Acoustic microfluidics for colloidal materials and interface engineering

Xiong Zhao,^{†ab} Zhenzhen Chen,^{†ab} Yinan Qiu^c and Nanjing Hao^{id} *^{ab}

The advent of microfluidic and microfabrication technologies provides vast opportunities for the rational design of colloidal materials and interfaces. However, the development of microscale lab-on-a-chip solutions is greatly limited by the lack of flexible control and intensive process kinetics. The integration of acoustics and microfluidics provides tremendous opportunities to manipulate fluids for the spatiotemporal control of engineering applications. In this perspective, we discuss the utility of acoustic microfluidics as an emerging tool for colloidal materials and interface engineering. We outline the underlying principles involved in acoustic microfluidics, assess the achievements and shortcomings of efforts so far in the field, and then highlight the bottlenecks that hinder the practical implementations of acoustic microfluidics from the viewpoints of both academic and industrial applications. We further provide our perspectives toward future research to develop advanced materials and interface systems using acoustic on-chip devices.

1. Introduction

The advent of microfluidics in the 1990s has led to significant achievements and outstanding performance characteristics that range from colloidal materials development and interface engineering applications.¹ By virtue of its unique merits in terms of ease-of-use, low-cost, portability, scalability, and automation, microfluidics has demonstrated effectiveness and improvements over conventional benchmark methods.^{2–7} Although considerable progress has been achieved, the low Reynolds number at the microscale means that microfluidic devices face the critical challenge of process intensification inside the microchannels, which greatly limits their applicability.^{8–10}

To overcome this problem, researchers have developed many passive strategies that rely on the optimization of channel geometries and device configurations.¹¹ However, these strategies are not only short of flexible control but lack intensive process kinetics within a short-range proximity.^{12,13} Alternatively, active strategies that rely on an external energy supply such as acoustics, optics, magnetism, electrics, and heat have emerged. Among them, acoustics-driven microfluidics presents

attractive features of precise positioning, high tunability, deep penetration, and good biocompatibility, which provide tremendous opportunities to manipulate fluids for the spatiotemporal control of engineering applications.

This perspective review assesses the promise of acoustic microfluidics for colloidal materials and interface engineering (Fig. 1). We outline the principles underlying acoustic actuation, summarize the successes and failures of past efforts, highlight the current bottlenecks hindering practical implementations, and finally provide ideas to inspire future research in this field.

2. Working principles

Conventional microfluidic strategies are largely affected by the strong capillary forces and high surface tension in microscale channels, leading to critical challenges for both colloidal materials development and interface engineering applications. The introduction of acoustics enables microfluidic devices to generate acoustic streaming for manipulating liquid precisely and efficiently with controllable reaction and interaction kinetics, providing promising potential for chemical and biomedical engineering.¹⁴ According to different driving modes, acoustic microfluidics can be classified into two main groups: bulk acoustic wave (BAW) microfluidics and surface acoustic wave (SAW) microfluidics (Fig. 2).

BAW devices function through the propagation of acoustic waves in the direction perpendicular to the surface of the piezoelectric materials (mostly lead zirconate titanate, quartz,

Fig. 1 Acoustic microfluidics for colloidal materials and interface engineering enabled by the functions of mixing, separation, concentration, sorting, trapping, and patterning. Reproduced with permissions from ref. 24, 32, 38, 48 and 50–57, respectively.

and aluminum nitride). BAW microfluidics that usually work under a frequency of several hertz to a few hundred kilohertz can be further divided into microsolid-driven microfluidics and microbubble-driven microfluidics (Fig. 2a). Microsolid-driven microfluidics relies on the oscillation of solid microstructures (mostly triangular objects) inside the microchannels upon acoustic actuation, which can induce a pair of counter-rotating vortices

around each solid object.^{15–17} Such a microstreaming phenomenon enables the facilitation of mass transfer for meeting the specific needs of process intensification at the microscale. The reaction and interaction kinetics regulated by the oscillation amplitude can be adjusted flexibly using the power feature (such as voltage, frequency, and waveform) and microsolid properties (such as the tip angle, number, size, and pattern).¹⁷ Similarly, microbubble-driven microfluidics rely on the oscillation of microbubbles that are formed by trapping air pockets in specially designed microchannels with unique cavities or grooves. The strong liquid circulation around microbubbles that is induced by acoustic streaming enables rapid and significant process intensification. It is noted that the resonant frequencies for actuating the microbubbles are directly related to their sizes, providing enough flexibility in adjusting the performance metrics.

SAW devices function through the propagation of acoustic waves in the direction along the surface of the piezoelectric materials (mostly lithium niobate and lithium tantalate) with patterned interdigital transducers (IDTs). Upon actuation of the IDTs, the generated SAW can radiate into the fluid at the Rayleigh angle (θ_R), giving rise to acoustic streaming. SAW microfluidics, which usually work under a frequency from several hertz to a few hundred megahertz, can be broadly divided further into straight IDTs-driven microfluidics, focused IDTs-driven microfluidics, and slanted IDTs-driven microfluidics (Fig. 2b).¹⁸ Straight IDTs-driven microfluidics rely on equal-length straight metal bars (IDT fingers) that are alternately connected on either end. When placing a droplet or microchannel in the wave-propagation path, the SAW energy can induce a strong disturbance in the liquid for process intensification. The reaction and interaction kinetics can be adjusted flexibly *via* the applied voltage and frequency, size

Fig. 2 Typical configurations of acoustic microfluidic devices. (a) BAW device configurations with microsolid-driven mode (top) and microbubble-driven mode (bottom); and (b) SAW device configurations with straight IDTs-driven mode (top), focused IDTs-driven mode (bottom-left), and slanted IDTs-driven mode (bottom-right).

dimensions and location of droplets/microchannels, as well as the configuration of the IDTs. Compared with straight IDTs-driven microfluidics, focused IDTs-driven microfluidics usually rely on curved concentric fingers to generate a stronger SAW energy for intensifying mass transfer. The process kinetics can be controlled well by adjusting a series of design configurations, such as the focal length, degree of arc, finger width, and number of finger pairs. Comparatively, slanted IDTs-driven microfluidics rely on variation of the finger spacing across the transducer width, which enables broad-band frequency excitation for more flexible operations.^{19,20}

3. Colloidal materials development

By virtue of its unique features, such as rapid reaction kinetics, intensive mixing, high integration, and good flexibility, acoustic microfluidics has already demonstrated great potential for the rational design and controllable synthesis of functional micro-/nanomaterials.²¹ Compared with conventional passive microreactors, acoustics-integrated active microreactors not only enable flexible control but also greatly shorten the mixing distance and simplify the microchannel geometries.²² So far, different kinds of organic materials (such as chitosan,²³ PLGA,²⁴ MXene,^{25,26} MOFs,²⁷ liposomes,²⁴ polyvinyl alcohol,²⁸ and proteins²⁹), inorganic materials (such as Au nanoparticles,²³ Ag nanoparticles,³⁰ ZnO nanorods,^{31,32} and MoS₂ quantum dots³³), as well as their hybrid materials have been created from BAW and SAW microfluidic reactors (Fig. 3).³⁴ For example, in organic systems, MOFs, including HKUST-1 and Fe-MIL-88B, can be synthesized within 5 min *via* a

SAW platform due to fast convective transport.²⁷ PLGA-PEG nanoparticles of 57.4 nm and liposomes of 73.1 nm have been synthesized using a BAW device.²⁴ Uniform protein crystallization with a 60% size difference drop compared with passive mixing has been realized by the SAW device.²⁹ In inorganic systems, ZnO nanorods of 3 μm length and 200 nm diameter were synthesized inside the glass capillary using a BAW platform.³² Ag nanoparticles with a size of 40–90 nm were synthesized *via* a SAW device.³⁰ MoS₂ quantum dots with a size of 8.25 nm and considerably higher yields compared with conventional methods were synthesized using a SAW device.³³ In all, the main effect of acoustic microfluidics, regardless of whether BAW or SAW devices, in the synthesis process is to strongly disturb the flow field and enhance mass transfer. Because of such a process intensification ability, acoustic microfluidics can show a better performance than conventional methods in the synthesis of materials.

In spite of the great achievements that have been made, certain problems remain facing acoustic microfluidics for colloidal materials development. Firstly, compared with conventional microreactors, the flexibility and efficiency of acoustic microreactors have been validated. However, the introduction of acoustics requires the support of affiliated equipment, such as function generators and amplifiers, which will certainly compromise to some extent the portability of microreactor devices. Secondly, the feasibility of acoustic microreactors for the synthesis of organic and inorganic micro-/nanomaterials has been demonstrated. However, systematic investigation of the effect of the reactor operation parameters on the physicochemical properties (such as size, shape, and composition) towards the development of an on-chip material library is still lacking. Thirdly, although numerous

studies have identified acoustics-driven intensive mixing inside microchannels and sessile microdrops, the throughput and yield capacity remain a significant challenge for acoustic microreactors. The flow rates in continuous flow microchannels are usually below tens of microliters per minute, while the volumes of the microdrops are generally less than tens of microliters.

4. Interface engineering applications

The introduction of acoustics endows microfluidics with attractive features in terms of precise positioning, flexible control, intensive interactions, and good biocompatibility, which offer great opportunities for advanced interface engineering applications. Compared with conventional microfluidic chips, acoustic microfluidic devices enable the manipulation of particulate objects in a dynamic, predetermined, and controllable manner through acoustic streaming and an acoustic radiation force. So far, a series of BAW- and SAW-based interface engineering solutions have been developed for robust mixing, separation, concentration, sorting, trapping, patterning, *etc.* (Fig. 4).³⁷

The intrinsic advanced functions make acoustic microfluidics possible for benefiting diverse application fields such as biosensing,^{38,42} nanomedicine,³⁵ drug delivery,³⁹ cell lysis,⁴¹ bioliquefaction,⁴³ enzyme bioassays,⁴⁰ batteries,⁴⁴ tissue engineering,⁴⁵ and cell/spheroid/organoid manipulation^{48,49} (Fig. 5). In spite of its apparent effectiveness, many aspects of acoustic microfluidics in interface engineering applications have still not been explored. Firstly, the engineering applicability of acoustic microfluidics has already been verified with extensive experimental observations. However, considering the complexity of acoustic effects in fluidic environments, the underlying physics and working mechanisms are still not clear enough. Secondly, acoustic microfluidics has successfully demonstrated robust size-based separation and concentration capabilities from nanoscale proteins to microscale cells and milliscale organisms. However, the selective treatment of similar-sized or molecular-sized objects remains an unmet need. Thirdly, due to the actions of acoustic streaming and acoustic radiation forces, acoustic microfluidics can precisely position particulates in a preconceived way at the microscale. Despite the successes achieved at microscopic interfaces, high throughput

manipulation remains a challenging issue. Fourthly, high-power acoustic energy is essential for promoting mixing and facilitating the manipulation of particles and droplets at liquid interfaces. However, significant heat may be produced, which not only affects the sound velocity but also the interface actions, especially for applied biological systems.

5. Technological bottlenecks

As a new technology, there is no doubt that acoustic microfluidics has outperformed the conventional materials development and interface application technologies in many aspects. In particular, acoustics not only enables microfluidics to achieve a better performance than existing approaches but also enables process intensification and flexible control to be performed that were not previously available. During the development of applied acoustic microfluidic technology, several technological bottlenecks have gradually been identified, even though they are not yet widely considered by academic and industrial societies.

The fabrication of acoustic microfluidic devices relies largely on photolithography in a cleanroom environment and mold replication techniques, which not only require skilled personnel and specialized instruments but also need tedious and lab-intensive protocols (*e.g.*, spin-coating, baking, ultraviolet exposure, rinsing, *etc.*). These constraints to some extent limit the production efficiency and lead to rising costs. 3D printing represents an emerging and revolutionary technology for novel microfluidics and lab-on-a-chip applications.⁴⁶ Combined with the portable and versatile 3D printing platform, accelerating the translation of acoustic microfluidics to industrial practice will become possible.

Traditional materials used for BAW and SAW microfluidic devices usually include silicon, glass, lithium niobate, and polydimethylsiloxane. Silicon, glass, and lithium niobate substrates possess high chemical robustness but require complicated and expensive fabrication procedures, while the polydimethylsiloxane

polymer cannot endure high temperatures and pressures and may also suffer from severe swelling upon exposure to organic solvents.⁴⁷ Therefore, it remains imperative to find more robust materials that can meet industrial demands.

The format of acoustic microchips generally consists of a single device coupled with an acoustic signal generation system (including a function generator, amplifier, transducer, *etc.*). Most of the currently developed acoustic microchips only put the focus on the demonstration of a single chip for colloidal materials and interface engineering. Although acoustic microfluidics has the potential for parallelization and automation of procedures for high-throughput processing, its scalability has rarely been examined. In addition, considering limitations in multiple individual instruments for acoustic control and heat generation during acoustic excitation, integrated open-source systems and advanced heat management solutions should be configured for practical implementation.

Acoustic microfluidics is drawing particular interest due to its desirable mixing, separation, concentration, sorting, trapping, and patterning functions. It is noteworthy that acoustic microfluidic devices have already demonstrated substantial efficacy through intensifying the reaction and interaction kinetics in certain chemical and biomedical engineering fields. However, it is noted that the application range of acoustic microfluidics remains limited and the industrialization process has lagged significantly behind the research output. To broaden and accelerate the global use of acoustic microfluidics, the close collaboration of professionals from different disciplines is pivotal and necessary.

6. Future perspectives and conclusions

The past decade has witnessed significant progress in the research and development of acoustic microfluidics. A number

of BAW- and SAW-driven devices have been developed so far for use in the fields of colloidal materials development and interface engineering applications. It can be expected that acoustic microfluidics will merge with a myriad of science/engineering fields that will benefit each other in the future. For example, materials science can grow much faster through acoustic microfluidics as the time for material synthesis can be greatly reduced with the prominent mass transfer; 3D printing provides a straightforward and economic approach to fabricating acoustic microfluidic devices, which will promote scientific research and industrial production; biomaterials derived from acoustic microfluidics offer the fascinating potential for point-of-care biosensing and drug delivery applications. With the fusion of acoustic microfluidics and diversified disciplines, more possibilities will be opened up and a bright future is surely anticipated.

Overall, owing to its unique and superior features, especially in terms of flexible control, precise positioning, and deep penetration, acoustics assists microfluidics in being a versatile tool to advance on-chip research and solve unmet practical needs. However, the successful utilization of acoustic microfluidics in practical materials, biology, electronics, and energy fields is still in its infancy and demands continuous effort from both academic and industrial communities. It is anticipated that with emerging technologies in microfabrication, acoustics in combination with microfluidics will provide unprecedented opportunities for revolutionizing conventional practices and expanding the body of knowledge in the field.
