Theoretical insights into NH₃ absorption mechanisms with imidazolium-based protic ionic liquids†

Wenhui Tu,^a Shaojuan Zeng,*ab Yinge Bai,ab Xiaochun Zhang,a Haifeng Dongab and Xiangping Zhang ** *abc

lonic liquids (ILs) provide a promising way for efficient absorption and separation of ammonia (NH₃) due to their extremely low vapor pressures and adjustable structures. However, the understanding of absorption mechanisms especially in terms of theoretical insights is still not very clear, which is crucial for designing targeted ILs. In this work, a universal method that integrates density functional theory and molecular dynamic simulations was proposed to study the mechanisms of NH₃ absorption by protic ionic liquids (PILs). The results showed that the NH₃ absorption performance of the imidazolium-based PILs ([BIm][X], $X = Tf_2N$, SCN and NO_3) is determined by not only the hydrogen bonding between the N atom in NH $_3$ and the protic site (H-N 3) on the cation but also the cation-anion interaction. With the increase in NH_x absorption capacity, the hydrogen bonding between [BIm][Tf₂N] and NH_x changed from orbital dominated to electrostatic dominated, so 3.0 mol NH3 per mol IL at 313.15 K and 0.10 MPa was further proved as a threshold for NH₃ capacity of [BIm][Tf₂N] by the Gibbs free energy results, which agrees well with the experimental results. Furthermore, the anions of [BIm][X] could also compete with NH3 for interaction with H-N3 of the cation, which weakens the interaction between the cation and NH3 and then decreases the NH₃ absorption ability of PILs. This study provides further understanding on NH₃ absorption mechanisms with ILs, which will guide the design of novel functionalized ILs for NH₃ separation and recovery.

1. Introduction

Ammonia (NH₃) mainly comes from various industrial emissions, such as in synthetic ammonia plants, melamine tail gas, urea granulating tower tail gas, metallurgical tail gas, and so on. The emission of NH3 into the atmosphere causes serious environmental issues. 1-4 Therefore, the removal and recovery of NH3 from these gases is significant to satisfy

environmental emission regulations and for resource reuse. Recently, ionic liquids (ILs) have attracted considerable attention as environmentally benign solvents for NH3 absorption and recovery due to their peculiar properties, such as negligible vapor pressures, tunable properties and high thermal stability.5-9 Various functionalized ILs, such as hydroxyl ILs, 10-12 metal ILs, 13-16 and protic ILs (PILs) 17,18 were reported for efficient NH3 absorption. For instance, Shang et al. designed a kind of PIL with a strong hydrogen bond donating ability on cations, such as [BIm][Tf₂N] with a high NH₃ absorption capacity of 2.69 mol NH₃ (mol IL)⁻¹ at 313.15 K and 0.10 MPa, along with great selectivity and excellent recyclability. 19 Luo et al. also designed an efficient PIL, [2PyH] [Tf₂N], by varying the cooperative hydrogen bonding, and the NH₃ absorption capacity was high—up to 3.80 mol NH₃ (mol IL)⁻¹ at 303.15 K and 0.10 MPa.¹⁸ In addition, the elucidation of the mechanism of gas absorption is crucial for the design targeted ILs, especially in terms of theoretical perspectives. 20,21

In 2009, Shi et al. published the first work on molecular dynamic (MD) simulations of NH₃ absorption by the IL

[EMIm][Tf2N]. According to the analysis of the interaction and radial distribution function of NH3···cation and NH3...anion, they concluded that the NH3 absorption capacity of [EMIm][Tf2N] is governed by the hydrogen bonding between NH₃ and cations.²² Inspired by their conclusions, a series of promising ILs, such as hydroxyl ILs and PILs, were designed to absorb NH3 efficiently by introducing effective sites that interact with NH₃, and theoretical studies were performed to verify their ideas. For example, Li et al. performed density functional theory (DFT) simulations to confirm that the higher NH₃ absorption capacity of a hydroxyl-functionalized IL than that of the analogous IL without the introduction of a hydroxyl group is mainly due to the hydrogen bonding between the hydroxyl group of the cation and the basic N atom of NH₃. 10 Cai et al. also conducted DFT simulations to verify the mechanism of NH₃ absorption in lithium (Li)-triethylene glycol (TEG)chelated ILs and their results indicated that the high NH3 capacity of ILs is due to the strong interaction between hydroxyl sites of the cation and NH3.23 Similarly, the DFT calculation results of our previous work¹⁹ also indicated that NH₃ absorption of [BIm][Tf₂N] may be mainly affected by the protic hydrogen of the cation. Further, MD simulations were conducted to confirm that NH₃ can compete with [Tf₂N] for interaction with the protic hydrogen of the cation, forming a strong hydrogen bonding.24 So far, theoretical methods have attracted increasing attention to study the mechanism of

Our previous work revealed that PILs not only show impressively high NH3 absorption capacities but also their capacities are considerably affected by anions. 17,19 For instance, the capacities for NH₃ absorption of [BIm][Tf₂N], [BIm][SCN] and [BIm][NO₃] were 2.69, 1.96 and 1.30 mol NH₃ (mol IL)⁻¹ at 313.15 K and 0.10 MPa, respectively, as shown in Table 1. However, the mechanism is not clear. Here, DFT and MD simulations were conducted to further study the NH₃ absorption mechanism by [BIm]⁺-based PILs to reveal the essence of the interaction between ILs and NH3, as well as the effect of anions on NH3 capacity. The comprehensive theoretical studies not only complement understanding on NH3 absorption mechanisms by the PILs but also provide a guideline to design new efficient ILs.

2. Results and discussion

NH₃ absorption with ILs.

2.1 The interaction between NH₃ and [BIm][Tf₂N]

The optimized structures that illustrate [BIm][Tf₂N] interacting with one, two, three and four NH₃ molecules are demonstrated in Fig. 2. The results showed that the NH₃

Fig. 1 Structures of the cation and anions studied in this work.

molecule mainly interacts with the site of protic hydrogen (H-N³, the atom labels are provided in Fig. 1) of [BIm][Tf₂N] via hydrogen bonding. For example, the distance between N of the 1st NH₃ and H of H-N³ was 1.7 Å (Fig. 2a), which is less than the sum of the van der Walls radii of N and H atoms.25 On the other hand, hydrogen bonding was also discovered between NH₃ and the anion [Tf₂N], as shown in Fig. 2a-d. For $[BIm][Tf_2N]\cdots NH_3$, the interaction energy (ΔE) between the PIL and NH₃ was -17.30 kcal mol⁻¹ when the NH₃ was located around H-N³ (Fig. 2a), which is almost twice as those of NH₃ interacting with H-C^{2/4/5} (see Fig. S1†). For [BIm][Tf₂N]···2NH₃, the most stable structure was obtained when the 2nd NH3 molecule connected to the 1st NH3 molecule (see Fig. 2b). The ΔE between the IL and two NH₃ molecules was -27.30 kcal mol⁻¹, implying that the ΔE for the 2nd NH₃ molecule was -10.00 kcal mol⁻¹. Interestingly, the distance between the N atom of the 1st NH3 molecule and H-N³ decreased from 1.7 Å to 1.6 Å while the 2nd NH₃ molecule was absorbed. In other words, the hydrogen bonding formed between the 1st NH₃ molecule and H-N³ was enhanced. A similar phenomenon was discovered from the interactions between H₂O molecules and [EIm][Tf₂N], which means that the distance between the O atom of the 1st H₂O molecule and H-N³ of [EIm]⁺ is shortened when the 2nd H₂O molecule interacts with the 1st H₂O molecule.²⁶

The structures of [BIm][Tf₂N] interacting with three and four NH₃ molecules are demonstrated in Fig. 2c and d, respectively. It was found that the rest of NH₃ molecules can interact with the 1st absorbed NH₃ molecule. It is worth noting that the calculated ΔE of absorption of the 1st and 2nd NH₃ molecules is much larger than that of the 3rd and 4th NH₃ molecules, *i.e.*, -17.30 and -10.00 kcal mol⁻¹ *versus* -4.60 and -5.70 kcal mol⁻¹. The findings revealed that the 1st and 2nd NH₃ molecules are absorbed *via* different types of interactions compared to the 3rd and 4th NH₃ molecules.

of [BIm][Tf₂N] to capture one NH₃. The numbers on the lines indicate

■ ΔE_{nauli}+ΔE_{elstat}

-20 -50 -60

-90 100-

The former two are through strong hydrogen bonding while the latter two are dominated by VdW interactions. The essence of these interactions was further analyzed *via* energy decomposition analysis (EDA), and detailed discussions are given in the next sections.

2.2 Energy decomposition analysis of NH_3 absorption with $[BIm][Tf_2N]$

In order to present a quantitative interpretation and more details of the interactions between [BIm][Tf2N] and NH3, EDA was performed. Within the EDA scheme, the total interaction energy consists of three meaningful physical terms, namely, the repulsive exchange (Pauli) interaction ΔE_{Pauli} , the electrostatic interaction $\Delta E_{\rm elstat}$ and the orbital interaction $\Delta E_{\rm orb}$, which includes the orbital relaxation and orbital mixing between the fragments.27,28 In addition, the summation of Pauli repulsion and electrostatic interactions is often defined as the steric interaction ΔE_{steric} , which arises from the fact that each atom in a molecule occupies a certain amount of space. The total and the individual interactions of the process for each NH₃ absorbed by [BIm][Tf₂N] are given in Table 2 and Fig. 3. The results showed that the interactions between the 1st and 2nd NH3 molecules with [BIm][Tf₂N] are considerable, especially for the 1st NH₃

molecule, and its total interaction energy is as high as –16.79 kcal mol⁻¹. However, the total interaction energies of the 3rd and 4th NH₃ molecules are much lower than those of the 1st and 2nd NH₃ molecules, which are around –3.50 kcal mol⁻¹. The 3rd NH₃ molecule is favored by electrostatic interactions of 8.16 kcal mol⁻¹ compared to the 4th NH₃ molecule. This is most likely because the 3rd NH₃ molecule interacts with the anion through hydrogen bonding (see Fig. 2c).

The plots in Fig. 3 demonstrate that the orbital interaction is more likely to decay than the steric interaction. For example, the orbital interaction decreased by 14.65 kcal mol $^{-1}$ from the 1st to the 2nd NH $_3$ molecule, while the corresponding steric interactions only decreased by 7.00 kcal mol $^{-1}$. The results indicated that the orbital interaction makes a great contribution to the total interaction. However, in the case of the 4th NH $_3$ molecule, the changes of $\Delta E_{\rm steric}$ and $\Delta E_{\rm orb}$ were small compared to those of the 3rd NH $_3$ molecule, which is most likely due to physical interaction of the 4th NH $_3$ molecule. In this case, the electrostatic interaction plays the most important role.

2.3 Gibbs free energy of NH₃ absorption with [BIm][Tf₂N]

Our previous experimental results¹⁶ showed that the NH₃ absorption capacity of [BIm][Tf₂N] is 2.69 mol NH₃ (mol

Table 2 EDA at the M062X/TZP level for each step ([BIm][Tf₂N]···(i-1) NH₃ + NH₃ \rightarrow [BIm][Tf₂N]···iNH₃, i = 1–4) of [BIm][Tf₂N] to capture one NH₃ molecule, and all the energies are expressed in kcal mol⁻¹

$\Delta E_{ m orb}$	-79.05	-64.40	-49.58	-51.54
$\Delta E_{ m total}$	-16.79	-9.14	-3.81	-3.54

^a $\Delta E = E(IL \cdots nNH_3) - E(IL \cdots (n-1)NH_3) - E(NH_3)$.

IL)⁻¹, which is close to 3.0 mol NH₃ (mol IL)⁻¹ at 313.15 K and 0.10 MPa. The high capacity for NH3 of [BIm][Tf2N] was probably attributed to the strong hydrogen bonding site H-N³ in the [BIm]⁺ cation. Here, we revisited this open question by computing the Gibbs free energy (ΔG) for [BIm] [Tf₂N] absorption of different moles of NH₃ molecules. The calculated ΔG values are shown in Fig. 4, and their values are highlighted in red. The ΔG values for [BIm][Tf₂N] absorbing one and two moles NH₃ were -3.6 and -3.1 kcal mol⁻¹, respectively. These two negative values indicated that the process of [BIm][Tf₂N] absorbing one or two moles NH₃ takes place spontaneously and easily.

The ΔG value for [BIm][Tf₂N] absorbing three moles NH₃ was 1.8 kcal mol⁻¹. This slightly positive value reveals that the absorption of three moles NH3 by [BIm][Tf2N] is thermodynamically feasible. Moreover, the other conformers of [BIm][Tf₂N]···3NH₃ are shown in Fig. S3.† The relative energies (E_r) , ΔG values and Boltzmann distribution weighting factors (w_i) are summarized in Table S1.† The results indicated that most of the conformers have comparable E_r values and their ΔG values are close to zero as well. It should be noted that the most stable structure of [BIm][Tf₂N]···3NH₃ (Fig. S3a†) is slightly more stable than the structure in Fig. 2c (equal to Fig. S3d†). The energy of the former was 1.1 kcal mol⁻¹ lower than the latter. Moreover, the most stable structure was dominant among the displayed conformers with a w_i value of 0.432, and its corresponding ΔG value was -0.05 kcal mol⁻¹. The result indicated that [BIm][Tf₂N] is capable of absorbing close to 3 moles NH₃ in consideration of thermodynamics. It is also consistent with the experimental fact that the NH₃ capacity of H-C² is less than 1.0 mol NH_3 (mol IL)⁻¹. 5,6,17

We also calculated the ΔG value for the [BIm][Tf₂N] ···4NH₃ system. The DFT calculations yielded a large positive value of 6.7 kcal mol⁻¹ for the hypothetical process, indicating that [BIm][Tf2N] failed to absorb 4 moles NH3 spontaneously at 313.15 K and 0.10 MPa. Furthermore, the energy of the most stable structure of [BIm][Tf2N]···4NH3 (Fig. S4a†) was 3.8 kcal mol⁻¹ lower than that of the structure shown in Fig. 2d (equal to Fig. S4t†), but the ΔG value of $[BIm][Tf_2N]$ absorbed 4 moles NH_3 molecules based on the

Fig. 4 $\triangle G$ of [Blm][Tf₂N] + iNH₃ \rightarrow [Blm][Tf₂N] $\cdots i$ NH₃, (i = 1-4) calculated at the M062X/def2TZVP level, including the B3LYP/6-31 + G* thermodynamic correction.

most stable structure of [BIm][Tf₂N]···4NH₃ (2.5 kcal mol⁻¹), which indicated that this structure is also unfavorable from a thermodynamic point of view.

2.4 The interaction between anions and NH₂

Based on the above analysis, it was concluded that H-N³ plays an important role in NH₃ absorption of [BIm][Tf₂N]. However, the experimental results (see Table 1) also indicated that the anions have an observable influence on NH₃ capacity of PILs. To reveal the possible mechanisms, the interactions between anions and NH3 were also studied by DFT calculations. As seen in Fig. 5, all the anions interacted with NH3 via hydrogen bonding. The interaction energy between [NO₃] and NH₃ was the largest one among them, while the difference of interaction energies was less than 3.0 kcal mol⁻¹. Although the anion [Tf₂N] offered more hydrogen bond acceptors than the other two anions, it seemed impossible to cause such a great difference in NH3 capacity of PILs (NH3 capacity of [BIm][Tf₂N] is almost twice that of [BIm][NO₃] in Table 1). Furthermore, in terms of interaction energies, [BIm][NO₃] should show a more likely higher NH3 capacity than [BIm][SCN], which conflicts with experimental results. In sum, the interaction between NH3 and anions is not the direct reason that affects NH3 absorption capacity of PILs.

2.5 The interaction between cations and anions

The H-N³ site is a main hydrogen bond donor that interacts with NH3, and then the anions may also provide hydrogen bond acceptors to form hydrogen bonding with the protic site, therefore influencing the NH3 absorption capacity of PILs. In order to verify this assumption, DFT calculations were conducted to study the interactions between cations and anions. The most stable structures for these three "ion pairs" of [BIm][Tf₂N], [BIm][SCN] and [BIm][NO₃] are depicted in Fig. 6. In addition, the interaction energies between cations and anions are indicated as well (the detailed values are in Fig. S10†). It was found that all the anions prefer to interact with H-N³, meaning that the anions compete against NH₃ for H-N³. It was implied that the stronger interaction between cations and anions results in a lower NH3 absorption capacity. As seen in Fig. 6, the interaction

Fig. 5 The optimized structures of NH₃ interact with (a) [Tf₂N]⁻, (b) [SCN] and (c) [NO₃] (color of ligand: N, blue; H, gray; C, dark gray; S, yellow; O, red; F, pale turquoise).

Order of interaction between cation and anion

Fig. 6 The interaction energies between cations and anions of PILs. A more negative value indicates a stronger interaction (color of ligand: N, blue; H, gray; C, dark gray; S, yellow; O, red; F, pale turquoise).

energies between the cations and anions of these PILs followed the order $[BIm][Tf_2N] < [BIm][SCN] < [BIm][NO_3]$. Moreover, the increasing interaction between cations and anions would decrease the free volume in PILs that accommodates NH₃, decreasing the NH₃ capacity of PILs.²⁹ Therefore, the reason for the anions influencing NH₃ capacity of PILs originates from the strength of interaction between anions and cations.

2.6 The distribution of hydrogen bonding around [BIm]⁺

The MD simulations of NH3 absorption of ILs were further carried out to study the distribution of NH3 and anions in PILs. Fig. 7 shows the combined distribution functions of ∠X-H···N(NH₃) versus the distance between the H atom of the cation and the N atom of NH₃ (R_{H···N(NH₃)}). X refers to C

Fig. 7 Combined distribution functions of ∠N/C-H···N(NH₃) versus the distance of H···N(NH₃) between the cation and NH₃. The first column of panels A, F, and H reflects the distribution of NH3 around H-N³. The 2nd to 4th columns of the panels reflect the distribution of NH₃ around H-C², H-C⁴, and H-C⁵, respectively. Panels A-D, E-H and I-L are combined distribution functions for NH₃ absorption by [BIm] [Tf₂N], [BIm][SCN] and [BIm][NO₃], respectively.

(i.e., C2-site, C4-site, and C5-site, indicated as C2, C4, and C⁵, respectively) and N (i.e., N³-site, indicated as N³) atoms on the imidazolium ring of [BIm]+. It was found that NH3 molecules are mainly distributed around H-N3 in [BIm] [Tf₂N] (with a large region in red color, panel A). In panel A, the red region represented the range where $130^{\circ} < \angle N$ - $\text{H} \cdot \cdot \cdot \text{N}(\text{NH}_3) < 180^{\circ} \text{ and } 1.5 \text{ Å} < \text{R}_{\text{H} \cdot \cdot \cdot \cdot \text{N}(\text{NH}_3)} < 2.0 \text{ Å, which}$ indicated that most of the NH3 molecules interact with H-N³ by strong hydrogen bonding. A similar red region was also found in panel E, but its area was much less than that of [BIm][Tf₂N]. It was demonstrated that part of NH₃ molecules distribute around H-N3 in [BIm][SCN] by strong hydrogen bonding. However, it was hard to find any red region in panel I, which means that few NH3 molecules distribute around H-N3 in [BIm][NO3] by strong hydrogen bonding. In addition, regions with red color were also found in panels B-D. These are possible indications that H-C², H-C⁴, and H-C⁵ are sharing part of NH₃ molecules around H-N³.

2.7 The distribution of anions around the [BIm]⁺ cation

To study the distribution of anions around H-N3 of the cation, the radial distribution functions (RDFs) before and after NH₃ absorption of H-N³(cation)···N/C(anion) and the three-dimensional probability distribution of NH3, and the anions around the [BIm]+ cation in PILs after NH3 absorption were calculated as shown in Fig. 8 and 9, respectively. The results showed that the distance of the first evident peak of RDFs for the three PILs follows the order $[BIm][NO_3] < [BIm][SCN] < [BIm][Tf_2N]$. The $[NO_3]$ anions were organized closer, and more [SCN] anions were around H-N³, which leads to a smaller probability for NH₃ molecules interacting with H-N3 in [BIm][NO3] and a lower NH₃ capacity. However, for the [Tf₂N] anion, it was the most far away from H-N3 among the three anions.

Fig. 8 RDF presentation between the H atom of H-N³ in [BIm]⁺ and the central atom in anions (the N atom is assigned as the central atom for [Tf₂N]⁻ and [NO₃]⁻, and the C atom is assigned as the central atom for [SCN]").

Fig. 9 Three-dimensional probability distribution of NH₃ (blue) and anions (yellow) around $\left[BIm\right]^+$ in the bulk liquid of ILs after NH₃ absorption. In each case, the blue and yellow surfaces are drawn at 4 times the average density of the corresponding NH₃ or anions in the bulk region.

Consequently, [BIm][Tf2N] provided more opportunities for H-N³ to attract NH₃ and more free volume to accommodate NH₃. 30,31 Interestingly, the RDFs of [BIm][Tf₂N] before and after NH3 absorption exhibited more evident changes than those of the other two PILs. This is likely because the [Tf₂N] anion has the largest size among these three anions, so it is vulnerable to be attacked by NH3 resulting in considerable spatial displacement. Fig. 8 also shows that the anion [Tf₂N] keeps away from H-N³ in the bulk phase of [BIm][Tf2N] with NH3 absorption compared to the bulk phase without NH3 absorption.

3. Conclusions

In this work, both DFT calculations and MD simulations were conducted to deeply understand the mechanisms of NH₃ absorption with PILs, including [BIm][Tf₂N], [BIm] [SCN] and [BIm][NO₃], in terms of theoretical insights. The interactions between [BIm][Tf2N] and NH3, anions and NH3, cations and anions, and the NH3 distribution around H-N3 and H-C^{2/4/5} in [BIm]⁺, as well as the anion organization around H-N3 before and after NH3 absorption for the three PILs, were systematically investigated. The results indicated that both the strong hydrogen bonding between NH3 and H-N³ of the cation and the weak interaction between cations and anions lead to a high NH3 capacity of the PILs. Moreover, the orbital moiety of the total interaction between NH3 and [BIm][Tf2N] decays dramatically with the increase of NH3 absorption, and the major part changed from orbital to electrostatic, which further proved that 3.0 mol NH₃ (mol IL)⁻¹ is a threshold for the NH₃ capacity of [BIm][Tf2N]. On the other hand, the anions of the PILs could also compete with NH₃ for interaction with H-N³ of the cations, when the interaction between the cations and anions became stronger, the corresponding anions would prefer to gather near or around the H-N3 of the cation and decreased the probability of H-N3 to interact with NH3, thus reducing the NH3 absorption capacity of the PILs. This study provides a deep understanding of the mechanism of NH₃ absorption with ILs, which will guide the design of novel functionalized ILs for NH3 separation and recovery applications.

4. Computational details

4.1 Density functional theory (DFT) calculations

The structures of PILs and PIL-NH3 were first optimized at the B3LYP/6-31 + G* theoretical level in consideration of solvation via polarizable continuum mode (PCM),32 together with the employment of the DFT-D3 approach to consider the interaction of dispersion.³³ Frequency analyses were performed at the same level to confirm the optimized structures: no imaginary frequencies were found for the local minima. Then single point calculations were conducted for optimized structures at the M062X/def2-TZVP level to obtain the energy in the ideal gas phase. The zero point energies (ZPE) were obtained from the frequency calculation at the B3LYP-D3/6-31 + G* level. When applying PCM, the solvent parameters of ILs are necessary. The dielectric constant and refractive index of the ILs studied were estimated to be 15.0 and 1.43, respectively, based on published works. 34-36 All the above calculations were performed by employing the Gaussian09 package.37 The Amsterdam density functional (ADF) suite of programs was employed to perform energy decomposition analysis (EDA).38,39 EDA was conducted via single point calculations at the M062X level with an allelectron basis set of TZP quality.40

The interaction energy (ΔE), which is the change in energy between the complex and its monomers, was calculated using egn (1):

$$\Delta E = E(A \cdots B) - E(A) - E(B) \tag{1}$$

where E(A), E(B) and $E(A \cdots B)$ are the ideal gas phase electronic energies of A, B and $A \cdots B$, respectively.

The final Gibbs energy (G) in solution included two parts, i.e., the ideal gas phase electronic energy (E) and the gas phase thermostatistical contribution (G_{RROH}) (see eqn (2)).

$$G = E + G_{RROH} \tag{2}$$

The change in Gibbs energy (ΔG) for a process can be calculated by eqn (3):

$$\Delta G = \Delta E + \Delta G_{\rm RROH} \tag{3}$$

The thermostatistical contribution is calculated as follows:

$$G_{\text{RROH}} = \text{ZPE} + E_{\text{therm}} + PV - TS$$
 (4)

where ZPE is the zero point vibrational energy, E_{therm} is the thermal energy, and P, V, T, and S denote the pressure, volume, temperature and entropy, respectively. T and P were set to 313.15 K and 0.10 MPa, respectively.

4.2 Molecular dynamic (MD) calculations

All the MD simulations were performed using the GROMACS simulation package41 at 313.15 K and 0.10 MPa. The time step was set to 2 fs and the velocity-Verlet algorithm was used

to integrate the equations of motion. All the covalent bonds were constrained using the LINCS algorithm. A cutoff of 1.2 nm was set for both the LJ and Coulombic interactions. The LJ tail correction was added to the energy and pressure, and long-range electrostatic interactions were calculated using the particle-mesh Ewald (PME) method. Cross interactions between different atom types were computed using standard Lorentz–Berthelot rules. The temperature was controlled using a Nosé–Hoover thermostat with a coupling time constant of 0.2 ps and the pressure was maintained using a Parrinello–Rahman barostat with a coupling time of 2.0 ps. Periodic boundary conditions were applied in all directions.

The initial configurations were built with the PACKMOL package 43 by randomly disposing 1000 ILs for pure IL systems and 1000 ILs + m NH $_3$ (m = 3000, 2000, 1500 for [BIm][Tf $_2$ N], [BIm][SCN] and [BIm][NO $_3$], respectively) molecules. The force field values of the ILs were obtained from the literature, $^{44-47}$ and the NH $_3$ molecule was modelled using the OPLS-AA force field. 48 Due to the low-diffusion of ILs, the system was heated up to 500 K for 10 ns to keep the ion mobility. The temperature was gradually decreased to 313.15 K. The production run of 100 ns was carried out in an NPT ensemble, and structure analysis was conducted based on the last 50 ns.

--------------------------	---------------------

bis(trifluoromethylsulfonyl)imide

[2PyH][Tf₂N] 2-Aminopyridinium

bis(trifluoromethylsulfonyl)imide

[EMIm][Tf₂N] 1-Ethyl-3-methylimidazolium

bis(trifluoromethylsulfonyl)imide

[BMIm][Tf₂N] 1-Butyl-3-methylimidazolium

bis(trifluoromethylsulfonyl)imide

[BMIm][SCN] 1-Butyl-3-methylimidazolium thiocyanide

[BMIm][DCA] 1-Butyl-3-methylimidazolium dicyandiamide

[EIm][Tf₂N] 1-Ethyl-imidazolium

bis(trifluoromethylsulfonyl)imide

Conflicts of interest

The authors declare no conflict of interest.

Acknowledgements

This study was financially supported by the National Key R&D Program of China (2020YFA0710200), the National Natural Science Foundation of China (22122814, 21890764 and 21838010), the Youth Innovation Promotion Association of the Chinese Academy of Sciences (2018064), and the Major Scientific and Technological Innovation Project of Shandong Province of China (2019JZZY010518).
