Recent progress in metal–organic frameworks for the separation of gaseous hydrocarbons

Jing-Hong Li, Jun-Xian Chen, Rui-Biao Lin, and Xiao-Ming Chen*

The separation of gaseous hydrocarbons is involved in many important industrial processes for manufacturing chemicals, polymers, plastics, and fuels, and is performed through cryogenic distillation, which is heavily energy-intensive. Adsorption-based gas separation technology by using adsorbent materials can potentially fulfill a much energy-efficient gas separation. As a new generation of adsorbent materials, metal–organic frameworks (MOFs) have been demonstrated to have great potential in addressing important gas separations of hydrocarbons. In this review, we outline the uniqueness of MOF adsorbents for their separation application for gaseous hydrocarbons. A variety of microporous MOFs have been developed for separating gaseous hydrocarbons, which have been achieved by fine-tuning their pore sizes for high molecular sieving effects and/or immobilizing binding sites on their pore surfaces for their specific recognition of small molecules. Herein, we highlight recent important progress in this very important topic, focusing on the purification of ethylene, propylene, and butadiene.

1. Introduction

Gaseous hydrocarbons involve not only essential fuels for modern society but also are applied as important feedstocks in the chemical industry. Hydrocarbons usually are volatile, invisible, and flammable, and tend to be highly dispersed, easily contain mixtures of low concentration, and thus are difficult to handle. The separation and purification of hydrocarbons are critical industrial chemical processes to produce bulk commodities for fuels, polymers, and plastics. Some of these separation processes are carried out on a very large industrial scale. For example, olefin/paraffin separation produces light olefins of over 200 million tonnes. The huge markets of hydrocarbon products make a large contribution (thousands of billions of US dollars) to the annual revenues of the oil and gas industry. Most of the industrial separations of hydrocarbons traditionally rely on thermal-driven technologies, mainly fractional distillation involving numerous evaporation–condensation cycles, which are a high energy-intensity process. In particular, to separate mixed hydrocarbons of similar volatilities for high purity, relevant industrial processes are operated in complicated facilities and under harsh conditions. For the separation and purification of industrial commodities, it is believed that energy-intensive processes, such as distillation consume 10–15% of the world's energy production. Adsorptive separation based on porous adsorbents is a promising technology to lower relevant separation
energy use. For example, alternative technologies, such as adsorptive separation and/or membrane-based technologies, can be up to 10 times more energy-efficient than the traditional distillation methods, which have not been fully realized. These nonthermal technologies can separate hydrocarbon molecules according to their chemical affinities or sizes rather than differences in boiling points, and thus can be carried out under mild conditions, hence greatly reducing the energy inputs. The core of these candidate technologies is the separation performance of solid porous media or permeable membranes, which are often made of porous materials with nanosized voids and desired internal pore features.

Metal–organic frameworks (MOFs, also known as porous coordination polymers) are an emerging type of crystalline porous solids, which are assembled by metal-containing nodes and organic linkers or struts through coordination bonds to have pore space. MOFs are unique owing to their exceptional porosity, diverse structures, tunable pore size, and ease of functionality. After two decades of intensive practices, MOF materials are well demonstrated for their exceptional capability for pore adjustment and interior modification. Today, about 100 000 of MOFs have been synthesized. MOFs can show ultrahigh porosity with the largest pore surface area of over 7000 m² g⁻¹, and with pore sizes ranging from 3 to 100 Å, the highest thermal stability of over 600 °C, or exceptional chemical stability in concentrated acidic/basic solutions. The high modularity of MOFs enables us to construct their isostructural analogues of different pore sizes/shapes and surfaces (such as functional organic groups, metal open sites, etc.) with the same coordination networks. The key design element for MOFs is thus to functionalize their pore surface with binding sites and/or adjust their pore size/shape for molecular separation. In this context, MOFs have shown great promise that is superior to conventional porous materials (activated carbon and zeolites) in addressing important separations of gaseous hydrocarbons.

For separation processes in physical adsorbents, their separation mechanism can be roughly categorized into either equilibrium or non-equilibrium adsorption. Equilibrium adsorption processes are thermodynamic and are mainly driven by binding affinity differences dominated by those functional sites (i.e., binding sites) through supramolecular interactions. Pore functionalization with strong binding sites can significantly boost such type of separation performance. For non-equilibrium adsorption processes, including kinetic separation and molecular sieving, the separation is achieved by differing the diffusivity, which is highly affected by the pore sizes and flexibility of adsorbents. The kinetic separation can be amplified after narrowing the pores of adsorbents. There are also cases that the separation is achieved by a combination of both thermodynamic and kinetic processes. In addition, there are gas separation processes that are usually performed with the collaboration of framework flexibility and structural transformation, namely, gate-opening or pore opening. Considering all aspects, it is very important to systematically control the pore size, pore surface and even the flexibility of adsorbents.

On the other hand, hydrocarbons are composed of the same elements with different carbon bonds and carbon/hydrogen ratios. Their physical properties and even chemical properties can be very similar (Table 1). The adsorptive separation by differing their molecular shapes or adsorption affinities in physical adsorbents is thus required to perform with high accuracy, which can be achieved by MOFs. For example, compared with the mixture counterpart propane, propylene, as one major petrochemical product, differs by just two hydrogen atoms, and there is around a 5 K difference in their boiling points. It has been demonstrated that MOFs with embedded binding sites (ranging from open metal sites to polar functional groups, such as anionic fluoride, hydroxyl and amino) can effectively separate olefins/paraffins owing to the difference in thermodynamic affinity. Another applicable approach is to adjust the pore sizes of MOFs

Rui-Biao Lin obtained his BSc in Chemistry from Sun Yat-Sen University (SYSU) in 2009. He obtained his PhD in 2014 (SYSU). During 2016–2020, he worked at the University of Texas at San Antonio as a postdoctoral fellow. Since 2021, he has been working as a full professor in SYSU, where he is working on multifunctional porous materials, including metal–organic frameworks and hydrogen-bonded organic frameworks.

Xiao-Ming Chen received his BS (1983) and MS (1986) degrees from Sun Yat-Sen University and PhD from the Chinese University of Hong Kong in 1992. He is an Academician of the Chinese Academy of Sciences, and Academician of The World Academy of Sciences for the advancement of science in developing countries (TWAS). He is a professor in the School of Chemistry at Sun Yat-Sen University and director of the Institute of Green Chemistry and Molecular Engineering. His current research interest includes the design, synthesis, and crystal engineering of functional metal–organic/hybrid materials, including coordination polymers, metal–organic frameworks, and their applications (such as adsorption/separation, catalysis, and electric/magnetic properties).
for size-matching of gas molecules, which is expected to enhance kinetic separation or sieving effect and finally achieve high selectivity. If the pore aperture size of adsorbents is right between the molecular sizes of different gas components, an adsorption cut-off happens along with the inaccessibility of internal pore space to certain gas components, thus leading to molecular sieving. For some MOFs, the adjustment of pore size in MOFs can be done up to a precision level of 0.1 Å. Given that most hydrocarbon gases have their molecular sizes or kinetic diameters between 3 and 5 Å, microporous MOFs with comparable pore sizes have been intensively investigated for separating hydrocarbon mixtures. Usually, MOFs with large pores can show high sorption capacity but low separation selectivity for gas, whereas the ultramicroporous ones can exhibit high selectivity but low sorption capacity (termed sorption capacity versus selectivity trade off). By simultaneously tuning the pore size and incorporating binding sites, the internal pore space of MOFs can integrate molecular shape matching and preferential binding toward the targeted gas molecules, which is expected to address the trade-off for exceptional separation performance. The complicated effects of MOF flexibility for separation of hydrocarbons have also been noted.

By virtue of pore structural and chemical control of MOF materials, namely, tuning pore size, incorporating functional sites, or their combination, significant progress has been made for gaseous hydrocarbon separation. This review focuses on the research progress of MOF materials for separation of gaseous hydrocarbons in about recent five years. In particular, we summarize representative MOF materials with unique pores and functional sites for C₂H₂ and CO₂ separation, C₂H₆/C₃H₆ separation, C₂H₄ and C₂H₆ separation, C₂H₄/C₂H₆ separation, C₃H₆/C₄H₁₀ separation, and purification of butadiene, xylenes and other volatile gaseous hydrocarbons.

2. Pore structure control of MOFs for separating gaseous hydrocarbons

The separation performance of adsorbents towards target molecules can be affected by various factors, mainly dominated by the adsorbent-adsorbate and adsorbate-adsorbate interactions in the pore space. The adsorbent-adsorbate interactions for specific gases can be adjusted by controlling the pore chemistry and pore size of porous materials for optimal binding affinity, whereas adsorbate-adsorbate interactions are dependent on the physical properties of gas molecules including molecular polarity or polarizability, sizes and shapes. Therefore, rationally tuning the pore sizes of MOFs and/or functionalizing their pore surface have been demonstrated as efficient approaches to boost the separation performance for gases. Both adsorbent-adsorbate and
adsorbate–adsorbate intermolecular interactions for larger or heavier molecules with high polarizability are usually superior to those for small, light and non-polar ones, due to more supramolecular interactions (ranging from hydrogen bonding to electrostatic interactions and van der Waals forces). In this section, representative examples of MOFs for hydrocarbon separation were presented according to the sequence of the polarizability and boiling points of various gases (Table 2).

2.1. Methane purification

Natural gas is a cleanest fossil fuel and has been widely used due to its natural abundance and high energy intensity, and is usually contaminated with gas impurities such carbon dioxide (CO$_2$) and nitrogen (N$_2$). The upgrading of natural gas involves the purification of methane (CH$_4$). Coal-bed methane (CBM) is an excellent complement to conventional natural gas; the recovery of CH$_4$ from it can also reduce the emission of the greenhouse gas CH$_4$ from CBM as well as enhance the safety of coal mineral.\textsuperscript{22} 

Ma et al. used an alkyl MOF, Cu$_2$(ATC) (ATC-Cu, H$_2$ATC = 1,3,5,7-adamantane tetracarboxylic acid), as a methane nano-trap that features oppositely adjacent open metal sites (OMSs) and dense alkyl groups for capturing methane molecules.\textsuperscript{23} At 1 bar and 298 K, this MOF exhibits the highest methane uptake capacity (2.90 mmol g$^{-1}$) among reported MOFs, showing a high CH$_4$/N$_2$ selectivity of 9.7 for an equimolar mixture under ambient conditions. ATC-Cu thus shows promising potential for capturing methane from CBM with low content of methane (<30%). Structural and computational modelling indicated that pairs of open Cu sites with a Cu··Cu distance of 4.43 Å between two neighboring Cu paddlewheels afford considerable dual Coulombic interactions and act as strong binding sites for methane molecules. Also, there are cavities with an aliphatic pore space that can serve as the second binding sites for CH$_4$, with an average interaction distance of ca. 3.5 Å.

Yang et al. studied four nickel-based coordination networks with functional sites (–NH$_2$) or varied pore sizes for the separation of CH$_4$/N$_2$, which supports that the pore size and chemical environment of adsorbents play an important role during methane purification.\textsuperscript{24} Among those four MOFs, Ni([ina]$_2$) showed the highest CH$_4$/N$_2$ selectivity (15.8) with an adsorption capacity of 1.82 mmol g$^{-1}$ under ambient conditions. Ni([ina]$_2$) shows good thermal and moisture stability as well, which can be easily scaled up at a low cost.

The influence of humidity on the separation performances of MOFs for CH$_4$ separation has been noticed. Li et al. investigated a series of isostructural MOFs, [Zn$_2$(1,4-NDC)$_2$(DABCO)], [Zn$_2$(1,4-NDC)$_2$(DABCO)], [Ni$_2$(1,4-NDC)$_2$(DABCO)], and [Cu$_2$(1,4-NDC)$_2$(DABCO)] (namely, DMOF-N, DMOF-A$_1$, DMOF-A$_2$, DMOF-A$_3$, respectively, H$_2$1,4-NDC = 1,4-naphthalenedicarboxylic acid, H$_2$DABCO = 9,10-anthracene dicarboxylic acid, and DABCO = 1,4-diazabicyclo[2.2.2]octane), for CH$_4$ purification.\textsuperscript{25} Altering their aromatic moieties and/or metal centers results in varied pore sizes, hydrophobicity and stability. The hydrophobic pore space suppressed the water sorption and enhanced the moisture resistance of those MOFs, which show high CH$_4$ uptakes and CH$_4$/N$_2$ selectivity. Breakthrough experiments for the CH$_4$/N$_2$ mixture under humid conditions indicated that their CH$_4$/N$_2$ separation performance can be retained even under high humidity (40% RH).\textsuperscript{26}

Zhang et al. reported two isoostructural flexible metal-azolate frameworks (abbreviated as MAFs, a subclass of MOFs with azolate ligands\textsuperscript{39}) [Zn$_2$(OH)$_2$(pzdc)(tz)] DMA and [Zn$_2$(OH)$_2$ (pzdc)(atz)] DMA (MAF-91-DMA and MAF-92-DMA, respectively, H$_2$pzdc = 3,5-pyrazoledicarboxylic acid, Htz = 1,2,4-triazole, and Hatz = 3-amino-1,2,4-triazole), which possess quasi-discrete pores with analogous sizes (MAF-91-DMA: 3.6 × 2.4 and 4.0 × 2.1 Å$^2$, and MAF-92-DMA: 3.7 × 1.3 and 4.0 × 2.1 Å$^2$). Due to the stronger intra-framework hydrogen-bonding interaction in MAF-92, there is a higher gating energy than MAF-91. Thus, MAF-92 showed tremendous shrinkage of apertures (1.0 × 0.8 and 2.5 × 1.0 Å$^2$) after guest removal, while those in MAF-91 (3.5 × 2.2 and 4.4 × 2.0 Å$^2$) showed negligible changes (Fig. 1). Single-component gas adsorption revealed that MAF-92 can adsorb a large amount of CO$_2$ (2.1 mmol g$^{-1}$ at 273 K and 1 bar), but completely excludes N$_2$ and CH$_4$. The molecular sieving performance was further confirmed by breakthrough experiments for CO$_2$/N$_2$ and CO$_2$/CH$_4$, giving selectivities of >1500. This work revealed that the controlled gated barrier can be expected to achieve definite and ideal molecular sieve effect. In contrast, the very commonly encountered framework flexibility of MOFs could be an important drawback to size-dependent molecular sieving for separation of similar molecules.

2.2. C$_2$H$_4$ and C$_2$H$_6$ separation

Ethylene (C$_2$H$_4$) is one of the most important chemical raw materials, which is widely used in the production of plastics, rubber, coatings, and other chemical products. It is mainly produced by cracking ethane (C$_2$H$_6$) or naphtha; thus, C$_2$H$_6$ is a major impurity in the raw mixture. However, the separation of C$_2$H$_4$ from the C$_2$H$_4$/C$_2$H$_6$ mixture is highly challenging due to their small molecular size difference (<0.5 Å) and boiling point difference (ca. 15 K). MOFs have been reported to exhibit significant progress in the separation of C$_2$H$_4$/C$_2$H$_6$.\textsuperscript{28–41}

Usually, the introduction of OMSs on the pore surface of MOFs enables preferential adsorption of C$_2$H$_4$ over C$_2$H$_6$.\textsuperscript{28–30,38,41–44} For example, HKUST-1\textsuperscript{28} and M$_2$(dobdc)\textsuperscript{29–31} (M-MOF-74; M = Mg, Mn, Fe, Co, Ni, and Zn) exhibit stronger binding enthalpies for olefins than alkanes due to the metal–π interactions. Altering the charge density of the metal centers can improve the olefin adsorption and selectivity as revealed by M$_2$(dobdc) isomers.\textsuperscript{33} The appropriate aperture combined with OMSs of high density can also significantly improve the bonding affinity for olefins. In 2020, Qian et al. reported two microporous MOFs functionalized with different amounts of carboxylate groups, in which the carboxylate groups not only can adjust the aperture size, but also chelate with copper(i) ions via post-synthetic modification.\textsuperscript{41} Therefore, Cu$_i^{+}$(UiO-66-(COOH)$_2$) exhibits optimal apertures and exposed Cu(i) centers to form a strong binding affinity for C$_2$H$_4$, while suppressing the adsorption of C$_2$H$_6$. Compared with other UiO-66 materials, Cu$_i^{+}$(UiO-66-(COOH)$_2$) showed the highest ideal adsorbed solution

</table>
Molecular sieves can show the maximum C2H4/C2H6 selectivity via molecular size exclusion, though it is quite challenging due to their similar molecular sizes. In 2018, Chen et al. reported a rigid ultramicroporous MOF [Ca(C6O4)(H2O)] (UTSA-280, H2C4O4 = squaric acid) with one-dimensional (1D) pore channels for molecular sieving separation of C2H4/C2H6. UTSA-280, being assembled by calcium oxide chains and square linkers, shows 1D pores with the minimum cross-sectional area of 14.4 Å², which falls precisely between the sizes of C2H4 and C2H6 (13.7 Å² and 15.5 Å², respectively). Therefore, UTSA-280 can adsorb C2H4 with an adsorption capacity of 2.5 mmol g⁻¹ at 298 K and 1 bar while blocking the diffusion of the relatively large C2H6 molecules (Fig. 2). The C2H4/C2H6 selectivity of UTSA-280 was estimated to be over 10,000. The adsorption heat (Qads) of UTSA-280 for C2H4 ranges from 20.5 to 35.0 kJ mol⁻¹, which is lower than those of MOFs with OMSs (40–85 kJ mol⁻¹). Breakthrough experiments confirmed that high purity (99.2%) of C2H4 can be obtained from an equimolar C2H4/C2H6 mixture with a productivity of 1.86 mmol g⁻¹. It is worth noting that UTSA-280 is capable of efficiently capturing C2H4 from a quaternary CH4/C2H4/C2H6/C2H8 mixture (45/25/25/5). Dispersion-corrected density functional theory (DFT-D) calculations and single-crystal X-ray diffraction experiments revealed that C2H4 molecules are adsorbed by UTSA-280 in a linear array with weak C–H…O hydrogen bonding.

In 2018, Ren et al. reported a series of gallate-based MOFs, [M(C6O4)2(H2O)] (termed M-gallates, M = Mg, Ni, and Co), for C2H4/C2H6 separation with high sieving effect. These MOFs contain 3D interconnected zigzag channels and have Brunauer–Emmett–Teller (BET) surfaces of ca. 424 (Ni), 559 (Mg), and 475 (Co) m² g⁻¹. The pore sizes (3.47–3.69 Å) of these MOFs are close to the molecular sizes of C2H4 (3.28 × 4.18 Å) and C2H6 (3.28 × 4.18 × 4.84 Å³). Therefore, M-gallates could highly selectively adsorb C2H4 over C2H6. Among them, Co-gallate displays the highest performance for separation of C2H4/C2H6. The C2H4 uptake capacity of Co-gallate is much higher than that for C2H6 (3.37 mmol g⁻¹ vs. 0.31 mmol g⁻¹), resulting in a high IAST selectivity of 52 at 298 K and 1 bar for an equimolar C2H4/C2H6 mixture. The IAST selectivity of Mg-gallate is about 37.3 for an equimolar C2H4/C2H6 mixture at 298 K and 1 bar. Breakthrough experiments for a 50/50 C2H4/C2H6 mixture further demonstrated the excellent C2H4/C2H6 separation performances of these low-cost M-gallates.

In 2020, Xing et al. reported a phosphate-pillared MOF, [Zn3(az3)(PO4)] (ZnAtzPO4, Hatz = 3-aminoo-1,2,4-triazole), for C2H4/C2H6 separation with high selectivity (12.4 at 298 K and 32.4 at 273 K). Single-component gas adsorption and kinetic studies revealed that ZnAtzPO4 has a higher C2H4 adsorption capacity (1.92 mmol g⁻¹) than for C2H6 (1.04 mmol g⁻¹) at 298 K and 1 bar, as well as a faster adsorption rate for C2H4 compared with C2H6, giving a kinetic selectivity of 36.6. DFT calculations demonstrated that electronegative groups decorated on the narrow pore apertures of ZnAtzPO4 can effectively capture C2H4 and inhibit the diffusion of C2H6, resulting in an...
efficient equilibrium-kinetic \( \text{C}_2\text{H}_4/\text{C}_2\text{H}_6 \) separation. A flexible ultramicroporous MOF, \([\text{Cu}_2(\text{pyz-CH}_3)(\text{pzdc})_2]\) (ZU-901, pyz-\( \text{CH}_3 \) = 2-methylpyrazine, and \( \text{H}_2\text{pzdc} = 2,3\)-pyrazinedicarboxylic acid), with a pore size of \( 3.4 \times 4.2 \text{ Å}^2 \) was recently reported to show a \( \text{C}_2\text{H}_4 \) adsorption–desorption curve in an \( S \) shape with high \( \text{C}_2\text{H}_4 \) working capacity and facile regeneration.\(^{40}\) Single-component sorption experiments showed that ZU-901 can adsorb \( 1.55 \text{ mmol g}^{-1} \) \( \text{C}_2\text{H}_4 \) and much less \( \text{C}_2\text{H}_6 (0.26 \text{ mmol g}^{-1}) \) at 298 K and 1 bar. The adsorption selectivity of ZU-901 calculated for the pressure swing adsorption (PSA) process is 65. The \( Q_{st} \) of ZU-901 for \( \text{C}_2\text{H}_4 \) was calculated to be \( \sim 25 \text{ kJ mol}^{-1} \), which indicates that ZU-901 can be mildly regenerated. The simulated two-bed PSA process revealed that polymer-grade ethylene (ca. 99.5%) can be obtained by ZU-901 with only 1/10 of the energy consumption compared to simulating cryogenic distillation (2.03 kJ mol\(^{-1} \) vs. 21.84 kJ mol\(^{-1} \)).

For \( \text{C}_2\text{H}_4 \)-selective MOF materials, multiple adsorption and desorption cycles are typically required to achieve high-purity ethylene. In contrast, \( \text{C}_2\text{H}_6 \)-selective adsorbents can directly give pure ethylene by one single separation operation, making it simple to operate and more energy efficient. Compared to the \( \text{C}_2\text{H}_4 \) molecule, the \( \text{C}_2\text{H}_6 \) molecule has a slightly larger polarizability and two additional hydrogen atoms. MOFs with OMSs usually interact strongly with \( \text{C}_2\text{H}_4 \) molecules via \( \pi \) complexation, whereas MOFs with relatively less polar sites, usually, can preferentially absorb \( \text{C}_2\text{H}_6 \) over \( \text{C}_2\text{H}_4 \).\(^{46-66}\)

In an earlier study, Gascon \textit{et al.} firstly reported preferential capture of \( \text{C}_2\text{H}_6 \) over \( \text{C}_2\text{H}_4 \) by utilizing the gate-opening effect of ZIF-7 (also known as MAF-3).\(^{58}\) However, the separation efficiency was low due to the lack of active binding sites. In 2015, Zhang \textit{et al.} reported a porous MAF \([\text{Zn}(\text{batz})]\) (MAF-49, \( \text{H}_2\text{batz} = \text{bis}(5\text{-amino-1H-1,2,4-triazol-3-yl})\text{methylene} \)), which shows a high \( \text{C}_2\text{H}_6/\text{C}_2\text{H}_4 \) selectivity of 9 at 316 K.\(^{59}\) In MAF-49, there are quasi-discrete cages functionalized with a high density of electronegative nitrogen atoms on the surface, which are further interconnected by smaller paths into 1D channels (Fig. 3). DFT calculations and crystallographic study indicated that a \( \text{C}_2\text{H}_6 \) molecule confined in the cage can form stronger and more non-classical \( \text{C–H} \ldots \text{N} \) hydrogen bonds or electrostatic interactions through better structural matching with the cage surface of MAF-49 as compared to the \( \text{C}_2\text{H}_4 \) molecule, which is beneficial for capture, or stronger binding of \( \text{C}_2\text{H}_6 \) compared with \( \text{C}_2\text{H}_4 \). MAF-49 showed, for the first time, an exceptional reversed selectivity compared with porous materials including MOFs, which conventionally bind more strongly with \( \text{C}_2\text{H}_4 \) vs. \( \text{C}_2\text{H}_6 \). Breakthrough experiments for the \( \text{C}_2\text{H}_4/\text{C}_2\text{H}_6 (15:1) \) mixture showed that MAF-49 can give highly pure \( \text{C}_2\text{H}_4 \) (99.95%+) within a single breakthrough operation under ambient conditions.

An appropriate combination of pore sites and pore surface can maximize the weak host-guest interactions, thus highly enhancing the performance of MOFs for \( \text{C}_2\text{H}_6/\text{C}_2\text{H}_4 \) separation.
In 2018, Chen et al. reported two isoreticular MOFs, [Cu(Qc)₂] (HQc = quinoline-5-carboxylic acid) and [Cu(ina)₂] (Hina = isonicotinic acid), featuring 1D channels with pore sizes of ~4.1 and ~3.3 Å, respectively, and an array of low-polarity aromatic surfaces with different contact areas on the channels (Fig. 4). Single-component sorption results demonstrated that [Cu(Qc)₂] shows a higher C₂H₆ uptake than C₂H₄ (60.0 cm³ cm⁻³ vs. 25.3 cm³ cm⁻³, i.e., 1.85 mmol g⁻¹ vs. 0.78 mmol g⁻¹) at 298 K and 1 bar, thus giving a high C₂H₆/C₂H₄ selectivity of 3.4 for an equimolar C₂H₆/C₂H₄ mixture at 298 K and 1 bar. In contrast, [Cu(ina)₂] shows comparable adsorption capacity for both gases (C₂H₄: 67.4 cm³ cm⁻³, and C₂H₆: 64.3 cm³ cm⁻³, i.e., 1.99 mmol g⁻¹ vs. 1.90 mmol g⁻¹) due to the smaller polar surface. Neutron powder diffraction and DFT-D calculations showed that the high C₂H₆ selectivity in [Cu(Qc)₂] can be attributed to the more C–H⋯π interactions formed between C₂H₆ and [Cu(Qc)₂]. Breakthrough experiments demonstrated that high purity of C₂H₄ (> 99.9%) can be directly collected from a 50/50 C₂H₆/C₂H₄ mixture by a packed column bed of [Cu(Qc)₂], with a separation productivity of 587 mmol L⁻¹.

The incorporation of the peroxo sites into MOFs can improve the affinity for C₂H₆. In 2018, Chen et al. reported a microporous MOF [Fe₂(O₂)(dobdc)] (dobdc = 2,5-dioxido-1,4-benzenedicarboxylate) decorated with Fe-peroxo sites that exhibits a high C₂H₆ affinity with a large Qₑ of 66.8 kJ mol⁻¹ (Fig. 5). Single-component sorption isotherms showed that [Fe₂(O₂)(dobdc)] can adsorb a large amount of C₂H₆ (74.3 cm³ g⁻¹, 3.32 mmol g⁻¹) at 1 bar and 298 K and the IAST selectivity for 50/50 C₂H₆/C₂H₄ was calculated to be 4.4 under the same conditions. High-resolution neutron powder diffraction showed that C₂D₆ molecules can form strong non-classical C–D⋯O hydrogen bonds with very short D⋯O distances (~2.17 to 2.22 Å). Therefore, [Fe₂(O₂)(dobdc)] exhibits excellent separation performance, yielding polymer-grade C₂H₄ (> 99.99%) from 50/50 C₂H₆/C₂H₄ mixtures in a single breakthrough operation and a productivity of 0.79 mmol g⁻¹. This result further confirms the unique and important role of non-classical C–H⋯O hydrogen bonds in the molecular recognition and selective adsorption of ethane by MOFs.

2.3. C₂H₂/C₂H₄ separation

In the petrochemical industry, the production of C₂H₄ involves trace amounts of acetylene (C₂H₂) impurities (~1%). The removal of these impurities is crucial as even small amounts of acetylene during ethylene polymerization can cause catalyst poisoning and highly affect the production of polyethylene. Extensive research has been conducted on the adsorptive separation of MOFs for C₂H₂/C₂H₄ mixtures. Chen et al. first reported a series of M’MOFs for separation of C₂H₄ from C₂H₂/C₂H₄. However, these M’MOFs show modest selectivity for C₂H₂ over C₂H₄. In 2015, they further reported an amino-functionalized microporous MOF (UTSA-100) with 1D channels (4.3 Å) and small cages (4.0 Å), showing a moderately high C₂H₄ uptake of...
95.6 cm$^3$ g$^{-1}$ (4.27 mmol g$^{-1}$) at 296 K but with a much lower C$_2$H$_4$ uptake (37.2 cm$^3$ g$^{-1}$, 1.66 mmol g$^{-1}$). The calculated IAST selectivity of UTSA-100 for a 1/99 C$_2$H$_2$/C$_2$H$_4$ mixture is 10.7. This work well demonstrates that suitable pore sizes and binding sites can highly improve the separation performance of MOFs for removing trace C$_2$H$_2$ from C$_2$H$_4$.

To obtain materials with high C$_2$H$_2$ adsorption capacity and high selectivity, in 2016, Chen et al. reported a series of SIFSIX MOFs, namely, SIFSIX-1-Cu, SIFSIX-2-Cu, SIFSIX-2-Cu-i, SIFSIX-3-Ni, and SIFSIX-3-Zn, which allow preferential capture of C$_2$H$_2$ from the C$_2$H$_2$/C$_2$H$_4$ mixture with high selectivity and adsorption capacity. These materials possess different pore sizes, which can be systematically fine-tuned by replacing ligands, metal nodes, inorganic anions or framework interpenetration. Among them, SIFSIX-2-Cu-i with a two-fold interpenetrated framework and pore size of 5.2 Å$^2$ (BET surface area...
503 m² g⁻¹) exhibits a high uptake for C₂H₂ (2.1 mmol g⁻¹, i.e., 47 cm³ g⁻¹) at a low pressure of 0.025 bar, indicating its strong binding affinity for C₂H₂ (Fig. 6). The IAST selectivity of SIFSIX-2-Cu-i for C₂H₂/C₂H₄ (1/99) is up to 44.54. SIFIX-2-Cu with a pore size of 8.0 × 8.0 Å² (BET surface area: 1178 m² g⁻¹) shows the highest C₂H₂ uptake of 8.5 mmol g⁻¹ and a moderate IAST selectivity for C₂H₂/C₂H₄ (1/99) of 10.6. Breakthrough experiments demonstrated that all these SIFSIX MOFs can produce polymer-grade C₂H₄ from C₂H₂/C₂H₄ (1/99 or 50/50 mixtures). DFT-D calculations and high-resolution neutron powder diffraction studies revealed that SiF₆²⁻ pillars in the framework can form strong hydrogen-bonding interactions with C₂H₂, resulting in the high selectivity and adsorption capacity for C₂H₂. This work revealed that the combination of optimal pore size and multiple active sites can greatly improve the selectivity and adsorption capacity of the MOFs.

In 2017, Chen et al. reported a 2-fold interpenetrated MOF SIFSIX-14-Cu-i (UTSA-200) with a smaller pore size (3.4 Å) than SIFSIX-2-Cu-i (4.4 Å) and also functional as SiF₆²⁻ sites that can enhance the binding affinity for C₂H₂ (Fig. 7). The pore size of the activated structure (UTSA-200a) ideally falls between the kinetic diameter of C₂H₄ (4.2 Å) and C₂H₂ (3.3 Å), endowing UTSA-200a with a high performance of molecular sieving separation of C₂H₂/C₂H₄. Single component equilibrium adsorption isotherms showed that UTSA-200a exhibits a high low-pressure uptake (58 cm³ cm⁻³) for C₂H₂ at 0.01 bar but a negligible uptake (~0.25 mmol g⁻¹) for C₂H₄ below 0.2 bar, which is significantly lower than the absorption of SIFSIX-2-Cu-i (2.28 mmol g⁻¹). The IAST selectivity for a 1/99 C₂H₂/C₂H₄ mixture of UTSA-200a was calculated to be 6000 at 298 K and 1 bar. High-resolution neutron powder diffraction further revealed that the strong binding affinity of UTSA-200a for the C₂D₂ molecule was achieved by short C–D···F hydrogen-bonding interactions (1.921 Å). Breakthrough experiments revealed that UTSA-200a can efficiently separate C₂H₂ from a 1/99 C₂H₂/C₂H₄ mixture to give an extremely high purity C₂H₄ (99.9999%) with a productivity of 87.5 mmol g⁻¹.

In 2017, Chen et al. reported an ultramicroporous SIFSIX-MOF [Zn(dps)₂(SiF₆)] (UTSA-300, dps = 4,4'-dipyridylsulfide) with small apertures (2.4 × 3.3 Å²) for specific recognition of C₂H₂ from C₂H₄. The desolvated structure UTSA-300a exhibits large affinity toward C₂H₂ with a Q_st of up to 57.6 kJ mol⁻¹ and thus can be selectively gated by C₂H₂. It should be noted that UTSA-300 shows complete size exclusion of C₂H₄, giving IAST selectivity for the equimolar C₂H₂/C₂H₄ mixture up to >10⁴ at 298 K. Breakthrough experiments confirmed its good separation performance for an equimolar C₂H₂/C₂H₄ mixture. Subsequently, an isostructural framework of UTSA-300 [Cu(dps)₂(SiF₆)] (NCU-100 or UTSA-300-Cu) was reported. In contrast to UTSA-300, NCU-100 possesses elongated Cu(II)–F bonds, showing a larger cavity size (3.6 × 4.3 × 4.2 Å³ vs. 3.5 × 3.9 × 4.1 Å³) in the closed-pore phase. Single-component sorption experiments revealed that NCU-100a shows not only higher low-pressure uptake (0.73 mmol g⁻¹ vs. 0.04 mmol g⁻¹) for C₂H₂ at 0.01 bar and 298 K but also a higher total uptake capacity (4.57 mmol g⁻¹ vs. 3.08 mmol g⁻¹) at 298 K and 1 bar, resulting

![Fig. 5](https://example.com/fig5.png) Crystal structures of (a) pristine [Fe₂(dobdc)] and [Fe₂(O₂)(dobdc)] (b) after oxidization and (c) after final C₂D₆-loading. (d) Sorption isotherms of [Fe₂(O₂)(dobdc)] for C₂H₆ and C₂H₄ under ambient conditions. (e) Breakthrough curves of [Fe₂(O₂)(dobdc)] for an equimolar C₂H₂/C₂H₄ mixture under ambient conditions. in an IAST selectivity for 1/99 C₂H₂/C₂H₄ up to 7291 (298 K and 1 bar). This excellent performance for C₂H₂/C₂H₄ separation can also be attributed to the combination of optimal pore size and strong binding sites, as confirmed by DFT calculations and crystallographic studies. Breakthrough experiments confirmed that high purity C₂H₄ (>99.99%) can be obtained from a 1/99 C₂H₂/C₂H₄ mixture with a productivity of 14.9 mmol g⁻¹.

Recently, Zhai et al. synthesized a series of cluster-based MOFs, [M₉(µ₄-TAZ)₆(µ₃-HTAZ)ₓ(µ₃-TAZ)₁₂₋ₓ(A)ₐ] solvent (SNNU-98-M, M = Mn, Co, Ni, and Zn), for the purification of C₂H₂, in which the tetrazolate (TAZ) ligands coordinate with metal centers in tridentate (µ₃-TAZ) and tetradentate (µ₄-TAZ) bridging modes. These MOFs of acs topology show high framework densities and high stabilities, as well as small pore sizes of 9.0 Å.

![Fig. 7](image2.png) **Fig. 7** (a) Crystal structure of UTSA-200. (b) C₂H₂ and C₂H₄ adsorption isotherms of UTSA-200a at 298 K. Adapted from ref. 71 with permission from Wiley-VCH, Copyright 2018.
5.2 Å (Mn), 4.8 Å (Co), 4.8 Å (Ni), and 4.2 Å (Zn), respectively, which are expected to increase the separation selectivity and volumetric storage capacity. Single-component gas adsorption revealed that SNU-98-Mn exhibits the highest volumetric C\(_2\)H\(_2\) uptake (222.9 cm\(^3\) cm\(^{-3}\)) at 298 K and 1 bar, and a high uptake for C\(_2\)H\(_2\) (175.3 cm\(^3\) cm\(^{-3}\)) at 298 K and 0.1 bar, whereas SNU-98-Co shows the highest C\(_2\)H\(_2\)/C\(_2\)H\(_4\) IAST selectivity (2405.7) under room temperature and 1 bar. Column breakthrough experiments revealed that all these materials show good C\(_2\)H\(_2\)/C\(_2\)H\(_4\) separation performance, with SNU-98-Mn displaying a higher C\(_2\)H\(_4\) productivity of 64.6 mmol g\(^{-1}\) from a 1/99 C\(_2\)H\(_2\)/C\(_2\)H\(_4\) mixture and a longer breakthrough retention time (1362 min g\(^{-1}\) and 701 min g\(^{-1}\) at 273 K and 298 K, respectively, with a gas flow rate of 2 mL min\(^{-1}\)).

The separation of C\(_2\)H\(_4\) from multicomponent mixtures in one step is significant for obtaining polymer-grade C\(_2\)H\(_4\) due to the presence of multiple impurities in the cracking gas. Recently, more MOFs have been revealed to be capable of such multi-component separation.\(^{79-94}\) In 2018, Lu \textit{et al.} reported the highly selective adsorption of C\(_2\)H\(_4\) from a C\(_2\)H\(_2\)/C\(_2\)H\(_4\)/C\(_2\)H\(_6\) mixture by a stable MOF, (Me\(_2\)NH\(_2\)\)[Co\(_3\)(DCPN)\(_2\)(H\(_2\)O)]11H\(_2\)O (TJT-100, DCPN = 5-(3\(^{0}\),5\(^{0}\)-dicarboxylphenyl)nicotinate).\(^{79}\) TJT-100 exhibits a 1D channel (pore size: ~8.0 Å) decorated with a high density of carboxylate oxygen atoms. Single-component adsorption showed that the adsorption capacities of TJT-100 for C\(_2\)H\(_2\), C\(_2\)H\(_4\), and C\(_2\)H\(_6\) were 127.7 cm\(^3\) g\(^{-1}\), 98.1 cm\(^3\) g\(^{-1}\), and 105.4 cm\(^3\) g\(^{-1}\), respectively. The breakthrough experimental results of TJT-100 for the C\(_2\)H\(_2\)/C\(_2\)H\(_4\)/C\(_2\)H\(_6\) mixture (0.5:99:0.5) confirmed the preferential capture of C\(_2\)H\(_2\) and C\(_2\)H\(_6\), giving C\(_2\)H\(_4\) with an excellent purity of 99.997%. DFT calculations revealed that C\(_2\)H\(_2\) and C\(_2\)H\(_4\) have multiple electrostatic interactions with the framework, which facilitates preferential adsorption of C\(_2\)H\(_2\) and C\(_2\)H\(_4\) by TJT-100.

In 2019, Zaworotko \textit{et al.} reported a synergistic sorbent separation technique (SSST), which enables the one-step production of polymer-grade C\(_2\)H\(_4\) from a ternary (C\(_2\)H\(_2\)/C\(_2\)H\(_4\)/C\(_2\)H\(_6\)) gas mixture, and even a quaternary (CO\(_2\)/C\(_2\)H\(_2\)/C\(_2\)H\(_4\)/C\(_2\)H\(_6\)) gas mixture (Fig. 8).\(^{80}\) Three microporous MOFs, TIFSIX-2-Cu-i, SIFSIX-3-Ni, and Zn-atz-ipa, were placed in tandem on the sorbent bed, offering selective adsorption of C\(_2\)H\(_2\), CO\(_2\), and C\(_2\)H\(_6\), respectively. Notably, Zn-atz-ipa shows a rare, higher uptake of C\(_2\)H\(_6\) than CO\(_2\), C\(_2\)H\(_2\), and C\(_2\)H\(_4\) at 0 to 0.4 bar. Breakthrough experiments showed that the packing order of the three MOFs in the sorbent bed has a significant impact on the separation performance, whereas the particle size and amount of the adsorbent have a minor effect. When the packing order is SIFSIX-3-Ni@Zn-atz-ipa@TIFSIX-2-Cu-i, high purity C\(_2\)H\(_4\) can be gained from a 1/49.5/49.5 C\(_2\)H\(_2\)/C\(_2\)H\(_4\)/C\(_2\)H\(_6\) or 1/33/33/33 C\(_2\)H\(_2\)/C\(_2\)H\(_4\)/C\(_2\)H\(_6\)/CO\(_2\) mixture and the working capacities are 0.32 and 0.10 mmol g\(^{-1}\), respectively. This work provides a new path for selective separation of a specific component molecule from a multicomponent gas mixture.

### 2.4. C\(_2\)H\(_2\) and CO\(_2\) separation

Acetylene (C\(_2\)H\(_2\)) is an important chemical raw material that is mainly produced by thermal cracking of hydrocarbons or the

**Fig. 8** (a) SSST involves an adsorption bed with three task-specific physisorbents to purify the commodity (red) with specific binding sites for each trace impurity (blue, green, and yellow). (b) and (c) Experimental column breakthrough curves for C\(_2\)H\(_2\)/C\(_2\)H\(_4\)/C\(_2\)H\(_6\) separation (1:1:1 mixture) on TIFSIX-2-Cu-i and Zn-atz-ipa at 298 K and 1 bar. Breakthrough experiments were conducted in a column (inner diameter, 8 mm) at a flow rate of 2.1 ml min\(^{-1}\). (d) Experimental column breakthrough curves for C\(_2\)H\(_2\)/C\(_2\)H\(_4\)/C\(_2\)H\(_6\) separation (1:1:1 mixture) on a tandem-packed column of TIFSIX-2-Cu-i (~250 mg) and Zn-atz-ipa (~600 mg) at 298 K and 1 bar. Reprinted with permission from ref. 80. Copyright 2019 the American Association for the Advancement of Science.
partial combustion of methane. The resulting gas stream contains various impurities, with carbon dioxide (CO$_2$) being the major one. Thus, the separation of C$_2$H$_2$ from CO$_2$/C$_2$H$_4$ mixtures is important in industry. Although CO$_2$ and C$_2$H$_2$ have similar sizes (CO$_2$: 3.18 × 3.33 × 5.36 Å$^3$, and C$_2$H$_4$: 3.32 × 3.34 × 5.7 Å$^3$) and physical properties (boiling point of CO$_2$ = 194.7 K and of C$_2$H$_2$ = 189.3 K), the opposite quadrupole moments and slightly discrepant polarizabilities between C$_2$H$_2$ and CO$_2$, as well as the stronger π-bonding ability with metal sites and hydrogen-bonding donor ability of C$_2$H$_2$, allow the realization of their separation by means of rational design of pore surfaces and flexible framework amplification.

In the early studies, Kitagawa et al. reported that a microporous MOF material, Cu$_2$(pzdc)$_2$(pyz), with non-coordinated oxygen atoms on the pore surface forms strong hydrogen-bonding interactions with C$_2$H$_2$, showing high C$_2$H$_2$/CO$_2$ separation potential. 100–108 This study firstly demonstrates the effective role of Lewis base sites in enhancing the affinity of a MOF for C$_2$H$_2$. In addition, MOFs with high density of OMSs can facilitate the recognition of acetylene. 100–108 In 2016, Chen et al. reported a MOF-74 isomer, namely, UTSA-74, which has two different (octahedral and tetrahedral) metal coordination geometries along the 1D channel. 101 Each octahedrally coordinated metal ion provides two OMSs upon removal of the coordinated water molecules, leading to enhanced C$_2$H$_2$/CO$_2$ separation. The single-component adsorption isotherms showed that UTSA-74 has a comparable C$_2$H$_2$ uptake capacity (145 cm$^3$ cm$^{-3}$) to Zn-MOF-74 but a smaller CO$_2$ uptake capacity (90 cm$^3$ cm$^{-3}$ vs. 146 cm$^3$ cm$^{-3}$), resulting in UTSA-74 with a good C$_2$H$_2$/CO$_2$ separation performance. This result can be attributed to that each open Zn site can bind with two C$_2$H$_2$ molecules, whereas two oxygen atoms of a CO$_2$ molecule occupy two adjacent OMSs, as demonstrated by the single-crystal X-ray structures and molecular modeling studies. Breakthrough experiments for a 50/50 C$_2$H$_2$/CO$_2$ mixture further demonstrate its good practical separation performance. This is also the first example of using breakthrough experiments to demonstrate the separation performance of MOFs for the C$_2$H$_2$/CO$_2$ mixture.

Based on copper(i)-alkynyl chemistry, anchoring Cu(i) on the surface of a MOF can significantly improve its specific recognition for C$_2$H$_2$. Qian et al. reported a Cu(i)-modified porous MOF, Cu[i][UiO-66-(COOH)]$_2$, which exhibits significantly enhanced C$_2$H$_2$/CO$_2$ separation performance with a high C$_2$H$_2$/CO$_2$ IAST selectivity of 185, compared to the prototype UiO-66-(COOH). 107 The strong π-complexation between the π electrons on C$_2$H$_2$ and Cu ions enables Cu[i][UiO-66-(COOH)]$_2$ to adsorb a large amount of C$_2$H$_2$ (0.9 mmol g$^{-1}$) at low pressure (0.01 bar) and exhibit a high Q$_st$ of 74.5 kJ mol$^{-1}$. Breakthrough experiments demonstrated its highly efficient separation performance for C$_2$H$_2$/CO$_2$. In addition, optimal distribution of OMSs on the pore surface of MOFs can achieve the maximum utilization of these sites. Recently, Li et al. reported a microporous MOF (JNU-4) with high-density OMSs. 108 These sites consist of square-planar copper centers separated by organic ligands, allowing each metal center to effectively bind with C$_2$H$_2$; thus, JNU-4 achieves a high C$_2$H$_2$ adsorption capacity (222 cm$^3$ g$^{-1}$, 9.91 mmol g$^{-1}$) and a moderate IAST selectivity of 8.2 for an equimolar C$_2$H$_2$/CO$_2$ mixture. Notably, this material absorbs C$_2$H$_2$ up to 200 cm$^3$ g$^{-1}$ (8.93 mmol g$^{-1}$) at 298 K and 0.5 bar, but demonstrates a low Q$_st$ of 26.8 kJ mol$^{-1}$. Grand Canonical Monte Carlo (GCMC) simulations demonstrated that C$_2$H$_2$ molecules can bind on both sides of OMSs, while CO$_2$ molecules can only bind on one side. Breakthrough experiments revealed that it has a high C$_2$H$_2$ absorption capacity (160 cm$^3$ g$^{-1}$, 7.14 mmol g$^{-1}$) from an equimolar C$_2$H$_2$/CO$_2$ mixture and can provide fuel-grade C$_2$H$_2$ gas.

Although a high density of OMSs can improve the selectivity for C$_2$H$_2$, electrostatic interactions between CO$_2$ and metal also exist simultaneously. 109–111 This requires a rational distribution of metal sites or the combination of multiple functions such as the pore size and shape to achieve a better C$_2$H$_2$ selectivity. 100,105,112 However, OMSs of high density may result in a high Q$_st$, thus leading to an increase of the energy consumption for adsorbent regeneration. In addition to OMSs, the introduction of functional groups (–NH$_2$, –F, –Cl, –Br, –CF$_3$, etc.) on organic ligands is also an effective strategy to promote selective adsorption of C$_2$H$_2$. 113–116 In 2021, Zhao et al. reported that an amine-functionalized flexible MOF (CPL-1-NH$_2$) with a 1D channel (3.8 × 4.4 Å$^2$) exhibits a high IAST selectivity of 119 for a 50/50 C$_2$H$_2$/CO$_2$ mixture at 298 K and 1 bar. 114 Theoretical calculations showed that the high selectivity of CPL-1-NH$_2$ for C$_2$H$_2$ can be attributed to the NH$_2$ functionalization that enhances C$_2$H$_2$ interaction with the framework, but blocks the stronger interaction between the non-coordinated oxygen atoms and CO$_2$ molecules by occupying the adsorption site of CO$_2$. In the same year, Qian et al. reported an Al-MOF (CAU-10-H) with a pore size of 4.7 Å, exhibiting a high C$_2$H$_2$ storage density (392 g L$^{-1}$) and a separation factor (3.4). 115 GCMC simulations showed that the suitable pore size not only enhances the interaction of C$_2$H$_2$ with high density oxygen atoms and aromatic rings on the pore surface, but also enables synergistic interaction between adjacent C$_2$H$_2$ molecules. Subsequently, CAU-10-H was functionalized with amine to furnish a new MOF (CAU-10-NH$_2$). 116 The later study showed that the amine groups can improve the uptake capacity of C$_2$H$_2$ at low pressure, and significantly enhance the stacking density (0.46 cm$^3$ g$^{-1}$) and C$_2$H$_2$/CO$_2$ selectivity (10.8) compared with the prototype MOF. In addition, these materials have the advantages of high stability, low Q$_st$, easy scale-up, and low cost.

It is well known that pore size and shape play an important role in the separation process, as an appropriate pore size can enhance the strength of interactions between the pore surface and adsorbate, as well as among adsorbates themselves. 97,100,112,117–123 MOFs can be designed and modified to alter the pore sizes, even at the sub-nanometer scale, through substitutions of metal ions, organic ligands, or inorganic anions. Strategies such as building self-interpenetrated networks and pore space partition (PSP) can also be used for the pore size or space modulation. 13,124 In 2019, Chen et al. reported a PSP approach for highly efficient C$_2$H$_2$/CO$_2$ separation. The new porous MOF (FJU-90) was synthesized by inserting a triangular ligand (2,4,6-tris(4-pyridyl)pyridine) into the cylindrical channel of prototype FJU-88. 122 The 1D channel of FJU-88 was separated into a number of aperture cavities with the aperture size decreasing from 12.0 × 9.4 to 5.4 × 5.1 Å$^2$.

Thus, the combination of optimized pore space and oxygen atom sites endows FJU-90a with a high C\textsubscript{2}H\textsubscript{2} adsorption capacity (180 cm\textsuperscript{3} g\textsuperscript{-1}, 8.04 mmol g\textsuperscript{-1}). The separation performance of the activated MOF (FJU-90a) for a 50/50 C\textsubscript{2}H\textsubscript{2}/CO\textsubscript{2} mixture was further confirmed by breakthrough experiments with a productivity of 1.87 mol kg\textsuperscript{-1}.

In 2017, Chen et al. reported a SIFSIX-MOF UTSA-300 that exhibits not only efficient separation of C\textsubscript{2}H\textsubscript{2}/C\textsubscript{2}H\textsubscript{4} but also a high selective uptake for C\textsubscript{2}H\textsubscript{2} from the C\textsubscript{2}H\textsubscript{2}/CO\textsubscript{2} mixture.\textsuperscript{72} Single-component adsorption isotherms revealed that the activated MOF (UTSA-300a) shows a high capacity for C\textsubscript{2}H\textsubscript{2} (68.9 cm\textsuperscript{3} g\textsuperscript{-1}, 3.08 mmol g\textsuperscript{-1}) but adsorbs negligible CO\textsubscript{2} (3.25 cm\textsuperscript{3} g\textsuperscript{-1}, 0.14 mmol g\textsuperscript{-1}) at 298 K and 1 bar, resulting in a high IAST C\textsubscript{2}H\textsubscript{2}/CO\textsubscript{2} selectivity of 743 (298 K and 1 bar) (Fig. 9). Due to the strong C–H···F interactions formed between C\textsubscript{2}H\textsubscript{2} molecules and SIF\textsubscript{6}\textsuperscript{2−}, C\textsubscript{2}H\textsubscript{2} can easily diffuse into UTSA-300a, while CO\textsubscript{2} is restricted because of electrostatic repulsion, as confirmed by DFT calculations and neutron powder diffraction studies. The separation performance of UTSA-300a for a 50/50 C\textsubscript{2}H\textsubscript{2}/CO\textsubscript{2} mixture was further demonstrated by breakthrough experiment in a packed column bed of UTSA-300a. Subsequently, systematic fine-tuning of the pore size of UTSA-300 was performed by replacing the fluoride anionic linkers and metal ions.\textsuperscript{125} Three new SIFSIX-type MOFs, namely SIFSIX-dps-Cu (NCU-100), GeFSIX-dps-Cu, and NbOFFIVE-dps-Cu, were reported to exhibit different pore sizes (1.4 × 3.0 Å\textsuperscript{2}, 1.5 × 3.0 Å\textsuperscript{2}, and 2.2 × 2.7 Å\textsuperscript{2}, respectively) and interlayer distances (4.10 Å, 4.06 Å, and 3.69 Å, respectively). Single-component adsorption isotherms indicated that SIFSIX-dps-Cu shows the highest C\textsubscript{2}H\textsubscript{2} uptake (4.57 mmol g\textsuperscript{-1}) with a high IAST C\textsubscript{2}H\textsubscript{2}/CO\textsubscript{2} selectivity up to 1787 at 298 K and 1 bar. In addition, the gate-opening pressure of SIFSIX-dps-Cu for C\textsubscript{2}H\textsubscript{2} is 0.035 bar, which is lower than those of GeFSIX-dps-Cu (0.05 bar), NbOFFIVE-dps-Cu (0.3 bar), and UTSA-300 (0.06 bar), probably because of its larger interlayer distance. DFT and grand canonical Monte Carlo simulations further revealed that C\textsubscript{2}H\textsubscript{2} molecules have multiple host–guest interactions (H···F hydrogen-bonding interactions) in both inter- and intra-layer cavities. Breakthrough experiments confirmed that high purity C\textsubscript{2}H\textsubscript{2} (≥99.9%) can be obtained from C\textsubscript{2}H\textsubscript{2}/CO\textsubscript{2} (50/50) with a high productivity of 2.48 mmol g\textsuperscript{-1}.

A suitable pore size combined with active sites and a flexible structure can greatly improve the adsorption capacity of a material for C\textsubscript{2}H\textsubscript{2}.\textsuperscript{95,106,114,125–127} Recently, Hong et al. reported that a flexible MOF, namely, [Ni(DTBDA)(MeOH)\textsubscript{2}(DMA)(H\textsubscript{2}O)\textsubscript{2}] (FJI-H36, DTBDA = 3′,5′-di(1H-1,2,4-triazol-1-yl)-[1,1′-biphenyl]-3,5-dicarboxylic acid), with adaptive channels shows efficient adsorption of C\textsubscript{2}H\textsubscript{2}.\textsuperscript{127} FJI-H36 contains two types of cavities with the size of 12.9 × 12.9 Å\textsuperscript{2} and 8.4 × 10.2 Å\textsuperscript{2}, respectively, as well as high-density active sites of open Ni\textsuperscript{II} (4.52 mol L\textsuperscript{-1}) and

free N atoms (9.04 mol L\(^{-1}\)). Single-component sorption experiments confirmed that FJI-H36 shows a high C\(_2\)H\(_2\) uptake of 159.9 cm\(^3\) cm\(^{-3}\) at 298 K and 1 bar, and an ultra-high C\(_2\)H\(_2\) storage density of 561 g L\(^{-1}\). Breakthrough experiments for a 50/50 C\(_2\)H\(_2\)/CO\(_2\) mixture further demonstrated its high adsorption capacity for C\(_2\)H\(_2\) (3.82 mmol g\(^{-1}\)). The structure of FJI-H36 adaptively changes with the adsorption of C\(_2\)H\(_2\), leading to a dense packing of C\(_2\)H\(_2\) in it, as demonstrated by the X-ray crystal structure of C\(_2\)H\(_2\)@FJI-H36.

Recently, Wang et al. reported a sulfate-pillared MOF [Zn(tepb)(SO\(_4\))] (SOFOUR-TEPE-Zn, TEPB = tetra(4-pyridyl)benzene), which possesses dense electronegative pore surfaces to highly promote the separation of C\(_2\)H\(_2\)/CO\(_2\) (Fig. 10). SOFOUR-TEPE-Zn is an isostructural framework with SOFOUR-1-Zn, but with more electron-rich pore surfaces due to the higher electronegative ethylene groups in the TEPB ligand in contrast to the phenyl ring in the TEPB ligand. Single-component sorption results of SOFOUR-TEPE-Zn revealed a higher C\(_2\)H\(_2\) uptake (89.1 cm\(^3\) g\(^{-1}\), 3.98 mmol g\(^{-1}\)) than SOFOUR-1-Zn (69.4 cm\(^3\) g\(^{-1}\), 3.10 mmol g\(^{-1}\)) at 1 bar and 298 K, but a much lower CO\(_2\) uptake (14.1 cm\(^3\) g\(^{-1}\), 0.63 mmol g\(^{-1}\)), resulting in a very high IAST selectivity of 16833 for 50/50 C\(_2\)H\(_2\)/CO\(_2\). Breakthrough experiments for 50/50 C\(_2\)H\(_2\)/CO\(_2\) of SOFOUR-TEPE-Zn give a productivity of 60.1 cm\(^3\) g\(^{-1}\) (2.68 mmol g\(^{-1}\)) of 99.5% purity or 33.2 cm\(^3\) g\(^{-1}\) (1.48 mmol g\(^{-1}\)) of 99.99% purity in its desorption process by stepped helium purging and mild heating. Moreover, SOFOUR-TEPE-Zn also maintains a high C\(_2\)H\(_2\) productivity of 75.5 cm\(^3\) g\(^{-1}\) (3.37 mmol g\(^{-1}\)) of 99.5% purity with 99.82% C\(_2\)H\(_2\) recovery in the simulated pressure swing adsorption processes. DFT-D and GCMC simulation studies revealed that the preferential binding of C\(_2\)H\(_2\) in SOFOUR-TEPE-Zn can be mainly attributed to electron-rich pore surfaces, providing multiple optimal adsorption sites for C\(_2\)H\(_2\).

CO\(_2\)-selective adsorbents can yield high purity C\(_2\)H\(_2\) in one step rather than multiple adsorption–desorption steps, making the operation simple and more energy efficient. Currently, only a limited number of CO\(_2\)-selective MOF materials have been reported, manifesting the challenge in the design of CO\(_2\)-selective materials. Fortunately, several strategies have been reported to promote the selective adsorption of CO\(_2\) in MOFs. For example, Chen et al. introduced hydroxyl functional groups into MOF frameworks, enabling selective capture of CO\(_2\) from C\(_2\)H\(_2\), with a high IAST selectivity of 118.7 for CO\(_2\)/C\(_2\)H\(_2\) (1:2, v:v) at 0.1 bar and ambient temperature. In 2021, Chen et al. reported an ultramicroporous MOF [Cu(F-pymo)\(_2\)]\(_{1.25}\)H\(_2\)O (Cu-F-pymo, F-pymo = 5-fluoropyrimidin-2-olate) with zeolitic gismondine (GIS) topology exhibiting a high selective adsorption of CO\(_2\) over C\(_2\)H\(_2\), which depends on activation temperature (Fig. 11). Cu-F-pymo contains two distinct pore environments, namely, spherical cavities and 1D helical channels, both of which are occupied by removable water molecules. Single-component adsorption isotherms revealed that partially dehydrated Cu-F-pymo can adsorb 1.19 mmol g\(^{-1}\) C\(_4\)H\(_6\).

**Fig. 10** (a) and (b) The building blocks of SOFOUR-TEPE-Zn and electrostatic surface potential. (c) C\(_2\)H\(_2\) and CO\(_2\) adsorption isotherms for SOFOUR-1-Zn and SOFOUR-TEPE-Zn at 298 K. (d) Breakthrough curves of SOFOUR-TEPE-Zn for C\(_2\)H\(_2\)/CO\(_2\) (50/50, v:v) at different flow rates at 298 K. Reprinted with permission from ref. 97. Copyright 2023 Wiley-VCH.
and show negligible C$_2$H$_2$ uptake (0.1 mmol g$^{-1}$) at 298 K and 1 bar. Breakthrough experiments revealed that highly pure acetylene (>99.9%) can be obtained directly from a 50/50 CO$_2$/C$_2$H$_2$ mixture by a single separation operation. Modeling studies demonstrated that CO$_2$ can be preferentially adsorbed in the 1D channels, while C$_2$H$_2$ primarily occupies the spherical cavities. Therefore, the remaining water molecules in the spherical cavities blocked the preferential site, leading to the molecular sieving effect of Cu-F-pymo for CO$_2$/C$_2$H$_2$.

Besides size-matching between gas molecules and the pore structure, reasonable charge distribution would also facilitate the selective recognition of CO$_2$ over C$_2$H$_2$. Chen et al. reported an ultramicroporous porous material Cd[Fe(CN)$_5$NO] (Cd-NP) that exhibits stronger affinity for CO$_2$ in contrast to C$_2$H$_2$. Cd-NP contains quasi-discrete ellipsoidal cavities (6.1 × 4.5 × 4.5 Å$^3$) connected by small apertures (3.2 Å), and its BET surface area is 305 m$^2$ g$^{-1}$ (Fig. 12). 144 Thanks to suitable pore sizes and electrostatic distribution on pore surfaces, Cd-NP shows a high CO$_2$ uptake of 58.0 cm$^3$ g$^{-1}$ (2.59 mmol g$^{-1}$) but a lower C$_2$H$_2$ uptake of 9.7 cm$^3$ g$^{-1}$ (0.43 mmol g$^{-1}$) at 1 bar and 298 K, thus showing a high IAST selectivity (85) for an equimolar CO$_2$/C$_2$H$_2$ mixture. The $Q_m$ of CO$_2$ was calculated to be 27.7 kJ mol$^{-1}$, which would facilitate regeneration of the material under mild conditions. The breakthrough process showed that Cd-NP was capable of producing a high purity C$_2$H$_2$ (99.99%) directly from 50/50 CO$_2$/C$_2$H$_2$ with a productivity of 2.34 mol L$^{-1}$, GCMC simulations and neutron powder diffraction experiments showed that the preferential adsorption of CO$_2$ in Cd-NP can be attributed to the confinement effect of the pore cavity and electrostatically complementary pore surface.

CO$_2$/C$_2$H$_2$ inverse separation can also be achieved using synergistic effects of thermodynamics and kinetics. Li et al. reported an ultramicroporous MOF, Y-bptc, to achieve one-step C$_2$H$_2$ purification from a CO$_2$/C$_2$H$_2$ mixture. Y-bptc processes small windows (4.2 Å) interconnected with large cubic cages with ftw topology. Equilibrium and kinetic adsorption studies revealed that Y-bptc absorbs 55 cm$^3$ g$^{-1}$ (2.45 mmol g$^{-1}$) CO$_2$ and a lower C$_2$H$_2$ uptake at 298 K and 1 bar with an IAST selectivity of 4.1 for 50/50 CO$_2$/C$_2$H$_2$. 136 Moreover, CO$_2$ diffuses faster than C$_2$H$_2$ in Y-bptc, and the calculated kinetic separation coefficient reaches 114 at 298 K. Breakthrough experiments confirmed that CO$_2$ in a 1:1 CO$_2$/C$_2$H$_2$ mixture can be readily removed by Y-bptc, giving C$_2$H$_2$ with a purity of >99% and productivity of 1.52 mmol g$^{-1}$ in a one-step separation process. GCMC simulations further revealed the high affinity of Y-bptc for CO$_2$ resulting from the formation of hydrogen-bonding interactions between $\mu_3$-OH$^-$ groups of the framework and CO$_2$ molecules.

In 2023, Wade et al. reported two isostructural MOFs [Zn$_5$Cl$_4$(bbta)$_3$] (MUF-4, bbta$^{2-}$ = benzo-1,2,4,5-bistriazolate) and MUF-4-F, which exhibited completely opposite adsorption
selectivity for CO₂/C₂H₂. MUF-4-F can be derived by F⁻/Cl⁻ ligand exchange of MUF-4.¹³⁹ Both MUF-4-F and MFU-4 possess alternating large pore and small pore cavities but have different connecting windows (3.7 Å and 2.2 Å, respectively). C₂H₂ molecules can easily enter MFU-4-F. Equilibrium and kinetic adsorption studies revealed that MFU-4-F exhibits a higher C₂H₂ (6.66 mmol g⁻¹) uptake than CO₂ (3.24 mmol g⁻¹) at 300 K and 1 bar and shows a fast adsorption rate for both gases. In contrast, MFU-4 exhibits high kinetic selectivity for uptake of CO₂ over C₂H₂ up to 3360 at 300 K. Computational studies revealed that C₂H₂ was blocked by the smaller windows created by the Zn–Cl groups in MUF-4. Breakthrough experiments demonstrated that high purity (>98%) C₂H₂ can be obtained directly from a 50/50 CO₂/C₂H₂ mixture in MUF-4.

2.5. C₃H₆ and C₃H₈ separation

Propylene (C₃H₆) is also an essential industrial feedstock with large demand that is only lower than that of ethylene. The industrial production of C₃H₆ inevitably contains a certain amount of propane (C₃H₈) impurity. However, they have very similar molecular sizes (C₃H₆: 3.8 × 4.0 × 6.5 Å³, and C₃H₈: 3.8 × 4.2 × 6.8 Å³), kinetic diameters (C₃H₆: 4.0 Å, and C₃H₈: 4.2 Å) and physical properties (boiling points of 189.3 and 194.7 K, respectively). Therefore, it is more challenging to tune the pore size for sieving separation of C₃H₆/C₃H₈, because they have highly similar molecular sizes and kinetic diameters, whereas possible changes of the size and shapes of MOF apertures may occur in the adsorption process, as many MOFs are actually flexible. Fortunately, significant research progress about highly efficient separation of C₃H₆/C₃H₈ has been recently realized by MOFs through rational structural design and modification of the pore size and pore surface.¹⁴⁹–¹⁶⁸

The incorporation of active sites in MOFs’ pore surface improves not only kinetic selectivity but also thermodynamic selectivity for gas separation. In 2019, Zhang et al. reported a MAF, MAF-23-O, which can be easily synthesized by heating the flexible prototype [Zn₂(btm)₂] (MAF-23, H₂btm = bis(5-methyl-1H-1,2,4-triazol-3-yl)methane) under oxygen gas flow (Fig. 13). Single-crystal structure analyses showed that MAF-23-O is isostructural to MAF-23 and contains half the amount of the oxidized btm⁻²⁻ ligands, namely, btk²⁻ (H₂btk = bis(5-methyl-1,2,4-triazol-3-yl)methane). This in situ ligand oxidative modification makes the framework more rigid and more hydrophilic. The IAST selectivity for C₃H₆/C₃H₈ in MAF-23-O was calculated to be 8-9, which was higher than that of MAF-23 (3-4). Moreover, C₃H₆ and C₃H₈ exhibit similar diffusion rates in MAF-23, but show very different diffusion rates in MAF-23-O with a high kinetic selectivity of 71. Theoretical calculations demonstrated that the exposed oxygen atoms in the framework of MAF-23-O can form strong C–H···O/N interaction with C₃H₈, improving the thermodynamic selectivity of
MAF-23-O for C₃H₆. Additionally, the decreased flexibility of the framework slows down the diffusion of C₃H₆, thus improving the kinetic selectivity. Breakthrough experiments revealed that MAF-23-O exhibits efficient separation for an equimolar C₃H₆/C₃H₈ mixture at 298 K and 1 bar with an adsorption selectivity of 15, which is 10 times that of MAF-23.

In 2016, Eddaoudi et al. reported a oxyfluoride-based MOF [Ni(pyr)₂(NbOF₅)]·2H₂O (NbOFFIVE-1-Ni, or KAUST-7, pyr = pyrazine) for selective adsorption of C₃H₆ from C₃H₈. KAUST-7 is isostructural to SIFSIX-3 and composed of Ni(II) pyrazine square-grid layers and (NbOF₅)₂⁻ pillars with a topology, exhibiting 1D channels with an aperture size of 3.0 Å and a periodic array of fluoride anions on the pore surface. Single-component sorption experiments revealed that KAUST-7 can adsorb ~60 mg g⁻¹ (1.43 mmol g⁻¹) C₃H₆ but negligible C₃H₈ uptake at 298 K and 1 bar. Breakthrough experiments demonstrated that C₃H₆ of 97% purity can be obtained from C₃H₆/C₃H₈ 50/50 mixed-gas by a packed column bed of KAUST-7, with a separation productivity of 0.6 mol g⁻¹. KAUST-7 also can adsorb C₃H₈ by pore-opening sorption behavior at 273 K.

In 2023, Chen et al. reported another SIFSIX MOF [Ni(WO₄)F₄·(pyz)₂] (UTSA-400) featuring 1D channels that can exclude C₃H₆ molecules and adsorb C₃H₈ molecules with a high binding affinity (Fig. 14). UTSA-400 shows an isostructural framework with SIFSIX-3 and NbOFFIVE-1-Ni, but with highly tilted pyrazine linkers owing to larger WO₄F₄²⁻ in contrast to SiF₆⁵⁻ and NbOF₅²⁻. The pore cavities in UTSA-400 are 6.7 × 5.5 × 3.7 Å³ with exposed oxide/fluoride pairs on the pore surface ( BET surface area: 226 m² g⁻¹) that can serve as the binding sites for propylene molecules. Single-component sorption results of UTSA-400 indicated a much higher C₃H₆ capacity (92.1 cm³ g⁻¹) than NbOFFIVE-1-Ni (54.3 cm³ g⁻¹) by 63%, at 1 bar and 298 K, which is also higher than those of Y-abtc (64.6 cm³ g⁻¹) and Co-gallate (66.6 cm³ g⁻¹). Under the same conditions, UTSA-400 showed negligible C₃H₈ uptake because of inaccessible inward diffusion of propane molecules. The Qₘ of UTSA-400 for C₃H₆ is 60.5 kJ mol⁻¹, being comparable to those of MOFs with OMSs (44–57 kJ mol⁻¹).

Breakthrough separation experiment demonstrated that polymer-grade (99.7%) propylene can be obtained from an equimolar C₃H₆/C₃H₈ mixture with a productivity of 56.7 L h⁻¹ L⁻¹. Besides size exclusion, the separation performance of UTSA-400 can also be attributed to strong C–H · · · O/F interactions, as confirmed by in situ infrared spectroscopy and DFT-D calculations.

In 2018, Li et al. studied four microporous MOFs, namely, Zr-bptc, Zr-abtc, Y-bptc, and Y-abtc, which were obtained by the combination of two analogous metal clusters (Zr₆ and Y₆) and two different ligands (abtc = 3,3',5,5'-azobenzene-tetracarboxylates, and bptc = 3,3',5,5'-biphenyltetracarboxylates). Among these materials, Y-abtc has cage-like pores connected through small windows, exhibiting fwt topology and optimal pore size (4.72 Å) that enables it to adsorb small C₃H₆ molecules (4.48 Å) with fast kinetics but completely exclude larger C₃H₈ molecules (5.1 Å). Single-component sorption experiments revealed that Zr-bptc exhibits similar adsorption capacities for C₃H₆ and C₃H₈, whereas its isostructural Y-bptc excludes both gases, attributable to the presence of equilibrium cations (dimethylammonium) in the Y-bptc affecting its pore size. In contrast, Y-abtc with the optimal pore size shows a high adsorption capacity for C₃H₆ (~2 mmol g⁻¹) and negligible C₃H₈ uptake at 298 K. Column breakthrough experiments indicated that polymer-grade C₃H₆ (99.5%) can be obtained from 5/95 C₃H₆/C₃H₈ mixtures by Y-abtc. Recently, the same group reported a new Y-based MOF, Y₆[OH]₆[eddi]₂(DMA)₂ (HIAM-301, H₄eddi = 5,5'-ethene-1,2-diy1)diosphthalic acid, and DMA = dimethylammonium), also...
exhibiting the molecular sieving separation of C$_3$H$_6$/C$_3$H$_8$ mixtures. HIAM-301 is composed of 12-connected Y$_6$(OH)$_8$(COO)$_{12}$ clusters bridged by 4-connected eddi$^4$/C0 linkers to form a 3D framework with ftw topology and a pore size of 4.6 Å. It is isostructural to Y-abtc and possesses distorted cubic cages (size: 10 $\times$ 10 Å$^2$), which provides better control over guest accessibility. Single-component adsorption isotherms revealed that HIAM-301 can adsorb 3.16 mmol g$^{-1}$ C$_3$H$_6$ and exhibit minor C$_3$H$_8$ adsorption (<0.3 mmol g$^{-1}$) at 298 K and 1 bar, resulting in a high IAST selectivity (>150) for equimolar C$_3$H$_6$/C$_3$H$_8$ under the same condition. The practical performance for separation of 5/95 C$_3$H$_6$/C$_3$H$_8$ was confirmed by dynamic breakthrough experiments with a high productivity of 46.4 cm$^3$ g$^{-1}$ (>99.5% purity).

In 2020, Chen et al. reported an ultramicroporous Co-gallate MOF [Co(C$_7$O$_5$H$_4$)] (Co-gallate) with 3D channels, which exhibits efficient C$_3$H$_6$/C$_3$H$_8$ separation by molecular sieving effect. Co-gallate shows elliptical windows (size: 4.2 $\times$ 5.1 Å$^2$), which are precisely between the sizes of C$_3$H$_8$ and C$_3$H$_6$ (Fig. 15). Single-component adsorption isotherms showed that Co-gallate has a high adsorption capacity of C$_3$H$_6$ (66.6 cm$^3$ cm$^{-3}$, 1.79 mmol g$^{-1}$), whereas the adsorption of C$_3$H$_8$ (5.2 cm$^3$ cm$^{-3}$, 0.14 mmol g$^{-1}$) is minor at 298 K. The IAST selectivity of Co-gallate for a 50/50 C$_3$H$_6$/C$_3$H$_8$ mixture was calculated up to 330 at 1 bar and 298 K. Fixed-bed breakthrough experiments further confirmed its molecular sieving separation performance for 50/50 C$_3$H$_6$/C$_3$H$_8$, with a C$_3$H$_6$ productivity of 36.4 cm$^3$ cm$^{-3}$, 0.98 mmol g$^{-1}$ (97.7%+ purity).

In 2021, Li et al. reported a MOF (JNU-3a) featuring 1D channels (size $\sim$ 4.5 $\times$ 5.3 Å$^2$) attached with small pockets arranged on both sides for C$_3$H$_6$/C$_3$H$_8$ separation, where 1D channels could facilitate fast adsorption–desorption kinetics (Fig. 16). In addition, the small pockets were connected with the 1D channel through small apertures (3.7 Å) that can undergo gate-opening for C$_3$H$_6$ and C$_3$H$_8$ at different partial pressures. JNU-3a exhibits a stepwise adsorption isotherm and shows temperature-dependent gate-opening for C$_3$H$_6$ and C$_3$H$_8$, where C$_3$H$_8$ exhibits a higher gate-opening pressure than C$_3$H$_6$. Therefore, the high selectivity of JNU-3a for C$_3$H$_6$/C$_3$H$_8$ can be obtained at optimal temperature (303 K). JNU-3a can adsorb 58.6 cm$^3$ cm$^{-3}$ (2.62 mmol g$^{-1}$) C$_3$H$_6$ at 303 K, and the C$_3$H$_6$ packing density inside JNU-3a was calculated to be 404 g L$^{-1}$. The dynamic feature of pore aperture was further revealed by single-crystal X-ray diffraction and theoretical calculation studies. Breakthrough experiment revealed that high-purity C$_3$H$_6$ (>99.5%) can be obtained from a 50/50 C$_3$H$_6$/C$_3$H$_8$ mixture by JNU-3a. After applying helium purge to those adsorbed gases, C$_3$H$_6$ was collected with a maximum productivity of 53.5 L kg$^{-1}$. The unique pore structure reported in this work would inspire future design of novel MOFs for application in adsorptive separation.

In 2023, Bai et al. reported a supertetrahedral-cluster (Cu$_{10}$O$_{13}$)-based MOF (NTU-85) which possesses square-shaped 1D channels that host lattice water molecules. The partial lattice water molecules can be precisely removed to form a...
MOF (NTU-85-WNT) of pore surface decorated with water nanotubes (~4.5 Å). Single-component sorption results of NTU-85-WNT indicated a rapid C$_3$H$_6$ uptake (20.9 mL mL$^{-1}$, 0.45 mmol g$^{-1}$), while the adsorption of C$_3$H$_8$ (0.13 mL mL$^{-1}$, 0.003 mmol g$^{-1}$) at 298 K can be neglected. The IAST selectivity of NTU-85-WNT for an equimolar C$_3$H$_6$/C$_3$H$_8$ mixture reaches up to 1570. Fixed-bed breakthrough experiments further confirmed its molecular sieving performance for an equimolar C$_3$H$_6$/C$_3$H$_8$ mixture, with a C$_3$H$_6$ productivity of 1.6 mL mL$^{-1}$ (98.8% purity). It is worth noting that high purity C$_3$H$_6$ (>99.5%) can be obtained in one adsorption–desorption cycle due to the efficient sieving performance.

An optimal pore size combined with high-density binding sites can efficiently separate C$_3$H$_6$/C$_3$H$_8$, allowing for high-density stacking of C$_3$H$_6$ and maximizing its adsorption capacity. Recently, Chen et al. reported a robust Hofmann-type MOF, [Co(pyz-NH$_2$)Ni(CN)$_4$]$_n$ (ZJU-75a, pyz-NH$_2$ = 2-aminopyrazine), with high-density binding sites, showing excellent separation performance for C$_3$H$_6$/C$_3$H$_8$. ZJU-75a exhibits an isooctructural framework with [Co(pyz)Ni(CN)$_4$]$_n$ (ZJU-74a, pyz = pyrazine), decorated with amino groups. ZJU-75a exhibits an appropriate pore size (4.1 × 4.4 Å$^2$) and OMSs of high density (8.89 mmol cm$^{-3}$). Single-component sorption isotherms showed that ZJU-75a and ZJU-74a exhibit comparable C$_3$H$_6$ uptakes of 104.3 cm$^3$ cm$^{-3}$ (3.31 mmol g$^{-1}$) and 111.4 cm$^3$ cm$^{-3}$ (3.68 mmol g$^{-1}$) at 1 bar and 296 K, respectively, whereas the C$_3$H$_8$ adsorption capacity of ZJU-75a (73.5 cm$^3$ cm$^{-3}$, 2.33 mmol g$^{-1}$) is obviously smaller than that of ZJU-74a (103.6 cm$^3$ cm$^{-3}$, 3.42 mmol g$^{-1}$). Thus, the IAST selectivity of ZJU-75a for C$_3$H$_6$/C$_3$H$_8$ was calculated to be 54.2 at 296 K and 1 bar, much higher than that of ZJU-74a (4.3). The breakthrough studies indicate that ZJU-75a can yield C$_3$H$_6$ of high-purity (99.5%+) with a productivity of 18.7 L kg$^{-1}$ and separation factor of 14.7. Structural and computational studies indicated that high-density OMSs and nitrogen atoms (from [Ni(CN)$_4$]$_{2n}$ units and -NH$_2$ groups) in ZJU-75a contribute jointly to the strong adsorption of C$_3$H$_6$, thus resulting in a high C$_3$H$_6$ storage density (0.818 g mL$^{-1}$).

C$_3$H$_8$-selective adsorptive separation would be a relatively simple and energy-efficient way to get pure propylene. However, the differences of the molecular size (~0.5 Å) and polarizability (C$_3$H$_6$: 62.6 × 10$^{-25}$, and C$_3$H$_8$: 62.9–63.7 × 10$^{-25}$ cm$^3$) between C$_3$H$_6$ and C$_3$H$_8$ are smaller than those between C$_2$H$_4$ and C$_2$H$_6$. So far, only a few C$_3$H$_8$-selective MOFs have been reported. In 2022, Xing et al. reported an ultramicroporous pillared layered MOF [Co(IPA)(DPG)]$_n$ (PCP-IPA, IPA = isophthalic acid, and DPG = meso-ß,ß-di(4-pyridyl)glycol) featuring 1D pores (size ~4.7 × 5.6 Å$^2$) and periodic parallel-aligned isophthalic acid units on the pore surface, exhibiting an excellent selectivity for C$_2$H$_6$ and C$_3$H$_8$. Although C$_2$H$_6$ and C$_3$H$_8$ have different molecular sizes, the suitable pore size of PCP-IPA facilitates their directional adsorption and maximizes the interaction between PCP-IPA and C$_3$H$_8$. Therefore, PCP-IPA exhibits not only a C$_3$H$_6$/C$_3$H$_8$ (50/50) IAST selectivity of 2.48 but also a relatively high adsorption selectivity (2.80) for C$_2$H$_6$/C$_2$H$_4$ (50/50) at 1.0 bar and 298 K. Both C$_3$H$_6$ and C$_3$H$_8$ can be directly obtained with high purity (99.99%) through a fixed-bed column from C$_3$H$_6$/C$_3$H$_8$ (50/50) and C$_2$H$_6$/C$_2$H$_4$ (50/50) mixtures, respectively, affording a high C$_3$H$_6$ productivity (15.23 L kg$^{-1}$) and excellent C$_2$H$_4$ productivity (26.2 L kg$^{-1}$). Modeling simulation studies revealed that tighter and more multiple vdW interactions (C–H⋅⋅⋅O/C) can be formed between paraffins and PCP-IPA compared to olefins.

Very recently, Li et al. reported two isostructural MOFs (FDMOF-1 and FDMOF-2) functionalized with different amounts of fluorinated functional groups (–CF₃), showing strong affinity for C₃H₈ over C₃H₆ (Fig. 17). Compared with the prototype MOF Zn₂(BDC)₂(DABCO) (Zn-DMOF, BDC = 1,4-benzenedicarboxylate), the introduction of different amounts of –CF₃ groups into a MOF not only increases its stability but also adjusts the pore size/shape. Therefore, FDMOF-2 with the maximal amount of –CF₃ groups shows the smallest aperture (5.1 Å) and exhibits the optimal C₃H₈ affinity. Single-component sorption isotherms showed that FDMOF-2 displays a higher C₃H₈ uptake of 140 cm³ cm⁻³ (5.04 mmol g⁻¹) but a lower C₃H₆ uptake of 115 cm³ cm⁻³ (4.14 mmol g⁻¹), resulting in the IAST selectivity for 50/50 C₃H₈/C₃H₆ up to 2.18 at 298 K and 1 bar. Breakthrough experiments revealed that high purity (/>99.99%) C₃H₆ can be directly produced from 50/50 C₃H₈/C₃H₆ mixtures, affording 0.501 mol L⁻¹ production of C₃H₆. It is worth pointing out that the excellent separation performance of FDMOF-2 for C₃H₈/C₃H₆ can be maintained under 70% relative humidity conditions.

Single-crystal X-ray diffraction and theoretical calculation studies confirmed that the strong affinity of UTSA-400 for C₃H₈ can be attributed to strong non-classical C–H···π/F hydrogen-bonding interactions, resulting in a stronger binding affinity for C₃H₈ vs. C₃H₆ with an initial ΔQs value difference of −3.7 kJ mol⁻¹.

2.6. C₃H₄/C₃H₆ separation

The removal of traces of propylene (C₃H₄ of ~1%) from propylene is essential to obtain high purity propylene (C₃H₆). However, it is very difficult to separate trace amounts of C₃H₄ from C₃H₆, because their chemical/physical properties and molecular sizes (C₃H₄: 6.2 × 3.8 × 3.8 Å³; C₃H₆: 6.5 × 4.0 × 4.2 Å³) are highly similar. Nevertheless, some MOFs have been reported to show great potential for the separation of C₃H₄/C₃H₆.

In 2017, Chen et al. reported a flexible-robust MOF [Cu(bpy)₂−(OTf)₂] (ELM-12, bpy = 4,4'-bipyridine, and OTf⁻ = trifluoromethanesulfonate) which exhibits excellent performance for removing trace C₃H₄ from a 1/99 C₃H₄/C₃H₆ mixture. ELM-12 composed of 2D square-grid sheets with dynamic dangling OTf⁻ groups exhibit two kinds of cavities of different shapes and sizes (C₃H₄: 6.2 × 3.8 × 3.8 Å³; C₃H₆: 6.5 × 4.0 × 4.2 Å³) (Fig. 18). Single-component adsorption isotherms revealed that ELM-12 shows a sharp increasing adsorption for C₃H₆ with an uptake of 1.83 mmol g⁻¹ at 298 K and 1 bar, as well as a large ΔQs.
of 60.6 kJ mol$^{-1}$ for C$_3$H$_6$, indicating its strong interaction with the C$_3$H$_6$ molecule. In contrast, both the uptake capacity (0.67 mmol g$^{-1}$ at 0.1 bar and 298 K) and $Q_{st}$ (15.8 kJ mol$^{-1}$) of ELM-12 for C$_3$H$_6$ are significantly lower. The multiple interactions, such as weak or non-classical C-D$\cdots$O hydrogen bonds, between ELM-12 and C$_3$D$_4$ molecules were further confirmed by high-resolution neutron powder diffraction studies. Breakthrough experiments demonstrated that high purity (99.9998%) of C$_3$H$_6$ can be obtained from a 1/99 C$_3$H$_4$/$C_3$H$_6$ mixture.

In 2018, Chen et al. studied a series of MOFs with different types of structures, functionalities, and pore sizes (Fig. 19). Besides for highly selective C$_2$H$_2$/C$_2$H$_4$ separation, SIFSIX-type MOFs such as SIFX-1-Cu, SIFSIX-2-Cu-i, SIFSIX-3-Ni, and UTSA-200 also exhibit strong binding affinities for C$_3$H$_4$ compared to C$_3$H$_6$ and show high C$_3$H$_4$ adsorption capacities at very
low pressure. The former three SIFSIX-MOFs show slightly larger pore sizes than both C$_2$H$_4$ and C$_3$H$_6$, which lead to moderate C$_3$H$_4$/C$_3$H$_6$ selectivity. The activated UTSA-200 with the optimal pore size (3.4 Å) and strong binding sites has the best separation performance for C$_2$H$_4$/C$_3$H$_6$. Single-component adsorption isotherms revealed that UTSA-200 exhibits the highest C$_2$H$_4$ uptake capacity of 95 cm$^3$ cm$^{-3}$ (2.99 mmol g$^{-1}$) at 0.01 bar and 298 K, while adsorbs negligible C$_3$H$_6$ (0.33 mmol g$^{-1}$, at 298 K and 0.4 bar), resulting in an extremely high IAST selectivity of 20 000 for 1/99 C$_3$H$_4$/C$_3$H$_6$ at 298 K and 1 bar. Breakthrough experiments demonstrated that high purity (99.9999%) C$_3$H$_6$ can be yielded from 1 : 99 and 0.1 : 99.9 C$_3$H$_4$/C$_3$H$_6$ mixtures with a productivity of 62.9 mmol g$^{-1}$ and 143.8 mmol g$^{-1}$, respectively. Neutron powder diffraction studies and DFT-D calculations revealed that C$_3$H$_4$ molecules can open the pores of UTSA-200 and form strong C–H···F interac-
tions with the framework.

In 2022, Xing et al. reported a flexible MOF GeFSIX-14-Cu-i (ZU-33, GeFSIX = hexafluorogermanate, and 14 = 4,4'-azopyridine), which exhibits guest/temperature-dependent structural dynamics and shows strong binding affinity towards acetylene and propadiene. Single-component gas adsorption experiments revealed that ZU-33 shows a steep uptake for alkynes (acetylene and propyne) and propadiene at low pressure (0.01 bar) and 303 K, while there is a threshold pressure for olefin adsorption and a size exclusion effect for alkanes. In addition, for C$_3$H$_4$ that is smaller than propyne and propadiene regarding the kinetic diameters, ZU-33 nearly inhibits C$_2$H$_4$ molecules to diffuse into its pores, suggesting the inverse size sieving below 0.5 bar at 303 K. Molecular simulations and single-crystal X-ray diffraction revealed that the interactions between the alkyne molecules (propyne and propadiene) and ZU-33 are more intense, thus requiring less input energy to overcome the energy barrier for the structural deformation. Breakthrough tests on a ZU-33 packed column verified that acetylene and propadiene can be directly removed from simulated cracking gases.

2.7. C$_4$ hydrocarbon separation

C$_4$ olefins including 1,3-butadiene (1,3-C$_4$H$_6$), 1-butene (n-C$_4$H$_8$) and isobutene (i-C$_4$H$_8$) are important raw materials for the production of synthetic rubbers and chemicals. However, C$_4$ olefin separation represents one of the great challenges in hydrocarbon purification owing to the similar structures and physical properties.

Xing et al. reported several interpenetrated anion-pillared ultra-microporous MOFs, such as GeFSIX-2-Cu-i (ZU-32), NbFSIX-2-Cu-i (ZU-52) and GeFSIX-14-Cu-i (ZU-33), and realized highly efficient separation of C$_4$ olefins through molecular recognition. This series of materials show ultrafine-tuning of the pore size/shape (4.20–4.83 Å) by replacing pillared inorganic anions with different bulks and different lengths of organic ligands. Among them, NbFSIX-2-Cu-i with a pore aperture size of 4.31 Å (F–F distance) exhibits high C$_3$H$_6$ (2.64 mmol g$^{-1}$) and n-C$_4$H$_8$ (2.26 mmol g$^{-1}$) uptake but negligible i-C$_4$H$_8$ uptake (0.48 mmol g$^{-1}$), showing uptake selectivities of about 5.00 and 5.74 for n-C$_3$H$_6$/i-C$_4$H$_8$ and C$_3$H$_6$/i-C$_4$H$_8$, respectively. In contrast, GeFSIX-14-Cu-i shows a smaller pore size of 4.20 Å (F–F distance), resulting in negligible adsorption of n-C$_3$H$_6$ (0.57 mmol g$^{-1}$) and i-C$_4$H$_8$ (0.42 mmol g$^{-1}$), but still retaining large uptake for C$_3$H$_6$ (2.67 mmol g$^{-1}$), accompanying a gate-opening adsorption behavior for C$_4$H$_8$. Breakthrough experiments demonstrated that these materials can efficiently separate C$_3$H$_6$ from C$_3$H$_6$/n-C$_3$H$_6$/i-C$_4$H$_8$/He (50/15/30/5) mixtures, as well as efficiently separate C$_3$H$_6$/n-C$_3$H$_6$ (50/50) and n-C$_3$H$_6$/i-C$_4$H$_8$ (50/50) mixtures.

Because of its high degree of unsaturation and strong coordination ability, 1,3-C$_4$H$_6$ is commonly adsorbed preferentially over other C$_4$ hydrocarbons by MOFs with functional sites. It is thus energy-intensive and might induce undesired polymerization as the purification involves capture of 1,3-C$_4$H$_6$ and

![Fig. 19](image-url) (a) DFT-D optimized structure and binding sites of UTSA-200 ⊘ C$_3$H$_4$. (b) C$_3$H$_4$ and C$_3$H$_6$ adsorption isotherms of UTSA-200 at 298 K. Reprinted with permission from ref. 182. Copyright 2018 Wiley-VCH.
its subsequent release through heating in general. Zhang et al. noticed that the collaborative interactions between the host framework and guest flexibility can significantly change the conformation of certain C4 hydrocarbons and thus exhibit abnormal adsorption and reversed selectivity (Fig. 20).

In particular, a hydrophilic pore of a MAF with free N atoms, namely, [Zn2(btm)]2 (MAF-23), with 1D quasi-discrete pores (aperture size 3.6 Å, and cage size ca. 6 Å) was employed for separation of four hydrocarbons, n-C4H10, i-C4H10, C4H10, and 1,3-C4H6. As revealed by experimental and DFT calculations, n-C4H10, the most similar one to 1,3-C4H6 among these gas molecules, adopts a metastable cis conformation to form stronger non-classical C–H–N interactions, and hence has a significantly stronger binding affinity than 1,3-C4H6. It was found that 1,3-C4H6 can be first eluted during the breakthrough operation under ambient conditions, and directly purified for the desired purity (≥99.5%) to meet the industrial requirement in one single separation operation.

The separation of C4 geometric isomers is also a challenging separation process, among which the separation of trans/cis-2-butene is of prime importance to increase the value of C4 olefins. Ren et al. reported that Mg-gallate (M = Ni, Mg, and Co), featuring oval-shaped pores, are ideally suitable for shape-selective separation of trans/cis-2-butene through their difference in the minimum molecular cross-section sizes, in addition to a highly efficient separation of 1,3-butadiene, 1-butene, and i-butene. Mg-gallate displays a narrow pore window size of 3.6 × 4.6 Å², capturing the smaller trans-2-butene (3.5 × 4.6 Å²) while excluding the slightly larger cis-2-butene (3.6 × 4.9 Å²), affording a high trans/cis-2-butene uptake selectivity of 3.19 at 298 K and 1.0 bar in single-component adsorption isotherms. DFT-D study showed that Mg-gallate interacts with trans-2-butene and 1,3-butadiene through short distances of intramolecular C⋯H–O interactions (C–H distances 2.57–2.83 Å and 2.45–2.79 Å, respectively).

The separation of isomeric C4 paraffins is also an important task in the petrochemical industry. Zhong et al. regulated the pore aperture of the cage-like Zn-bzc by stepwise installation of methyl groups on its narrow aperture to achieve both molecular-sieving separation and a high n-C4H10 uptake. The resulting Zn-bzc-2CH3 is not only a new benchmark adsorbent featuring molecular sieving for n-C4H10/iso-C4H10 separation and a high n-C4H10 adsorption capacity (2.42 mmol g⁻¹), but also hydrophobic to eliminate the negative effect of water vapor on gas separation under humid conditions. Breakthrough tests proved that high-purity i-C4H10 (99.99%) can be collected. The minimum energy path of n-C4H10 and i-C4H10 from cage to cage passing through the narrow aperture was determined for Zn-bzc-CH3 (n = 0, 1, 2), and the results suggested easy transports of both n-C4H10 and i-C4H10 for the larger apertures of the parent Zn-bzc MOF.

2.8. Linear/branched alkane separation
The branched C5–C8 paraffins are major components in high-octane gasoline, which have relatively higher Research Octane Number (RON) values than their normal counterparts. To boost octane ratings in gasoline, the separation of linear alkanes

---

Fig. 20 (a) Schematic diagrams of controlling the guest conformation through the quasi-discrete pore in MAF-23. (b) Breakthrough curves of MAF-23 for a 5:2:2:1 C4H8/n-C4H10/i-C4H10/C4H10 mixture. (c) Crystal structures of host–guest complexes of C4H8, n-C4H10, i-C4H10, and C4H10. Reprinted with permission from ref. 193. Copyright 2017 the American Association for the Advancement of Science.
from their branched isomers is very important in the petroleum industry, which is traditionally done by energy-intensive distillation processes.

Eddaoudi et al. reported two new 12-connected rare-earth metal (Y$^{3+}$ and Tb$^{3+}$) fumarate based fcu-MOFs with both octahedral and tetrahedral cages that were solely interconnected with triangular windows of aperture size ca. 4.7 Å, and discovered that both of them can act as a adsorbate-size cut-off for the total sieving of C$_4$ and C$_5$ branched paraffins.$^{196}$

In addition, Li et al. prepared two Zr-MOF compounds, Zr-bptc and Zr-abtc, which are highly stable with optimal pore structures for the separation of C$_6$ alkane isomers (Fig. 21).$^{197}$ For instance, Zr-abtc featuring an scu-type structure with 1D channels ($d = 7$ Å) accommodates all C$_6$ alkane isomers ($n$-hexane, 3-methylpentane and 2,3-dimethylbutane), but favors $n$-hexane because of its stronger interactions with the pore surface, resulting in a mono/dibranched separation factor (≈1.3) in the breakthrough test.

In 2020, Li et al. reported a new flexible MOF, calcium chloranilate (HIAM-203), which specially possesses chloro-decorated 1D channels.$^{198}$ HIAM-203 exhibits structural flexibility upon adsorption of C$_6$ alkanes with different branching, as well as similar temperature-dependent adsorption behavior toward alkane isomers. It can take up a plentiful amount of $n$-hexane and 3-methylpentane at 30 °C, but completely excludes 2,2-dimethylbutane, while at 150 °C 3-methylpentane is also excluded. This phenomenon may be rationalized by the significant difference in binding affinity near the pore aperture of HIAM-203. As the pore size of HIAM-203 (5.6 Å) is between the kinetic diameters of 3-methylpentane (5.5 Å) and 2,2-dimethylbutane (6.2 Å), it thus inhibits the diffusion of 2,2-dimethylbutane.

In 2023, Bao et al. employed the Hofmann-type MOFs, [M(pz)Ni(CN)$_4$] (M = Co and Ni) to demonstrate similar temperature-swing molecular exclusion for separation of hexane isomers.$^{199}$ CopzNi displays excellent separation efficiency for linear/mono-branched and mono-branched/di-branched alkanes with the highest adsorption capacity to date. CopzNi exhibits lower-energy regeneration, scalability, recyclability and high stability, representing a promising candidate for relevant separation processes.

There are also needs for purification of valuable C$_5$–C$_7$ olefins. Isoprene, which accounts for 15–25% of C$_5$ fractions including important olefins like 1-pentene and trans-2-pentene, is widely used in the production of synthetic rubber, pharmaceutical and pesticide intermediates.$^{200}$ The regeneration and desorption efficiency should also be taken into account for separation.$^{201}$ Cui et al. found that anion-pillared hybrid porous materials, namely, ZU-62 (also termed NbOFFIVE-2-Cu-i) and TIFSIX-2-Cu-i, exhibit a good separation performance for C$_5$ olefin mixtures (trans-2-pentene, 1-pentene and isoprene).$^{202}$ Owing to a contraction of pore aperture originating from the rotation of 4,4’-dipyridylacetylene ligand, ZU-62 excludes the relatively large molecule of isoprene in the low pressure range (0–6 kPa), while
TIFSIX-2-Cu-i is able to distinguish the three C₅ olefins with a high uptake of trans-2-pentene (3.1 mmol g⁻¹), superior to that of zeolite 5A (2.0 mmol g⁻¹). DFT-D calculations confirmed that the selective adsorption was achieved by a favorable electrostatic environment as well as suitable pore confinement. Also, the regeneration tests showed that C₅ olefins can be easily desorbed from ZU-62 and TIFSIX-2-Cu-i at 298 K.

2.9. Aromatic isomer separation

The separation of C₈ aromatic compounds (xylene isomers, ethylbenzene and styrene) is also one of the important separations. Tremendous efforts have been devoted to developing MOF adsorbents for relevant separations. Most of these adsorbents contain aromatic organic ligands, in which the phenyl or heterocycle rings allow strong π-π stacking interactions with C₈ aromatic molecules to facilitate the adsorption.

MOFs featuring structural flexibility like breathing or gate-opening have been applied for separation of aromatic isomers. Li et al. reported that a stacked 1D manganese-based MOF [Mn(dhbq)(H₂O)] (Mn-dhbq, H₂dhbq = 2,5-dihydroxy-1,4-benzoquinone) exhibits temperature-dependent discriminative adsorption of xylene isomers owing to reversible framework swelling. At 363 K, pX can be fully intercepted from the pX/mX/oX ternary mixture by a column of Mn-dhbq, whereas the effluent of the mX/oX mixture can be further separated by another column of Mn-dhbq at a lower temperature (303 K) where mainly oX finally flows out. The purity of pX is over 97% collected during the desorption cycle when using 1,4-diethylbenzene as an eluent at 433 K for 1 hour after liquid-phase adsorption of a quaternary mixture (pX/mX/oX/EB, 22/22/50/6) at 393 K. DFT calculations indicated that the temperature-dependent flexibility between 1D coordination chains (different degrees of swelling at different temperatures) endows such selective adsorption of xylene isomers through π-π stacking interactions with the aromatic ligand.

Xing et al. reported a flexible anion pillared MOF [Ni(bpy)₃(NbOF₅)] (ZU-61) with pcu topology and a pore size of 7.8 Å exhibiting efficient separation performance for xylene isomer. Single-component adsorption revealed that ZU-61 shows a lower low-pressure uptake for mX and oX than pX at 0.01 bar and 333 K, as well as a higher capacity for mX (3.4 mmol g⁻¹) and oX (3.2 mmol g⁻¹). Breakthrough experiments for a 1:1:1 pX/mX/oX mixture confirmed that high purity (>99.9%) pX can elute from the column first, and then followed by mX and oX. The excellent performance for xylene isomer separation can be attributed to the rotational NbOF₅⁻ anions, which allows adaptive host-guest interaction (C-H···F interactions) depending on the shape of the xylene isomer, as confirmed by DFT calculations and crystallographic studies. These results showed that ZU-61 exhibits great potential for the purification of pX.

Given that all xylene isomers contain phenyl rings for π-π stacking interactions, another approach to enhance the separation selectivity would be utilizing the difference of their alkyl groups while inhibiting the interactions with phenyl rings. Yang et al. constructed a pillar-layered MOF Cu(bpdc)(ted)₀.₅ (ZUL-C3) by using poly-cycloalkane-type ligands to show a non-aromatic pore environment for xylene separation. The pore space of the MOF magnifies the difference of host-guest interactions with xylene isomers and ethylbenzene owing to their different distribution of methyl (ethyl) groups. Liquid-phase batch experiment indicated that this MOF can separate xylene isomers and ethylbenzene from each other, showing separation potential for oX/pX and oX/mX separation.

A flexible MOF, [Cuₓ][fbdim]ₚ-xylene (MAF-41 pX), showing a 3D hinged-fence-like framework and 1D channels (4.2 × 9.8 × 10.1 Å³ cavities and 3.9 × 6.7 Å² apertures), was demonstrated by Zhang et al. to exhibit unprecedented inverse molecular sieving (so called intermediate-sized molecular sieving) for the purification of styrene (Fig. 22). The framework structure can transform to a nonporous one upon removal of template molecules. The activated MAF-41 can adsorb styrene (ST) to restore the as-synthesized structure while totally excluding ethylbenzene (EB), toluene (Tol), and benzene (Bz). Styrene with a purity of 99.9%+ can be obtained from the multicomponent mixture after one single adsorption-desorption cycle because the pores are individually opened and simultaneously occupied by the target guest. The aperiodic pore opening is believed to avoid co-adsorption of guest molecules smaller than the opened pores. Kinetic sorption studies revealed that the EB/Tol/Bz...
adsorptions stayed quite low all the time, while the ST uptake of MAF-41 significantly increased for both the single-component and mixtures, which confirms no EB/Tol/Bz co-adsorption or replacement of ST in MAF-41. Although Cu(i) complexes and Cu(i)-based MOFs may have poor stability in air and/or water, guest-free MAF-41 did not collapse not only at temperatures up to 500°C, but also in boiling water for at least one week, and even remained stable in a solution of pH 3–14 at room temperature for at least 3 days.

In 2022, Li et al. reported a family of double-walled metal-dipyrazolate frameworks (BUT-53 to -58) composed of divalent metal ions and dipyrazolate ligands with different symmetries, lengths, and functionalities for trace benzene removal (Fig. 23).210 In this study, multiple merits, e.g., high stability, tunable pore, high adsorption capacity and selectivity, were integrated into these hydrophobic MOFs, which all exhibited high benzene uptakes (2.47–3.28 mmol g⁻¹) at room temperature and ultra-low pressures (<10 Pa). BUT-55 is the best-performing adsorbent for the capture of trace benzene among them. It shows an extremely long breakthrough time of ~8000 h g⁻¹ for a benzene-containing (10 ppm, 10 mL min⁻¹) gas mixture under both dry and humid (relative humidity = 50%) conditions. When the relative humidity was 80%, the breakthrough time decreased to ~6000 h g⁻¹, which is still much higher than that of other previously reported materials. After adsorption of benzene, BUT-55 can be regenerated under mild heating. As revealed by both the single-crystal structure of benzene-loaded BUT-55 and DFT calculations, multiple non-classical hydrogen-bonding C–H · X (X = N, O, π) interactions are the key to its strong affinity and high sensitivity toward benzene. The high benzene binding energy of BUT-55 contributes to its high adsorption selectivity of benzene over water or other volatile organic compounds (VOCs), such as cyclohexane and ethanol. It should also be pointed out that the BUT-55 sample is able to work continuously around one year under the breakthrough experiment conditions. In other words, a certain amount of BUT-55 can be used to capture trace airborne benzene for a long time due to its high benzene adsorption capacity under ultra-low pressures and high adsorption selectivity. The performance of these MOFs demonstrates high potential in the removal of benzene from ambient air.

Very recently, Mo et al. reported a flexible MOF, [Sr₂(BINDI)(H₂O)₂] (WYU-62, H₄BINDI = N,N₀-bis(5-isophthalic acid)-naphthalenediimide) with electron-deficient NDI cores, which shows fast adsorption of trace benzene vapor at low pressure,
accompanied by a fluorescence-enhanced sensing (limit of detection = 0.133 mg L\(^{-1}\)).\(^{211}\) WYU-62 could be easily obtained by immersing the as-synthesized MOF [Sr\(_2\)(BINDI)(DMF)(H\(_2\)O)] (MYU-61) in water, during which discrete 0D pores of MYU-61 have transformed to 1D channels (aperture size = 5.1 x 9.1 Å\(^2\)). Aromatic hydrocarbon vapor adsorption isotherms revealed that WYU-62a can show high benzene uptake at very low pressure (P/P\(_0\) < 0.01). DFT calculations and crystallographic studies indicated that electron-rich benzene was tightly wrapped between the two electron-deficient NDI moieties with strong π–π and C–H⋯π interactions. Therefore, it has excellent benzene adsorption capacity, whereas the accompanying host–guest charge transfer enables visual detection of trace benzene vapor.

3. MOF-based membranes for separating gaseous hydrocarbons

Though a variety of MOFs have been extensively studied for light-hydrocarbon purification in recent two decades, only a few have been fabricated into MOF-based mixed matrix membranes (MMMs), which may integrate the advantages of the separation performance of MOFs and processability of polymers for olefin/paraffin separation.\(^{212}\) For example, MAF-4 (or ZIF-8) and Zr-fum-fcu-MOF (or MOF-801) have been incorporated with membranes for C\(_3\)H\(_6\)/C\(_3\)H\(_8\) separation.\(^{213,214}\) Modification of MOF membranes with the composite ionic liquid/Ag\(^+\) (IL/Ag\(^+\)) can efficiently improve their olefin/paraffin separation properties. Yang et al. synthesized layered Zn\(_2\)(bim)\(_4\) membranes\(^{215}\) using the in situ interfacial assembly (ISIA)\(^{216}\) method and further modified them with varied IL/Ag\(^+\) composites.\(^{217}\) Adsorption isotherms for Zn\(_2\)(bim)\(_4\) powder and its IL/Ag\(^+\) modified sample showed that the adsorption capacity for olefin can significantly improve after modification with IL/Ag\(^+\) but the adsorption for paraffin shows negligible changes, which is attributed to the strong π-complexation of olefins with Ag\(^+\). Further study revealed that the pristine Zn\(_2\)(bim)\(_4\) membrane showed a C\(_3\)H\(_6\)/C\(_3\)H\(_8\) separation factor of 1.14 with a C\(_3\)H\(_8\) permeance of 106 GPU [SF\(_{C_3H_6/C_3H_8}\): 1.42, and P\(_{C_3H_8}\): 311] (Fig. 24). In contrast, the modified membranes exhibited a significant improvement in olefin/paraffin separation with the optimized C\(_3\)H\(_6\)/C\(_3\)H\(_8\) separation factor of 28.8 ± 3.8 with the C\(_3\)H\(_8\) permeance of 129.8 ± 40.4 GPU [SF\(_{C_3H_6/C_3H_8}\): 12.0 ± 2.2, and P\(_{C_3H_8}\): 45.6 ± 23.7 GPU]. The preferential binding affinity of Ag\(^+\) in IL for olefins facilitates the delivery of olefins in the modified Zn\(_2\)(bim)\(_4\) membranes. On the other hand, Ag\(^+\) filling in the space of laminated modified Zn\(_2\)(bim)\(_4\) membranes further blocks paraffin penetration and thus improves the olefin/paraffin selectivity. In addition to the composite modification membrane strategy, intrinsic structural regulation of MOF membranes is also crucial. Recently, a series of Zn\(_2\)(bim)\(_4\) membranes functionalized with different amounts of amino groups, namely, N\(_x\)Zn\(_2\)(bim)\(_4\) (x represents the molar ratio of raw 5-aminobenzimidazole, bim) were also investigated for separation.\(^{218}\) Among them, the N10-Zn\(_2\)(bim)\(_4\) membrane exhibits the highest H\(_2\)/CO\(_2\) separation performance with a separation factor of 1158 and a H\(_2\) permeance of 1417 GPU. Moreover, its ideal selectivities for H\(_2)/\text{CO}_2,\text{H}_2/\text{CH}_4\), and H\(_2)/\text{C}_3\text{H}_8\) were 829, 99, and 33, respectively, showing a distinct size exclusion effect for relatively large molecules.

Long et al. fabricated a series of membranes with M\(_2\)(dobdc) (M = Co, Ni, Mg, and Mn) as fillers and 6FDA-DAM as the primary polymer by reducing the filler size to the sub-100 nm level to specially improve the filler-polymer compatibility and dispersion.\(^{219}\) Among them, Ni\(_2\)(dobdc) showed the best C\(_2\)H\(_4\)/C\(_2\)H\(_6\) separation performance without reduction in selectivity even under high-pressure owing to the presence of strong and multiple nanocrystal-polymer interactions, which suppresses plasticization by reducing polymer chain mobility.

Polycrystalline MOF membranes are less explored but also important. Liu et al.\(^{220}\) have recently prepared a polycrystalline Co-gallate membrane with a reported freezing contra-diffusion protocol\(^{221}\) that can enable more accurate control over the reaction kinetics between metal ions and ligands to effectively tune the MOF nucleation and growth in the bulk solution. Maintaining the frozen state of the metal precursor inside the macroporous α-Al\(_2\)O\(_3\) substrate resulted in the formation of the preferred c-oriented and well-intergrown Co-gallate membrane with not only abundant open metal sites (at the increased missing-linker defects), but also reduced the thickness of the membrane. The multiscale structure endows the Co-gallate membrane with an outstanding C\(_2\)H\(_4)/C\(_2\)H\(_6\) separation performance superior to those of state-of-the-art membranes including polycrystalline MOF membranes, MOF-based MMMs, and polymeric membranes. The optimized C\(_2\)H\(_4)/C\(_2\)H\(_6\) selectivity is 8.3 with a C\(_2\)H\(_4\) permeance of 72.6 GPU. The resultant membrane also shows a negative correlation with the operation temperature and high long-term stability.

4. Conclusion and outlook

MOF materials have made significant progress in the separation of gaseous hydrocarbons in the past few years, which was achieved by rational control over their pore chemistry/size, affording an alternative separation technology for relevant applications. The high crystallinity of MOFs facilitates systematic and deep investigation on the exact adsorbent–adsorbate interactions in the type of porous materials for high separation performance, as demonstrated by their crystallographic studies on the host–guest interactions. Controlling the pore structure of MOF materials at high-accuracy level is applicable due to the high modularity and diverse functionality of MOFs, which facilitates highly efficient separation of methane, olefin/paraffin, alkyne/olefin, alkane isomers and aromatics. As outlined in this review, the collaborative control of the pore size and pore surface has been explored for the potential of MOFs for hydrocarbon separation. MOFs with high separation selectivities and large gas uptakes have been documented. The development of this realm has gradually turned to evaluate the potential of MOFs in practical separation processes, which required continuous research endeavors.
There are many important issues remaining unaddressed before further industrial and commercial usage of MOFs. Shaping/pelleting of MOFs would be the first step in actual processes given engineering considerations, but that would lead to loss of adsorption capacity; thus, further study on mechanical stabilities of MOFs might be necessary. Simultaneously, the diffusion kinetics of MOF pellets should be comprehensively investigated. There are also concerns on current research for evaluations of their separation performances through swing adsorption or membrane separation processes, as these evaluations mainly focus on evaluating candidate materials under simulated conditions rather than the actual applications. In relevant simulated evaluations, the presence of contaminants such as water has gradually got involved. In contrast, the actual gas streams would be more complicated, while the separation condition can be even harsher (under elevated pressures/temperatures), which require the adsorbents to show good stability and durability, including good water resistance and impurity tolerance. The long-term durability and regeneration of MOFs during separation processes have been rarely involved in current research. Moreover, systematic evaluation of materials production, including capital and operating costs, should be performed prior to large-scale deployments of MOF-based adsorptive separation technology. Solvent-free and continuous synthesis methods have been demonstrated to be applicable for MOFs, which show great potential for large-scale production of MOF materials. In addition, new technical issues such as thermal management during the adsorption process would come out when sorption is scaled up. For membrane-based separation, there are also several challenges although it is capable of direct production of pure gas and can be simply operated under mild conditions. Several mixed-matrix MOF-based membranes have been developed, which show large permeance differences for hydrocarbon separation. However, the processability, defect, compatibility, and scaling up in membrane fabrication as well as the permeability-selectivity trade-off are still quite challenging. In terms of membrane separation, molecular sieving of hydrocarbons is still highly desirable. As the structure numbers of MOFs keep growing, there are also emerging technologies like machine learning under artificial intelligence for the computational design and discovery of novel MOF materials, while automated chemistry for high-throughput screening is also possible by combination with robotics.

As promising adsorbent materials for hydrocarbon separation, MOFs with high separation performance can be synthesized by combination of rational control of their pore size and pore surface. Continuous collaborative efforts among scientists, engineers and industrial partners will promote the application of MOF adsorbents to scientifically and technologically important industrial hydrocarbon separation, which would reap great benefits for society.
