa⁶³ since it will determine the extraction mechanisms. From Fig. 2, it can be observed that under the composition of bittern 1 and at pH 7, the TEs present four different behaviors: (i) they are found completely as free ions (e.g., Rb^+ and Cs^+), (ii) they form complexes with sulphate (e.g., $\text{Li}^+/\text{LiSO}_4^-$, and $\text{Sr}^{2+}/\text{SrSO}_4(\text{aq})$), (iii) they form complexes with both chloride and sulphate (e.g., $\text{Co}^{2+}/\text{CoSO}_4(\text{aq})/\text{CoCl}^+$), or (iv) they behave as an oxyanion (e.g., $\text{H}_3\text{BO}_3(\text{aq})/\text{H}_2\text{BO}_3^-$, $\text{H}_3\text{GaO}_3(\text{aq})/\text{H}_4\text{GaO}_4^-$, and $\text{H}_4\text{GeO}_4(\text{aq})/\text{H}_3\text{GeO}_4^-$). No significant changes were found regarding speciation between the different bitters evaluated.

Screening of polymeric sorbents for the recovery of trace elements: sorption and desorption

Tertiary and quaternary amine sorbents. Fig. 3 shows the screening results (both sorption and desorption) of the tertiary and quaternary amine sorbents.

It is expected that due to the positive charge of amine sorbents, negatively-charged species (H_4GaO_4^- for Ga and H_3GeO_4^- for Ge) will be retained. From the experimental results (Fig. 3a–c), it was observed that quaternary amine sorbents (A500Plus, MP500, K6362, and IRA904) did not show affinity toward any of the target elements of interest for the project (removals <10%) and that only appreciable Ga and Ge sorption (25–30%) was achieved by A500Plus with bittern 1 and IRA904 with bittern 3 (25–35%). This would be in accordance with the explanation of Yi-Gong Chen *et al.* (2021),⁶⁴ where it is said that strong basic anion exchangers with quaternary ammonium groups could have good kinetics and short rinses but, in contrast, not a very high exchange efficiency. Among tertiary amine sorbents, IRA94 did not show affinity toward any element, but A100 was able to sorb around 67%, 62%, and 52% Co for bitters 1, 2, and 3, respectively. In addition, MP62 with a tertiary amine group and also MP64, which has both tertiary and quaternary amine functional groups, presented Co sorption that ranged between 72% and 92%. Both sorbents were also able to sorb about 86% Ga and 93% Ge when bittern 1 was evaluated. Yi-Gong Chen *et al.* (2021)⁶⁴ reported that large operating capacity and regeneration efficiency are characteristics of tertiary amine sorbents, while Silva *et al.* (2018)⁶⁵ described mixed anion exchangers (those combining, for example, quaternary ammonium groups with tertiary amines, such as MP64) as sorbents with good metal selectivity and loading capacity.

The sorption mechanisms suggested in reactions (4)–(8) are based on the structure of tertiary and quaternary amine sorbents.⁶⁶ For tertiary amines, Co(II) (in solution as a mixture of $\text{Co}^{2+}/\text{CoSO}_4(\text{aq})/\text{CoCl}^+$) can be retained in the sorbent in its CoCl^+ form by replacing the proton of the amine group (reaction (4)), as reported by Wołowicz and Hubicki (2018).⁶⁷ However, as suggested by Chirskt *et al.* (2013),⁶⁸ H_4GaO_4^- would completely replace the chloride present in the tertiary amine (reaction (5)). In the case of Ge, it is proposed that H_4GeO_4 will lose a proton

to form a bond with the free amine group, also replacing the chloride present in the tertiary amine (reaction (6)). In the case of quaternary amines, Höll (2011)⁶⁹ reported that the chloride atom is replaced by other anion species. Therefore, reactions (7) and (8) are suggested as Ga and Ge sorption mechanisms.

Regeneration of the sorbents was carried out using 1 M HCl (Fig. 3d–f). During regeneration, Co retained in A100 was recovered by more than 70% with bittern 1 and completely recovered (>99%) with bitters 2 and 3. Regarding MP62 and

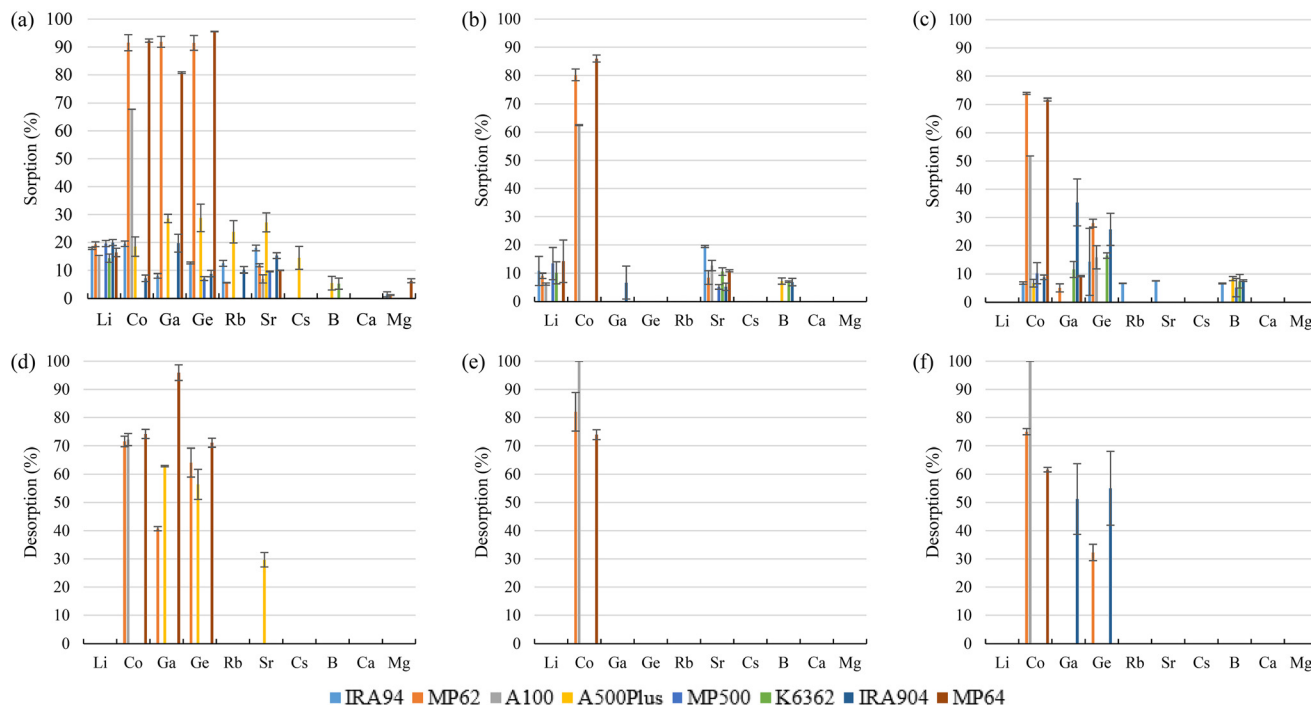

Fig. 3 Screening of tertiary and quaternary amine sorbents regarding the sorption using the bittens (a) 1, (b) 2, and (c) 3 and desorption of the sorbents after having tested the bittens (d) 1, (e) 2, and (f) 3. Contact time was 1 h. Desorption solution was 1 M HCl.

MP64, recoveries over 60% were achieved for Co and, in the case of bittens 1, also for Ge. When testing bittens 1, Ga recovery was about 40% for MP62 and 96% for MP64. About 60% Ga and Ge was desorbed from A500Plus after using bittens 1, and about 53% from IRA904 after evaluating bittens 3. However, it must be borne in mind that these two sorbents presented sorption efficiencies below 30% for the other TEs. Accordingly, tertiary resins are preferred over quaternary ammonium resins from the perspective of being used to recover those elements in the form of oxyacids, as in the case of Ga and Ge.

Carboxylic with amine sorbents. K3 and K5 belong to fibrous sorbents with carboxylic acid functional groups but with amines on their structure. These kind of fibrous ion exchangers, due to their mechanical strength and flexibility,⁷⁰ are applied for air purification,⁶⁴ but they could also be used to extract several metals from water.⁷¹ Independent of which bittens were tested (Fig. 4), K3 was able to sorb 52–55% Co, 72–82% Ga, and 30–32% Ge, but Ge sorption decreased to 24% in bittens 3. K5 achieved sorption values over 90% for Co and Ga when bittens 1 and 2 were tested and about 85% with bittens 3. Apart from that, 29% of Sr with bittens 1 and about 51% of both Rb and Sr with bittens 3 were also achieved in terms of sorption. This increase in sorption can be related to the fact that Mg concentration was decreased in bittens 2 and to a lower concentration of major elements in bittens 3. The fact that both sorbents have shown from moderate to high extraction capacities for transition (Co) and post-transition elements (Ga and Ge), while more limited extraction removal reactions for earth-alkaline (Sr) and alkaline (Rb) is an indication of the complexing role of the carboxylic group over the

free amine groups. These two last metals have lower selectivity factor compared to Ca and Mg, present at much higher concentration than Sr and Rb. The sorption removals obtained were in concordance with the results reported by Soldatov *et al.* (1999),⁴³ where other two similar carboxylic and amino-carboxylic fibrous resin (FIBAN K4 and AK22) were used together and up to 89% Co was retained. The fact that these sorbents could retain either cations or oxyanions is related to their amino-carboxylic polyampholyte functional groups.⁴³

Two suggested mechanisms of carboxylic sorbents for Co and Sr are represented as a general bivalent metal cation M^{2+} , depending on if it is bonded to only one (reaction (9)) or two carboxylic groups (reaction (10)). In the case of Rb, which at the prevailing pH was present as a monovalent cation (Rb^+), it will replace the hydrogen of the carboxylic group. Then, reactions (11)–(14) represent the suggested mechanisms on how the sorbent could retain Ga (reactions (11) and (12)) and Ge (reactions (13) and (14)), depending on if they are bonded to one or two carboxylic groups. These mechanisms are suggested based on the metal ion binding options for a carboxylate group presented by Lawrence (2010)⁷² and Zagorodni (2007).⁷³

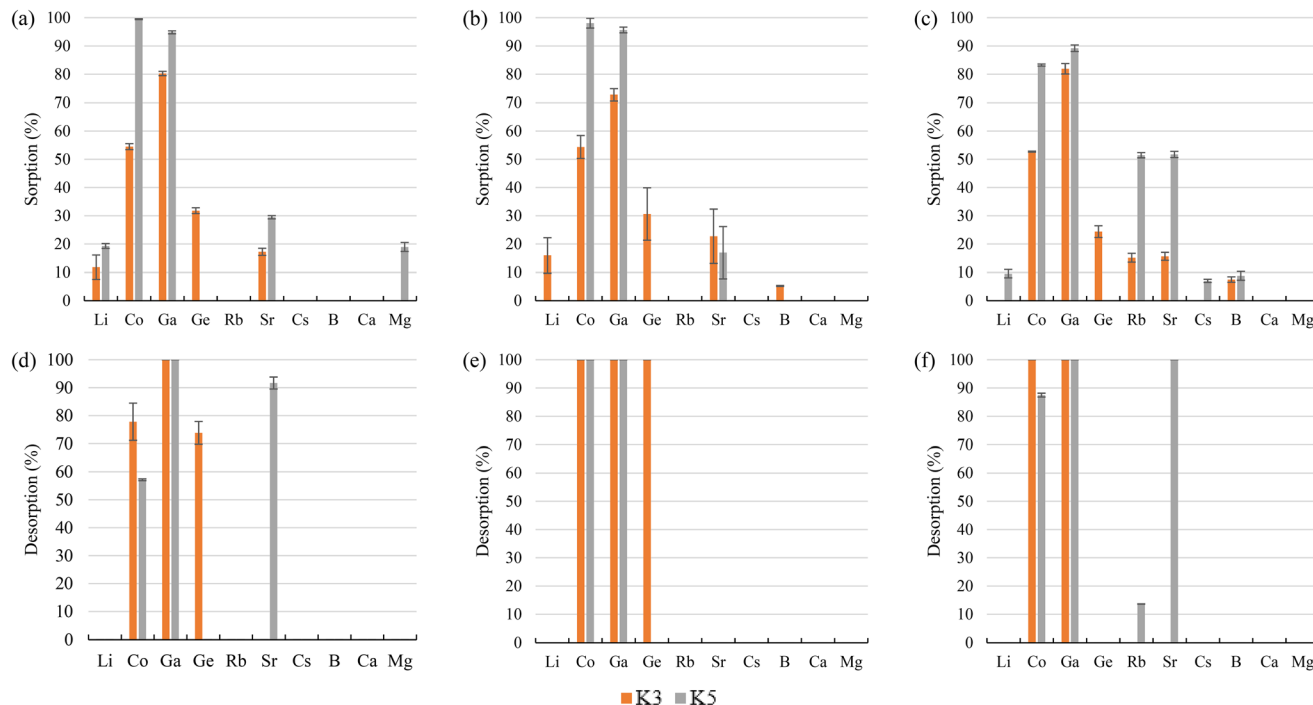

Fig. 4 Screening of carboxylic with amines sorbents regarding the sorption using the bittern (a) 1, (b) 2, and (c) 3 and desorption of the sorbents after having tested the bittern (d) 1, (e) 2, and (f) 3. Contact time was 1 h. Desorption solution was 1 M HCl.

Regarding the desorption stage, it was possible to recover 78% Co, >99% Ga, and 74% Ge from K3 when bittern 1 was

tested. When bitters 2 and 3 were used, all elements sorbed were completely recovered (>99%). When K5 was evaluated, the desorption recoveries were over 87% for all elements excluding Co (57%) for bittern 1 and Rb (13%) for bittern 3.

Sulphonic sorbents. Sulphonic sorbents have been used to extract alkali and earth-alkali metals (*e.g.*, Rb^+ , Sr^{2+} , and Cs^+) from low salinity streams. Hubicki and Kołodyńska (2012)⁷⁴ reported the following affinity series, where only the elements of interest for this project and those present in the bittern as major elements were considered: $\text{Sr}^{2+} > \text{Ca}^{2+} > \text{Co}^{2+} > \text{Mg}^{2+} \gg \text{Cs}^+ > \text{Rb}^+ > \text{K}^+ > \text{Na}^+ > \text{H}^+ > \text{Li}^+$. However, the sulphonic sorbents tested in the current study presented (Fig. 5) low sorption (<40%) for all elements with bittern 1. By decreasing the levels of Ca and Mg (bittern 2), no significant changes were observed in the sorption stages. This would indicate that the levels of Ca and Mg in bittern 1, despite being considered as major elements, were relatively low concentrated compared to the others and, in consequence, they did not appreciably affect in the sorption of the other elements. Nevertheless, by decreasing the concentration of major elements (*e.g.*, Na^+ and K^+) (bittern 3), the sorption values improved up to 66%, except for S100, which did not even achieve 40%. In addition, when bittern 3 was tested, C160 was able to sorb 42% Co and K2629 could retain 33% Ga. The results indicated that the selectivity factors are strongly influenced by the high contents of Na and K in the bitters. The affinity series aforementioned confirmed the results obtained in this study, where the highest sorption value obtained was for Sr^{2+} for the three bitters tested. However, despite being the most retained element, it did not stand out so

Fig. 5 Screening of sulphonic sorbents regarding the sorption using the bittren (a) 1, (b) 2, and (c) 3 and desorption of the sorbents after having tested the bittren (d) 1, (e) 2, and (f) 3. Contact time was 1 h. Desorption solution was 1 M HCl.

much from the other retained elements, a fact that was already announced by Silva *et al.* (2018)⁶⁵ when they reported that sulphonic sorbents presented poor metal selectivity.

Considering the sulphonic sorbents structure and the mechanism suggested by Taha (2021),⁷⁵ Sikora *et al.* (2021),⁷⁶ and Zhang *et al.* (2022),⁷⁷ the suggested mechanisms for Co and Sr sorption are represented in reactions (15) and (16) depending on whether they are bonded to one or two functional groups. A similar mechanism to the one described in reaction (15) is expected for Cs and Rb (as Cs⁺ and Rb⁺) by the substitution of the Na⁺ in the sorbent functional groups obtaining, in that case, a neutral molecule. Then, regarding Ga, similar mechanisms are suggested in reactions (17) and (18).

Most of the sulphonic sorbents used were in the sodium form. Therefore, that was the form applied in the suggested mechanisms. Nevertheless, it must be noticed that K2629 was used in its acidic form. Consequently, although the sorption reactions were expected to be similar, a slight sorption of Na (<8%) was observed, which could be explained by the substitution of H⁺ by the Na⁺ from the bittrens.

Regarding desorption, it was not possible with either bittren 1 or 2 to recover more than 37% of the elements sorbed. It was only possible to recover significant amounts of

the TEs of interest after using bittern 3. For example, 40% Co and 50% Cs were desorbed from C160 and S100, respectively. The other sorbents presented lower desorption values for TEs (<40%). These low desorption results were not surprisingly as Silva *et al.* (2018)⁶⁵ also reported that sulphonic sorbents presented difficulties to elute the adsorbed metals.

Phosphinic, phosphonic, and aminophosphonic sorbents.

Phosphonic and aminophosphonic sorbents have been reported to be selective toward alkaline, earth-alkaline, and transition metals (*e.g.*, Co^{2+} , Sr^{2+} , Rb^+ , and Cs^+). They are characterized by the strong, stable, and specific interaction that polyvalent metals could do with the two hydroxyl groups of the phosphonic group, forming a four-membered chelate ring.^{65,74} Fig. 6 shows the results of both sorption and desorption stages.

S957 has not only sulphonic but also phosphonic functional groups. Their sulphonic groups justify similar sorption values to the ones achieved with sulphonic sorbents for most elements of interest. However, although sulphonic sorbents did not have affinity for Ga, S957 phosphonic groups explain their good Ga sorption (>92%) for the three bitterns tested. Despite the extremely high Ga sorption, it was not desorbed. This behavior was the one expected, as Chiariza *et al.* (1997)⁷⁸ had reported that phosphonic sorbents and those having both phosphonic and sulphonic groups had higher adsorption properties than sorbents having only sulphonic ligands. However, the strong interaction that metals could have with the phosphonic group causes some difficulties to elute them.⁷⁹

Considering its structure and the evidences reported by Amphlett *et al.* (2020),⁸⁰ a suggestion on how S957 could retain Sr and Ga are represented in reactions (19) and (20), respectively.

In that case, a small amount of Na sorption was also observed, which could be probably related with the presence of sulphonic groups in the sorbent. However, it must be highlighted that Na removal (<6%) is noticeably lower than the other retained elements.

S940 and IRC747 have other similar functional groups, *i.e.*, aminophosphonic groups. In this case, sorption over 80% was achieved for Co, Ga, and Sr for all bitterns tested. Both sor-

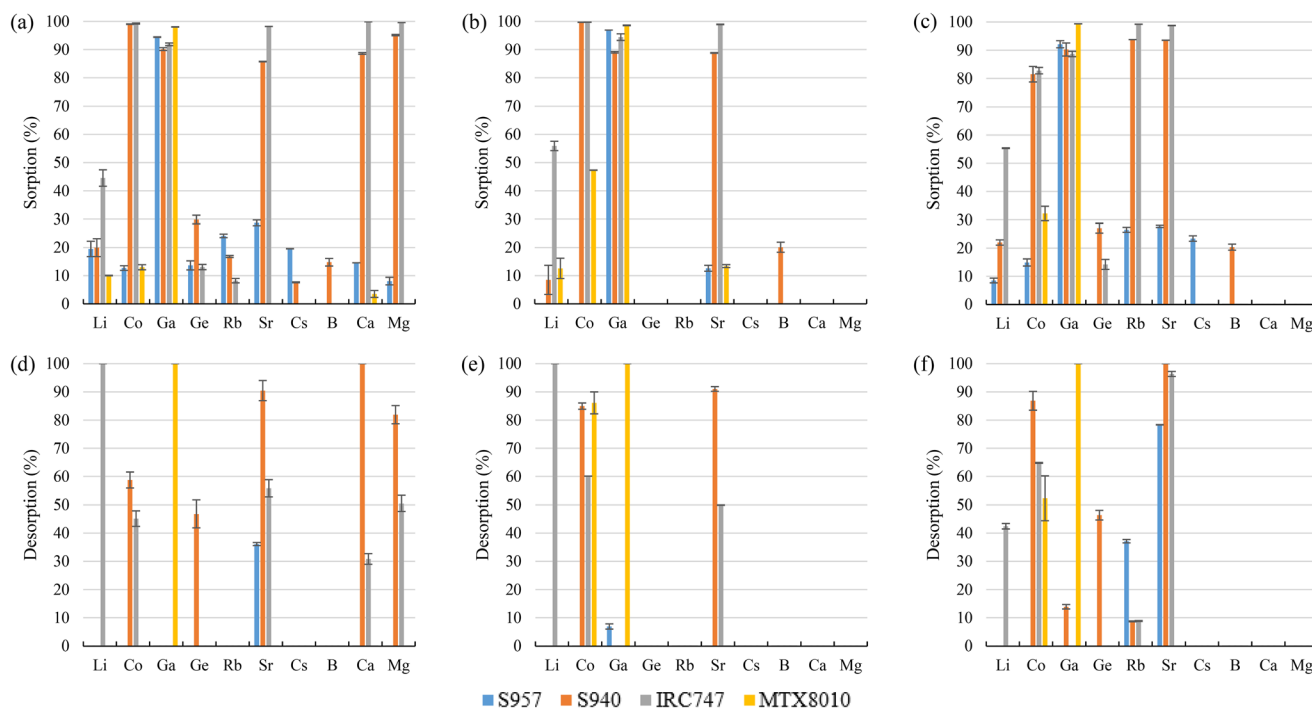

Fig. 6 Screening of phosphinic, phosphonic, and aminophosphonic sorbents regarding the sorption using the bittern (a) 1, (b) 2, and (c) 3 and desorption of the sorbents after having tested the bittern (d) 1, (e) 2, and (f) 3. Contact time was 1 h. Desorption solution was 1 M HCl.

Iminodiacetic sorbents. Another large group of sorbents tested are those whose functional group is iminodiacetic acid, which are considered as chelating sorbents. This kind of sorbents (results shown in Fig. 7) showed extremely good affinity toward Sr as its sorption was over 98% for each sorbent and bitttern tested. Excluding sorption of about 80% for Co using bitttern 3, all sorbents were able to sorb it more than 97%. A similar behavior was also observed for Ga, which was normally sorbed by more than 80% when bittterns 1 and 2 were analyzed but about 70% when bitttern 3 was tested. However, S9320 presented a lower Ga sorption in the presence of bittterns 2 and 3, as it took only 60% and 45% Ga, respectively. Among the four

Another sorbent included in the study was MTX8010, which is an impregnated sorbent with bis-(2,4,4-trimethylpentyl-) phosphinic acid. MTX8010 was extremely selective toward Ga as it was the only element that was completely sorbed (>98%). Co sorption was below 15% when bittern 1

Fig. 7 Screening of iminodiacetic sorbents regarding the sorption using the bittern (a) 1, (b) 2, and (c) 3 and desorption of the sorbents after having tested the bittern (d) 1, (e) 2, and (f) 3. Contact time was 1 h. Desorption solution was 1 M HCl.

iminodiacetic sorbents tested, TP207 and TP208 also presented some affinity toward Li as both of them were able to sorb it about 47% from bittern 1 and between 61% and 73% from the other two bitterns. Between the other two sorbents, only S9320 presented a relevant sorption value of 47% for Li when bittern 3 was tested. Finally, almost no sorption was observed for Rb among this kind of sorbents for bitterns 1 and 2, but they were able to sorb it by more than 99% when bittern 3 was analyzed. This evidence might be explained by a higher concentration of Rb in bittern 3 (10.28 mg L^{-1}) than in bitterns 1 and 2 ($2.3\text{--}3.5 \text{ mg L}^{-1}$) in addition to a lower competition of Ca, Mg, and other major elements. Consequently, the fact that Rb sorption increased caused some competition with other elements that were slightly less sorbed in bittern 3, such as Co.

The results obtained were in accordance with the data provided in the data sheets of the sorbents, where their affinity series was presented as $\text{Co}^{2+} > \text{Ca}^{2+} > \text{Mg}^{2+} > \text{Sr}^{2+}$, although in this case, Sr^{2+} was better retained than Co^{2+} . In addition, Yuchi *et al.* (1997)⁸³ reported that iminodiacetic sorbents could sorb and have high affinity for trivalent metal ions such as Ga^{3+} or Fe^{3+} . This fact could be useful to confirm the evidence of this study as, although in the bitterns Ga tends to be as oxanion, it maintains the trivalent oxidation state.

A general mechanism that could be suitable for Co and Sr and another one for Ga are suggested in reactions (26) and (27), respectively. Then, as some iminodiacetic sorbents were able to sorb Li, a suggested mechanism for it is shown in reaction (28).

These three mechanisms are based on the ones presented by Zagorodni (2007).⁷³

Despite the good Sr sorption among these sorbents, only 55–70% of it could be recovered from them during desorption

after bitters 1 and 2 were evaluated (only 35–37% for TP208). However, it could be possible to desorb it completely when bitter 3 was tested (only 53% for TP208). Desorption of Co ranged between 35% and 70% for S9320 and TP207, respectively. However, about 64% of Co for bitter 1 and 90% for bitters 2 and 3 was possible to be recovered from IRC748. No Co desorption was observed for TP208. Only IRC748 was able to desorb Ga, which achieved desorption recoveries of 50%, 40%, and 22% for bitters 1, 2, and 3, respectively. Li desorption ranged between 74% and >99% (37% for TP207 when bitter 3 was tested). No Li desorption was observed for IRC748 when bitters 1 and 2 were analyzed (it must be considered that its sorption was only about 15%). Practically no desorption was observed for Rb (that was only sorbed when testing bitter 3) in any sorbent.

N-Methylglucamine sorbents. Three sorbents with N-Methylglucamine functional groups were also included in the study, which have proven to have high selectivity toward B.^{84,85} The three sorbents tested (S108, CRB03, and CRB05) presented a similar behavior (Fig. 8). Practically, these sorbents only showed affinity toward B and Ge (with removals >96% for all bitters with the exception of 80–92% for Ge in bitter 3) and for Co and Ga (with removals generally in the range of 45–78%). Finally, and only in the case of bitter 2, Sr sorption of about 34% was observed, which would be explained by the less competition of Co, Ga, and Ge as their concentrations were slightly lower than the ones in bitters 1 and 3. No relevant changes were observed among the three bitters evaluated. These results were in concordance with the lit-

erature, as Melnyk *et al.* (2005)⁸⁶ reported that N-Methylglucamine sorbents have an efficiency for B removal ranging in the range of 93–98% and with Schilde and Uhlemann (1993),⁸⁷ who demonstrated that several oxyanions could also be retained by this type of sorbents.

According to the literature,⁸⁸ a bidentate extraction mechanism for $\text{H}_3\text{BO}_3(\text{aq})$ is postulated as shown in reaction (31).

Taking into account that both Ge and Ga presented a similar structure as $\text{H}_3\text{BO}_3(\text{aq})$ (*i.e.*, H_4GaO_4^- for Ga and $\text{H}_4\text{GeO}_4(\text{aq})$ for Ge), similar sorption mechanisms are postulated, as shown in reactions (30) and (31), respectively.

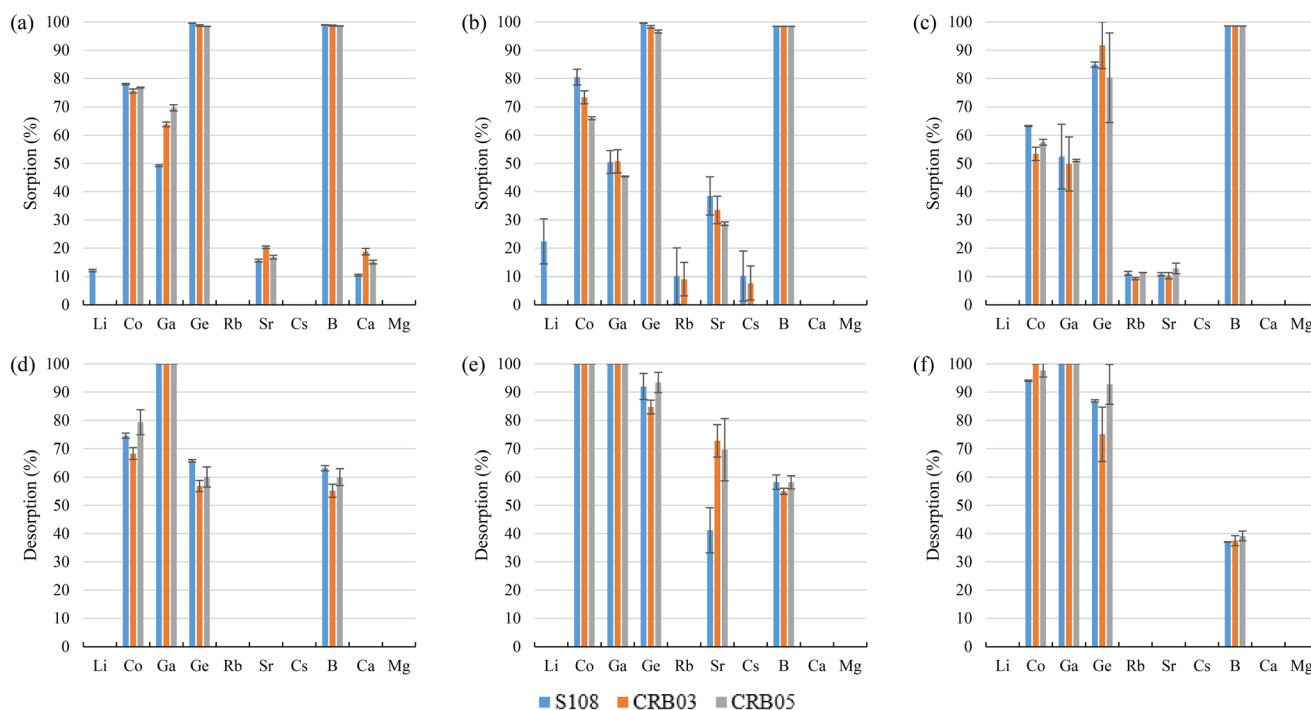

Fig. 8 Screening of N-Methylglucamine sorbents regarding the sorption using the bitter (a) 1, (b) 2, and (c) 3 and desorption of the sorbents after having tested the bitter (d) 1, (e) 2, and (f) 3. Contact time was 1 h. Desorption solution was 1 M HCl.

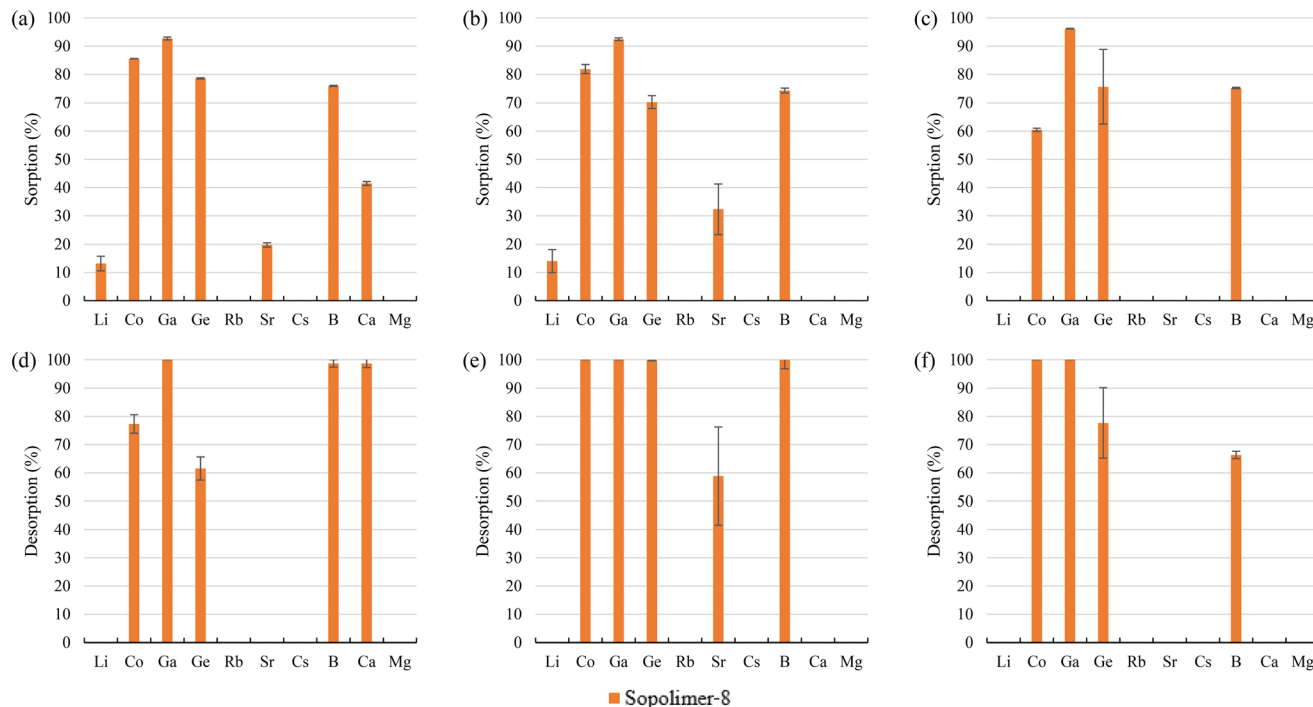

Fig. 9 Screening of *N*-Methylpyridine sorbent regarding the sorption using the bittren (a) 1, (b) 2, and (c) 3 and desorption of the sorbents after having tested the bittren (d) 1, (e) 2, and (f) 3. Contact time was 1 h. Desorption solution was 1 M HCl.

However, Co(II) is not found in the solution as the oxanion; instead, it is mostly present as Co^{2+} . Therefore, it is expected to be extracted, as shown in reaction (32).

Using 1 M HCl, Co and Ga were almost completely recovered (>94%) from the sorbents, excluding 68–80% desorption of Co for bittren 1. Regarding Ge desorption, 56–66% for bittren 1 and 75–94% for bittrens 2 and 3 was achieved. However, B desorption was about 55–64% for bittrens 1 and 2 and 37–39% for bittren 3. Finally, although S108 only reached a value of 41%, Sr desorption of about 69–73% was achieved with CRB03 and CRB05 after using bittren 2, which was the only one in which Sr was appreciably (>25%) sorbed.

***N*-Methylpyridine.** Finally, Sopolimer-8 (Fig. 9), whose functional group is *N*-Methylpyridine, presented sorption removals of about 92–97%, 70–79%, and 74–76% for Ga, Ge, and B, respectively. This sorbent also presented Co sorption that ranged between 60% and 86%. The removal of 32% of Sr was also observed when bittren 2 was tested. Regarding desorption, all Ga was recovered. Although Ge desorption was over 99% for bittren 2, it was about 62% and 78% for bittrens 1 and 3, respectively. Desorption values over 98% were achieved regarding B when bittrens 1 and 2 were tested, but only 66% was recovered for bittren 3. When bittren 1 was used, Co was possible to be desorbed by a 77%, but it was completely recovered when bittrens 2 and 3 were analyzed. The Sr sorbed with bittren 2 was later desorbed by 59%.

Suggested mechanisms for Co, Ga, Ge, and B sorption are presented in reactions (33), (34), (35), and (36), respectively.

Screening of inorganic sorbents for the recovery of trace elements: sorption and desorption

Fig. 10 shows both the sorption and desorption screening results of the inorganic sorbents, namely, SbTreat, CoTreat, CsTreat, and SrTreat. The SbTreat results showed that efficient sorption (>80%) was achieved for Ga and Ge from bittern 1. Similar behavior was seen also for bittern 2, indicating that the presence of Mg and Ca did not affect the sorption efficiency. This high uptake of Ga and Ge was expected because of their oxyanionic speciation and the anionic exchange character of zirconia-based material.⁸⁹ Based on the results observed, the sorption mechanism is believed to be partly by anion uptake and partly by complexation. The desorption studies (carried out using 0.1 M NaOH) yielded 60% recovery for Ga, but no desorption of Ge was observed. However, 24 h contact time with other desorption solutions (*i.e.*, 1 M and 0.1 M NH_3 , H_2SO_4 , and HCl ; data not shown) exhibit 60–70% desorption with acid (1 M and 0.1 M H_2SO_4) for Ge, whereas 40–60% desorption was achieved with both acid and base (0.1 M and 1 M H_2SO_4 and NaOH). A maximum desorption of 25% for Ge was achieved when HCl was used as the desorption solution, whereas Ga desorption was below 5%. However, the desorption for both Ga and Ge was below 5% when the desorption solution was NH_3 . The results show that even though Ga and Ge desorption mechanisms are different,

both elements can be efficiently recovered from SbTreat using 1 M or 0.1 M H_2SO_4 and NaOH.

Due to their similar chemical structure, both CoTreat and SrTreat were expected to show similar metal uptake with difference in their target elements Co and Sr. The highest metal uptake (36–47%) for these materials was observed for Ge, which was higher compared to Co or Sr for which these materials are targeted. Surprisingly, the absence of Ca and Mg in bittern 2 did not increase the Co or Sr uptake significantly, even though Ca is known to compete with Sr uptake. The difference in Co uptake can be explained by the materials affinity for H^+ ions. In the case of CoTreat samples, the average pH was 6.8, whereas the average pH in the SrTreat ones was 7.8, exhibiting approximately 5 times higher sorption percentage for Co. The sorption percentages for Sr were similar for CoTreat and SrTreat (<5%). It is worth to remember that the original concentrations of Co and Sr in biterrens were significantly different, as the former was at $\mu\text{g L}^{-1}$ whereas the latter was at mg L^{-1} levels. In addition, CoTreat sorbed about 30% Ga from both biterrens. Despite the low sorption for the targeted elements (<10% Co for CoTreat and <13% Sr for SrTreat), desorption ranged between 70% and 95% for CoTreat and it was about 95% with bittern 1 and 40% with bittern 2 when testing SrTreat. Lehto *et al.* (1999)⁹⁰ observed that very low Sr sorption occurred at neutral pH when using SrTreat and that, in addition, whereas K^+ , Li^+ , and Mg^{2+} did not highly affect Sr uptake, Ca^{2+} strongly decreased its retention. Therefore, as the biterrens in this study were at pH 7, this may be the reason why Sr removal from them was so low and why it increased a bit when Ca^{2+} was not present (bittern 2), even when they were still at neutral pH. Regarding the CoTreat sorbent, Co, Ga, and Ge removal were slightly improved when changing from bittern 1 to bittern 2. In that case, Harjula *et al.* (2003)⁹¹ also reported that Ca presence produced a Co decreasing sorption as both of them compete in ion-exchange processes due to the similarity of their hydrated ionic radius.

The results for CsTreat showed sorptions of 33% Ga, 45% Ge, and 40% Rb, apart from an excellent sorption achieved for Cs (90%). The uptake mechanism of Cs on CsTreat (hexacyanoferrate-type material) has been explained by the tight fit of Cs ion inside the cavities of its structure, which does not allow its release in the desorption stage.⁹² In fact, the elements retained by the sorbent were not desorbed from it. In addition, the release of Co from the CsTreat structure occurred with the degradation of the sorbent. The desorption studies of CsTreat were continued with several acids and bases, but only maximum of 1% and 15% desorption was achieved for Cs and Rb, respectively. The retention of Cs could be done either by co-precipitation or ion-exchange, although the latter seems to be more efficient.⁹³ Hexacyanoferrate(II) compounds, most of them with K^+ in the cavities of their cubic structure, are the most suitable ones regarding Cs sorption due to their high selectivity toward that element, their low cost, and their thermal and radiation stability, apart from their fast kinetics.^{94,95} Then, taking into account the structure of the sorbent, the literature considers that the main mechanism for

Fig. 10 Screening of inorganic sorbents regarding the sorption using the bittren (a) 1 and (b) 2 and desorption of the sorbents after having tested the bittren (c) 1 and (d) 2. Contact time was 1 h. Desorption solutions were 0.1 M NaOH for SbTreat and 0.1 M H₂SO₄ for CoTreat, CsTreat, and SrTreat. * Co results for CsTreat are not shown as Co was released from the structure of the sorbent.

Cs sorption is the K⁺ replacement in the sorbent by the Cs⁺ present in the solution by ion-exchange.^{96,97}

Comparison and characterization of the selected polymeric and inorganic sorbents

The screening results allowed selecting which polymeric and inorganic sorbents presented a good behavior regarding the sorption and desorption of TEs, taking into account a minimum sorption of 70% and/or having affinity toward a specific or single element. Therefore, the following polymeric sorbents were selected: (i) tertiary amine MP62; (ii) tertiary and quaternary amine MP64; (iii) aminophosphonic S940 and IRC747; (iv) the impregnated sorbent with bis-(2,4,4-trimethylpentyl-) phosphinic (MTX8010); and, (v) the

N-Methylglucamine sorbents (CRB03, CRB05, and S108). The inorganic sorbents selected for further studies were SbTreat and SrTreat. CsTreat was shown to be an efficient sorbent for Rb and Cs, whereas poor desorption capabilities prohibited their use in this application. SrTreat was selected over CoTreat because, even though they are chemically similar, SrTreat exhibited higher sorption capabilities.

Considering that the main sorption mechanisms for the TEs of interest were by ligands to a specific group in the case of polymeric sorbents and by inletting into the structure cavities in the case of inorganic ones, the distribution coefficients (K_d) for each of the selected sorbents is collected in Table 4. Apart from the TEs, Ca and Mg have been included, as they are the most competing elements in the sorption process. For

Table 4 Distribution coefficients (K_d ; L kg⁻¹) for the selected polymeric and inorganic sorbents, determined from data from screening performed with bittren 1

	B(III)	Ca(II)	Mg(II)	Li(I)	Co(II)	Ga(III)	Ge(IV)	Rb(I)	Sr(II)	Cs(I)
MP62	0	0	0.1	2	115	116	113	0.6	1	0.2
MP64	0	0	0.7	2	120	42	213	0.3	1	0
S940	2	78	195	3	991	92	4	2	60	0.8
IRC747	0.2	7691	2234	8	1343	113	2	0.9	545	0.1
MTX8010	0	0.4	0	1	2	504	0	0	0.1	0
S108	972	1	0	1	35	10	2644	0	2	0
CRB03	778	2	0	0	31	18	795	0	3	0
CRB05	711	2	0	0	33	23	637	0	2	0
SbTreat	14	0	0	22	0	2800	2033	0	3	0
SrTreat	6	16	9	62	178	43	382	11	17	7

example, MP62 and MP64 (both with amine functional groups) presented K_d values ranging between 42 and 213 L kg⁻¹ for Co(II), Ga(III), and Ge(IV). IRC747 (aminophosphonic sorbent) has good affinity toward Co(II) ($K_d \geq 1343$ L kg⁻¹), Ga(III) ($K_d \geq 113$ L kg⁻¹), and Sr(II) ($K_d \geq 545$ L kg⁻¹), but also for Ca(II) and Mg(II), demonstrating that they are the main competing elements. The other aminophosphonic sorbent, S940, has similar K_d values for Co(II) and Ga(III) but lower ones for Ca(II) and Mg(II). Although the value for Sr(II) also decreased, it still was the second largest one regarding this element. MTX8010 has selectivity practically toward only Ga(III) (504 L kg⁻¹). *N*-Methylglucamine sorbents (*i.e.*, S108, CRB03, and CRB05) presented certain affinity (K_d in the range of 10–35 L kg⁻¹) to Co(II) and Ga(III), but they are selective toward B(III) and Ge(IV) ($K_d \geq 637$ L kg⁻¹). In addition, inorganic sorbents are also extremely selective, as SrTreat reported K_d over 170 L kg⁻¹ for Co(II) and Ge(IV) and SbTreat presented K_d over 2000 L kg⁻¹ for Ga(III) and Ge(IV).

It must be highlighted that the distribution coefficients were determined with the screening results of bittern 1 (the most unfavorable case). It is expected that these values increase as, for example, by achieving higher removal ratios of Ca and Mg. For example, Vassallo *et al.* (2021)⁹⁸ reported the removal percentages of Ca and Mg of 98.5% and >99.9% from brines, respectively.

Conclusion

This study identified the most selective functional groups toward TEs (Li, B, Co, Ga, Ge, Rb, Sr, and Cs) present in the bitterns generated in solar sea saltworks by a screening (sorption and desorption) with synthetic bitterns with different conditions (*i.e.*, levels of Ca and Mg, and major elements). For example, it was observed that the quaternary and/or tertiary amine functional groups as well as sulphonic sorbents showed low sorption of TEs. Sorbents containing carboxylic with amine groups showed a good performance for targeting Co and Ga (>90%, with bitterns 1 and 2). In relation to phosphonic sorbents, the best performance was achieved with the aminophosphonic ones, allowing to recover Co and Sr. In addition, the impregnated sorbent with the phosphinic acid (MTX8010) showed an extremely good affinity for Ga with both sorption and desorption over 98%. Iminodiacetic sorbents showed Sr sorption over 98% in all the bitterns, but its complete desorption was not achieved. In addition, the *N*-Methylglucamine and *N*-Methylpyridine sorbents presented good affinity toward B, Co, Ga, and Ge. No polymeric sorbents with high affinity toward Li, Cs, and Rb were found.

It was observed that one critical parameter during the operation, which will affect the affinity and selectivity of the sorbents, are the levels of Ca and Mg in solution. In addition, the concentration of major elements can also have a noticeable impact on TEs extraction, as sorption removal efficiencies generally increased at lower concentration of major elements.

The experimental results allowed to select the polymeric sorbents that were the most promising ones for recovering the TEs: (i) tertiary amine MP62; (ii) tertiary and quaternary amine MP64; (iii) aminophosphonic S940 and IRC747; (iv) impregnated sorbent with bis-(2,4,4-trimethylpentyl-) phosphinic acid MTX8010; and, (v) the *N*-Methylglucamine sorbents (S108, CRB03, and CRB05). Distribution coefficients of some TEs have shown values up to 2644 L kg⁻¹, showing the possibility of recovering them.

Regarding the inorganic sorbents, zirconium oxide (SbTreat) showed excellent (>80%) sorption for Ga and Ge. The desorption results suggested different uptake mechanisms for both of them since Ga was desorbed with both acid and base (*i.e.*, H₂SO₄ and NaOH), whereas Ge was desorbed with only acid (*e.g.*, H₂SO₄). The sodium titanium oxide sorbents showed good uptake for Co (about 25% with SrTreat) and Ge (about 40% for both SrTreat and CoTreat), whereas Sr sorption was low (<13%). However, the original Sr composition in bittern 1 was almost 30 times higher compared to Co, and Sr uptake for these materials is known to be interfered by Ca ions. The potassium hexacyanoferrate compound (CsTreat) showed excellent sorption for Cs and it could also sorb Rb, but its desorption was negligible.

A comparison of K_d values show that inorganic sorbents have as much capacity as polymeric ones to retain the targeted TEs as they are in the same orders of magnitude. However, desorption recoveries are generally much higher for polymeric sorbents than those for inorganics.

The selection of suitable sorbents for TEs recovery from saltworks bitterns will be based on: (i) a trade-off between sorption and desorption efficiencies; (ii) the need to use further separation stages as the selectivity factors are not high enough to achieve the individual separation of the selected group of TEs. Therefore, the selected sorbents will continue to be studied regarding equilibrium and kinetics parameters and column performance testing different bitterns.
