# Experimental evidence for $CH\cdots\pi$ interaction-mediated stabilization of the square form in phenylglycine-incorporated ascidiacyclamide†

Akiko Asano, (10 \* Katsuhiko Minoura, (10 Takeshi Yamada (10 and Mitsunobu Doi (10 )

Ascidiacyclamide [cyclo(-Ile-oxazoline-D-Val-thiazole-)2] is a cytotoxic cyclic peptide from ascidian. We examined the potential of the CH $\cdots$  $\pi$  interaction at the diagonal position of ascidiacyclamide by comparing the interactions of Ile, Val, Abu (2-aminobutyric acid) or Ala with Ile, Chg (cyclohexylglycine) or Phg (phenylglycine). In solution, ascidiacyclamides are in a conformational equilibrium between square and folded forms. The  $\mathsf{CH} \cdots \pi$  interaction is expected to contribute to stabilization of the square form, which enhances the peptides' cytotoxicity. The distances between the alkyl side chain of Xaa and the  $\pi$ -plane of Phg were estimated from the crystal structures. The conformational free energies ( $\Delta G^{\circ}$ ) determined through NMR-based quantitation indicated remarkable stabilization of the square form upon incorporation of Phg. These observations were consistent with the circular dichroism (CD) spectral measurements. Chemical shift perturbation studies suggested that stabilization of the square form of Phg-incorporated peptides was due to the  $CH\cdots\pi$  interaction with the alkyl side chain of Xaa. Greater enthalpic losses were caused during the folding process of Phg-incorporated peptides than Ile- or Chg-incorporated peptides. It is suggested that these enthalpic losses are relevant to the  $\mathsf{CH} \cdots \pi$  interaction energies, which must be disrupted during folding. In addition, the CH $\cdots\pi$  interactions in the Phq-incorporated peptides increased cytotoxicity.

# Introduction

Ascidiacycalmide (1a) is a cytotoxic cyclic peptide isolated from the marine invertebrate ascidian.1 The chemical sequence of 1a, cyclo(-Ile<sup>1</sup>-Oxz<sup>2</sup>-D-Val<sup>3</sup>-Thz<sup>4</sup>-Ile<sup>5</sup>-Oxz<sup>6</sup>-D-Val<sup>7</sup>-Thz<sup>8</sup>-), contains the five-membered heterocycles oxazoline (Oxz) and thiazole (Thz) and is characterized by  $C_2$ -symmetry (Fig. 1). Previous structural analyses showed that 1a assumes two major conformations, a "square form", which is the potentially cytotoxic structure, and a "folded form", and that the two conformations are in equilibrium in solution (Fig. 2).  $^{2-9}$  The conformational free energies ( $\Delta G^{\circ}$ ) of peptides bearing various substituents at the 1-position (or 5-position) were determined in NMR-based quantitative studies.8 The  $\Delta G_{298\text{K}}^{\circ}$  value for a peptide bearing an *n*-propyl group was nearly zero, while those for peptides bearing a substituent smaller than an n-propyl group (3a and 4a) were negative. On the other hand, the values for peptides bearing a bulkier

substituent than an n-propyl group (1a, 2a, 1b and 1c) were positive, which means that these peptides do not spontaneously fold at 298 K. This suggests that when 1a is in the square form, the bulky side chain of the substituted amino acid residue and the sec-butyl group of the Ile residue at the diagonal position are close to each other, and the dispersion force between these two functional groups prevents spontaneous folding. In particular, a dispersion force like a  $CH\cdots\pi$  interaction may be acting in peptides bearing a phenyl group (1c). While it is apparent that the van der Waals space occupied by a cyclohexyl group is larger than that of a planar phenyl group, the  $\Delta G_{298\,\mathrm{K}}^\circ$  value of 1c is three times that of 1b.

Phenylglycine (Phg) is a non-proteinogenic amino acid that is, nonetheless, a reported constituent of various natural peptidic products. Phg can be regarded as a truncated version of Phe that lacks the methylene group. In other words, Phg has a bulky aromatic side chain directly attached to the  $\alpha$ -carbon. It is therefore assumed that the degree of freedom of the aromatic ring side chain of Phg is strongly restricted, and the backbone conformation of a Phg-containing peptide is constrained accordingly. Furthermore, the electronic effects of aromatic moieties produce a weak noncovalent interaction, termed CH··· $\pi$ , which can contribute significantly to the proper folding and function of a protein. For instance,

Fig. 1 Chemical structures of ascidiacyclamide and the side chains (R) of the Xaa<sup>1</sup> residues and the side chains (R') of Yaa<sup>5</sup> residues. Peptides 1a–4a, 1b and 1c were previously synthesized.<sup>2,5,7,8</sup> Peptides Xb (X = 2 - 4) and Xc (X = 2 - 4) are newly synthesized asymmetric analogues.

many saccharide units possessing codirected CH groups can bind into  $\pi$  clouds of aromatic moieties in proteins. Thus, the  $\beta$ -p-galactose bound to lectin makes contact with

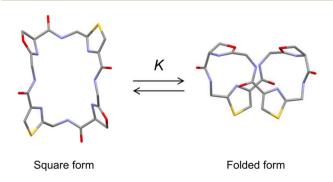

Fig. 2 Conformational equilibrium between the square and folded forms of ascidiacyclamide backbone. Carbon, nitrogen, oxygen and sulfur atoms are represented in gray, blue, red and yellow, respectively.

Phe131,<sup>23</sup> and the β-D-glucose bound to an *E. coli* chemoreceptor protein makes contact with Trp183.<sup>24</sup> The contact distances for these interactions were all within 3.5 Å within the X-ray structures. Given these steric and electronic features, it is expected that Phg would be a valuable pharmaceutical building block.

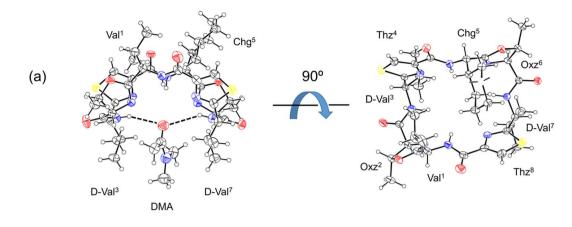

To gain additional details into the role of Phg in modulating the stability of square form, we investigated three series of peptides (Xa, Xb and Xc) in the present study (Fig. 1). The 5position residues of Xa, Xb and Xc peptides were Ile<sup>5</sup>, cyclohexylglycine (Chg<sup>5</sup>) and Phg<sup>5</sup>, respectively, and the 1-position residues were replaced with amino acid residues with substituents of various bulkiness [Ile (X = 1), Val (X = 2), 2-aminobutyric acid (Abu) (X = 3) and Ala (X = 4)]. Peptides **1a-4a**, **1b** and 1c were previously synthesized, while peptides 2b-4b, 2c, 3c and 4c were newly synthesized. Here we describe their structural characterization based on X-ray diffraction, circular dichroism (CD) spectroscopy and variable temperature (VT) <sup>1</sup>H NMR measurements. We then discuss the impact of Phg on stabilization of the square form, which is the potentially cytotoxic structure, by making comparisons among the Xa, Xb and Xc peptides.

# Results and discussion

### **Crystal structures**

The X-ray structures of 2b and 2c are shown in Fig. 3. For both 2b and 2c, each asymmetric unit contained the peptide molecule and one N,N-dimethylacetamide (DMA) molecule. Each peptide backbone was open, and the DMA molecule was located at the center of the peptide backbone, where it formed two hydrogen bonds with the peptide: N(D-Val<sup>3</sup>)-H···O(DMA) and  $N(D-Val^7)-H\cdots O(DMA)$  (Table 1). The previously reported crystal structure of 2a was also a square form,5 and there was no significant difference in the crystal structures among 2a, 2b and 2c, whose 1-position is a Val residue. The crystal structures of 1a, 1b and 1c, whose 1-position is an Ile residue, were also open.2,7,8 On the other hand, the crystal structure of 4a was folded.<sup>5</sup> In the Xa peptides, the crystal structures were folded when the Xaa<sup>1</sup> residue side chain was small. However, the crystal structures of 3a, 3b, 3c, 4b and 4c have not yet been determined.

The distances between the side chains of Xaa¹ and Phg⁵ were estimated by surveying the CH··· $\pi$  contacts for the sixmembered  $\pi$ -system, as described by Umezawa  $et~al.^{25-27}$  The distances from the H atoms of the Xaa¹ alkyl side chain to the  $\pi$ -orbital of the Phg⁵ residue in the crystal structures of 1c (ref. 7) and 2c are shown in Fig. 4. The  $\gamma^1$ H of Ile¹ and the  $\gamma^2$ H of Val¹ were oriented in the direction opposite to the  $\pi$ -plane of Phg⁵, and CH··· $\pi$  contacts were not observed. Within the crystal structure of 1c, the  $\delta$ H of Ile¹ was located above the  $\pi$ -plane, but 4.52 Å away. The CH/ $\pi$  distance of the  $\beta$ H was 3.71 Å, while that of the  $\gamma^2$ H was 3.17 Å, which was the closest to the  $\pi$ -orbital. Within the crystal structure of 2c, the CH/ $\pi$  distances of the  $\beta$ H and  $\gamma^1$ H of Val¹ were 4.00 Å and 3.75 Å, respectively. The sum of the van der Waals radii of the H and  $C_{sp²}$  was 2.90 Å (1.20 Å for C–H plus 1.70 Å for a half

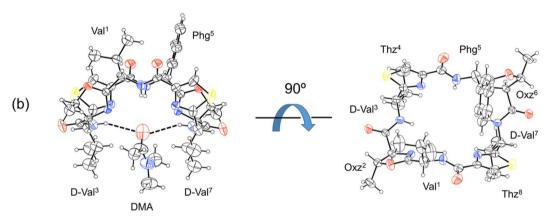

Fig. 3 Crystal structures of peptides 2b and 2c are presented in (a) and (b), respectively. Shown are the side (left) and top (right) views of the peptide rings. The dashed lines represent hydrogen bonds.

thickness of the aromatic molecule<sup>28,29</sup>), and more than 77% of organic crystals have been found to have CH/ $\pi$  distances shorter than 3.05 Å in database studies.<sup>25–27</sup> Although the CH/ $\pi$  distance between the  $\gamma^2$ H of Ile<sup>1</sup> and the  $\pi$ -orbital of Phg<sup>5</sup> in the crystal structure of **1c** was slightly longer than 3.05 Å, this distance makes it worth considering the presence of CH··· $\pi$  interactions.

### CD spectra

The conformational equilibrium between the square and folded forms can be measured based on the CD spectral

Table 1 Hydrogen bonds within the crystal structures of 2b and 2c

	Donor	Acceptor	Distance (Å)	Angle (°)
Peptide	D-H	A	$D{\cdots}A$	∠D-H···A
2b	N(D-Val³)–H	O(DMA)	3.223	150.45
	N(D-Val <sup>7</sup> )–H	O(DMA)	3.381	143.04
2c	N(D-Val³)–H	O(DMA)	3.387	150.63
	N(D-Val <sup>7</sup> )–H	O(DMA)	3.387	150.63

changes that occur while titrating 2,2,2-trifluoroethanol (TFE) into acetonitrile (CH3CN) solution of the peptide.5-9 For instance, the spectrum of 1a in CH<sub>3</sub>CN solution shows a positive band at around 205 nm and a negative band at around 245 nm, which is indicative of the square form. TFE titration led to decreases in  $[\theta]_{205}$  and increases in  $[\theta]_{245}$ , which indicate the conformation of the peptide was folding.5 By contrast, the spectrum of 4a in CH<sub>3</sub>CN solution shows a moderate positive band in the range of 230-260 nm, which is characteristic of the folded form. In other words, the conformational equilibrium position of 4a in CH<sub>3</sub>CN solution is significantly shifted in the forward direction, and there is almost no CD spectral change with TFE titration.5 The conformational equilibria for Xb and Xc (X = 2-4) were measured using the same protocol. Their spectral changes are shown in Fig. 5 along with the previously recorded spectra of 1a-4a, 5,8  $1b^8$  and  $1c^7$  for comparison.

When the spectral changes among Xa, Xb and Xc bearing the same  $Xaa^1$  were compared, very similar spectral changes were seen in Xa and Xb, but those in Xc indicated a large difference from the others. The spectra of all Xc peptides in  $CH_3CN$  solution showed clearer negative bands around 245 nm than those of the corresponding Xa and Xb peptides. In particular, the

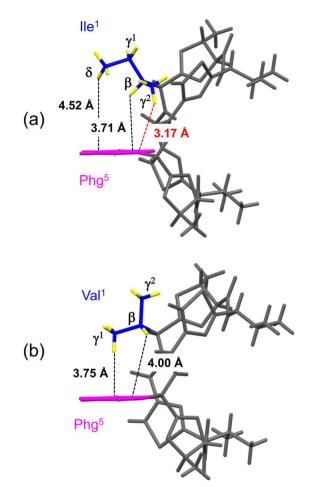

Fig. 4 Distances between the hydrogen atoms in the alkyl side chain of Xaa<sup>1</sup> and the  $\pi$ -orbital of Phg<sup>5</sup> within the crystal structures of 1c (a) and 2c (b). The alkyl carbon and hydrogen atoms of the Xaa<sup>1</sup> side chain and the aromatic moiety of the Phg<sup>5</sup> side chain are shown in blue, yellow and pink, respectively.

spectrum of 1c in  $CH_3CN$  solution was not significantly affected by TFE, suggesting the conformational equilibrium position of 1c is significantly shifted in the opposite direction. The incorporation of  $Chg^5$  did not affect the conformational equilibrium, but incorporation of  $Phg^5$  led to an apparent stabilization of the square form. For all Xa, Xb and Xc peptides, folding became easier as the bulkiness of the  $Xaa^1$  side chain declined ( $Ile^1 > Val^1 > Abu^1 > Ala^1$ ).

# VT-1H NMR

When the alkyl protons are close to the aromatic moiety, the result is a high-field shift of the alkyl proton chemical shift based on the ring-current effects of the aromatic ring. These high-field shifts can be probed to detect CH– $\pi$  interactions. The chemical shifts  $[\delta \text{ (ppm)}]$  for protons in the Xaa¹ alkyl side chain at 298 K and the chemical shift perturbations  $\Delta \delta_{(Xb-X)}$  (ppm) and  $\Delta \delta_{(Xc-Xa)}$  (ppm) are listed in Table 2. The values of  $\Delta \delta_{(Xb-Xa)}$  and  $\Delta \delta_{(Xc-Xa)}$  represent the magnitudes of the chemical shifts of alkyl protons in Xaa¹ caused by incorporation of Chg⁵ and Phg⁵, respectively. All absolute values of

 $\Delta \delta_{(Xb-Xa)}$  were very small, indicating that incorporation of Chg<sup>5</sup> had little effect on the chemical shift of the alkyl side chain of the Xaa1 residue. By contrast, the high-field shifts of the alkyl side chain of the Xaa1 residue caused by incorporation of Phg<sup>5</sup> were observed in all **Xc** peptides and resulted in negative  $\Delta \delta_{(Xc-Xa)}$  values for all Xaa<sup>1</sup> side chains in Xc peptides. In addition, variable temperature <sup>1</sup>H NMR spectroscopy (VT-1H NMR) was applied to examine the peptides every 10 K from 273 K to 333 K in CH<sub>3</sub>CN-d<sub>3</sub> solution. The temperature coefficients  $[\Delta \delta/\Delta T \text{ (ppb } \text{K}^{-1})]$  for the alkyl protons in the Xaa<sup>1</sup> side chains that were high-field shifted by the ring-current effects of the  $\pi$ -orbital of the Phg<sup>5</sup> residue are shown in Fig. 6. In 1c, the temperature coefficient for the  $\gamma^2$ H and βH in the Ile1 residue were 2.1 and 1.7 ppb K-1, respectively, which are significantly elevated values. Within the crystal structure of 1c, the  $\gamma^2$ H was located closest to the  $\pi$ plane of the Phg<sup>5</sup> residue, and the βH was second closest among the alkyl protons of the Ile1 residue. These observations suggest that the high temperature coefficient for the  $\gamma^2$ H in the Ile<sup>1</sup> residue is due to a decrease in the CH $\cdots \pi$ interaction with increasing temperature. The temperature coefficient of the  $\gamma H$  in the Abu<sup>1</sup> residue in 3c also had a high temperature coefficient (2.0 ppb K<sup>-1</sup>). Although the crystal structure of 3c has not yet been determined, the position of the  $\gamma H$  in the Abu<sup>1</sup> residue with respect to the  $\pi$ -plane of the Phg<sup>5</sup> residue may be similar to that of the  $\gamma^2$ H in the Ile<sup>1</sup> residue within the crystal structure of 1c. Within the crystal structure of 2c, one yH of the Val1 residue was oriented toward the  $\pi$ -plane of the Phg<sup>5</sup> residue while the other  $\gamma H$  was oriented toward the opposite side. However, the temperature coefficients of these two  $\gamma$  protons (1.2 and 1.4 ppb K<sup>-1</sup>, respectively) did not significantly differ.

# NMR-based quantification of the conformational equilibrium

The conformational equilibrium constants (K) of the peptides were determined based on the VT-H<sup>1</sup> NMR measurements. The thermodynamic parameters ( $\Delta H^{\circ}$ ,  $\Delta S^{\circ}$  and  $\Delta G^{\circ}$ ) were obtained from linear van't Hoff plots. These values are listed in Table 3. The  $\Delta H^{\circ}$  and  $\Delta S^{\circ}$  values for **1c** were not obtained because their K values exhibited no temperature dependency.8 The folding of all peptides is enthalpically favorable ( $\Delta H^{\circ} < 0$ ) and entropically unfavorable ( $\Delta S^{\circ} < 0$ ). This thermodynamic profile results from four hydrogen bonds  $[N(Xaa^{1})H\cdots O_{\gamma}(Oxz^{6}), N(D-Val^{3})H\cdots$  $O(Thz^8)$ ,  $N(Yaa^5)H\cdots O\gamma(Oxz^2)$  and  $N(D-Val^7)H\cdots O(Thz^4)$ formed within the folded form. The Xa and Xb peptides have similar thermodynamic profiles, whereas the thermodynamic profiles of Xc peptides differ from those of Xa and Xb. For Xc peptides, the enthalpic terms were more unfavorable than those for either the Xa or Xb peptides. This suggests that the nature of the interactions between Xaa<sup>1</sup> and Ile<sup>5</sup> or Chg<sup>5</sup> are similar, but the interaction of Xaa1 with Phg5 is distinct. For the conformational change from the square to the folded form, it is necessary to through the transition state (TS) without the interaction between Xaa<sup>1</sup> and Yaa<sup>5</sup> (Fig. 7). It is considered that the folding of Xc peptides causes an enthalpic loss

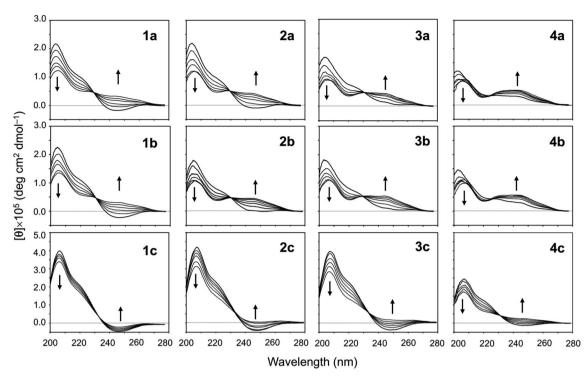

Fig. 5 CD spectral changes elicited by titration of TFE for peptides Xa, Xb and Xc (X = 1-4). The CD spectra for Xa, 1b and 1c were taken from previous reports. The spectra were measured in CH<sub>3</sub>CN solution while changing the TFE concentration (from 10% to 50% in increments of 10%).

 $[\Delta \Delta H^{\circ} = \Delta H_{Xc}^{\circ} - \Delta H_{Xa}^{\circ} \text{ (or } \Delta H_{Xb}^{\circ})]$  by an amount related to the energy of the CH··· $\pi$  interaction.

Plots of the temperature *versus*  $\Delta G^{\circ}$  values for all peptides are shown in Fig. 8. The  $\Delta G^{\circ}$  values for **1a**, **1b** and all Xc peptides were positive at every measured temperature. Comparing the results with the Xa and Xb peptides, the temperatures at which the  $\Delta G^{\circ}$  value of Xb peptides was zero were about 5 K higher than those for the corresponding Xa peptides (excluding **1a** and **1b**). This suggests that difficulty of spontaneous folding – *i.e.*, stability of the square form – among the peptides is in the order: Xc, Xb, Xa. The  $\Delta G^{\circ}$  values at 298 K for all peptides are shown in Fig. 9. The  $\Delta G^{\circ}$  value for Xa peptides increases with increases in the bulkiness of the

substituent of the Xaa¹ residue [methyl (X=4) < ethyl (X=3) < isopropyl (X=2) < sec-butyl (X=1)]. The same relationship between the bulkiness of the Xaa¹ side chain and the  $\Delta G_{298K}^{\circ}$  value was also seen with the **Xb** and **Xc** peptides. Among the **Xa**, **Xb** and **Xc** peptides, the  $\Delta G_{298K}^{\circ}$  values of the **Xc** peptides were clearly higher than those of the corresponding **Xa** and **Xb** peptides. These results suggest that in the square form of **Xc**, the CH··· $\pi$  interaction was added to the dispersion force between the side chains of Xaa¹ and Yaa⁵.

# Cytotoxicity

The cytotoxicities of all the peptides were assessed by determining the  $ED_{50}$  against HL-60 human myeloblastic leukemia

Table 2 Chemical shifts ( $\delta$ , ppm) for protons in the Xaa<sup>1</sup> alkyl side chain and chemical shift perturbations,  $\Delta \delta_{(Xb-Xa)}$  (ppm) and  $\Delta \delta_{(Xc-Xa)}$  (ppm), in CH<sub>3</sub>CN- $d_3$  solution at 298 K

cells, as described previously with some modification.<sup>31,32</sup> These results are listed in Table 4 along with previously obtained data for 1a and 1c. From the earlier results, it was concluded that the square form exhibits cytotoxicity and that the cytotoxicity is lessened by folding.4-8 Among Xa peptides, 3a and 4a, which have negative  $\Delta G_{298K}^{\circ}$  values, exhibited little or no cytotoxicity. Among Xb peptides, 1b, 3b and 4b exhibited stronger cytotoxicity than the corresponding **Xa** peptides. The  $\Delta G_{298K}^{\circ}$  value of **1b** was equal to that of 1a, but the cytotoxicity of 1b was 7 times that of **1a**. Furthermore, despite having a negative  $\Delta G_{298\text{K}}^{\circ}$  value, 3b and 4b exhibited about 2-3 times stronger cytotoxicity than the parent peptide 1a. Although the conformation and stability were very similar between the Xa and Xb peptides, there were significant differences in cytotoxicity. Xc peptides, which assume the most stable square forms, exhibited stronger cytotoxicity than the corresponding Xa peptides. However, the cytotoxicities of the Xb peptides were equal to or greater than those of the Xc peptides, except for 2b.

Conclusion

Paper

Our conformational studies carried out both in crystal and in solution, showed that incorporation of a Chg<sup>5</sup> residue does not affect the conformational equilibrium but incorporation of Phg<sup>5</sup> residue strongly promotes stabilization of the square form. It is considered that a  $CH\cdots\pi$  interaction between the side chains of the Xaa<sup>1</sup> and Phg<sup>5</sup> residues is a key factor stabilizing the square form of Xc peptides. The thermodynamic parameters estimated through NMR-based quantification provided strong evidences for this suggestion. The highly positive  $\Delta G^{\circ}$  values in the conformational equilibrium of Xc peptides mean no spontaneous folding. The  $\Delta H^{\circ}$  values for the folding process of **Xc** peptides were estimated to be 5-8 kJ mol<sup>-1</sup> higher than those for the corresponding Xa and Xb peptides. These enthalpic losses are relevant to the  $CH\cdots\pi$  interaction energies, which must be disrupted during the folding of Xc peptides. Stabilization of the square form by the  $CH\cdots\pi$  interaction also resulted in increased cytotoxicity.

# **Experimental**

# Peptide syntheses

The Thz unit (Boc-D-Val(Thz)-OMe) was synthesized as previously described.32,33 The linear peptide Boc-Xaa-allo-Thr-D-Val-Thz-Yaa-allo-Thr-D-Val-Thz-OMe was synthesized using 1hydroxybenzotriazole (Watanabe Chemical Ind. Ltd, Hiroshima, Japan) and 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide hydrochloride (Watanabe Chemical Ind. Ltd, Hiroshima, Japan) in a liquid phase. Macrocyclization was accomplished using benzotriazolyloxy-tris(pyrrolidino)phosphonium fluorophosphate (Watanabe Chemical Ind. Ltd, Hiroshima, Japan) in the presence of 4-dimethylaminopyridine (Nacalai Tesque, Kyoto, Japan). The Oxz rings were formed by reacting the Xaa-allo-Thr and Yaa-allo-Thr moieties with bis(2methoxyethyl)aminosulfur trifluoride (Deoxo-Fluor) (Fujifilm Wako Pure Chemical Corp., Osaka, Japan).34 The synthesis and characterization of  $X\mathbf{b}$  (X = 2-4) and  $X\mathbf{c}$  (X = 2-4) are detailed in the ESI.†

## X-ray diffraction

Peptides **2b** and **2c** were crystallized from *N,N*-dimethylacetamide (DMA). X-ray diffraction data for **2b** was collected with a Rigaku CrysAlis Pro (Rigaku Corp., Tokyo, Japan). X-ray diffraction data for **2c** was collected with a Bruker Smart APEXII (Bruker Corp., Massachusetts, USA). The structures of **2b** and **2c** were solved using SHELXS-97 (ref. 35) and refined using SHELXL-97.<sup>35</sup> The crystal data for both have been deposited with the Cambridge Crystallographic Data Center under deposition numbers 2191404 and 2191405, respectively. The crystal data for the two peptides are given in ESI.†

### Circular dichroism

CD spectra were obtained using a JASCO spectra-polarimeter (model J-820, JASCO, Tokyo, Japan) with a 1 cm quartz cell at room temperature. The spectra were scanned in the range of

200-280 nm at a speed of 5 nm min<sup>-1</sup> with a 0.1 nm interval for uptake to a computer. Data were averaged over each 1 nm and plotted. The spectra were measured in acetonitrile (CH<sub>3</sub>CN) solution while changing the 2,2,2-trifluoroethanol (TFE) concentration (10%, 20%, 30%, 40% and 50%). Peptide concentrations were about 0.04 mM.

### <sup>1</sup>H NMR

 $^{1}$ H NMR spectra were recorded on an Agilent DD2 600 MHz NMR spectrometer (Agilent Technologies, California, USA). Peptide concentrations were about 5.0 mM in CH<sub>3</sub>CN- $d_3$ . Chemical shifts were measured relative to internal tetramethylsilane at 0.00 ppm. The protons were assigned using two-dimensional correlated spectroscopy (2D-COSY) and rotating-frame Overhauser effect spectroscopy (ROESY; mixing time = 500 ms). VT- $^{1}$ H NMR measurements were made every 10 K from 273 K to 333 K. The assignment lists and 1D, 2D-COSY and ROESY spectra for X**b** (X = 2–4) and X**c** (X = 2–4) are given in ESI. $^{\dagger}$ 

### NMR-based quantitative studies

The conformational equilibrium constants (K) (Fig. 2) of the peptides were determined as previously described.<sup>8</sup> The behaviors of the chemical shifts of conformationally sensitive Thz protons are the focus of this method. When the Thz rings face each other in the folded form, the chemical shifts for the Thz<sup>4</sup> and Thz<sup>8</sup> protons appear in a higher magnetic field than those in the square form due to the ring-current effects of the Thz<sup>8</sup> and Thz<sup>4</sup> rings, respectively. The K values of the peptides were estimated using eqn (1),

$$K = (\delta_{\rm S} - \delta_{\rm obs})/(\delta_{\rm obs} - \delta_{\rm F}) \tag{1}$$

where  $\delta_{\rm obs}$  is the chemical shift of the Thz protons in the equilibrating peptide,  $\delta_{\rm S}$  (=8.09 ppm) is the chemical shift of the Thz protons in T3ASC,<sup>36</sup> and  $\delta_{\rm F}$  (=7.35 ppm) is the chemical shift of the Thz protons in dASC.<sup>37</sup> Two peptides, T3ASC and dASC, were used as reference peptides to provide reference chemical shifts for the fully square and folded forms, respectively. The chemical structures of T3ASC and dASC are given in ESI.†

The enthalpy  $(\Delta H^{\circ})$  and entropy  $(\Delta S^{\circ})$  were determined through a linear van't Hoff plot ( $\ln K versus \ 1/T$ ), after which the Gibbs free energy ( $\Delta G^{\circ}$ ) at 298 K was calculated using eqn (2).

$$\Delta G^{\circ} = \Delta H^{\circ} - T \Delta S^{\circ} = -RT \ln K \tag{2}$$

### Assay for cytotoxicity

The cytotoxicity of the peptides was assessed using the 3-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyl-2H-tetrazolium bromide (MTT) method as described previously with some modifications.  $^{38,39}$  HL-60 human myeloblastic leukemia cells were cultured in RPMI 1640 medium (10% fetal calf serum) at 37 °C under 5% CO<sub>2</sub>. The test materials were dissolved in dimethyl

sulfoxide to a concentration of 10 mM, after which that stock solution was diluted with essential medium to concentrations of 200, 20 and 2 µM. Each solution was combined with cells suspended (1  $\times$  10<sup>5</sup> cells per mL) in the same medium. After incubating at 37 °C for 72 h under 5% CO<sub>2</sub>, the cells were labeled with 5 mg mL<sup>-1</sup> MTT in phosphate-buffered saline (PBS), and the absorbance of formazan dissolved in 20% sodium dodecyl sulfate in 0.1 N HCl was measured at 540 nm with a microplate reader (MTP-310, Corona electric Co. Ltd, Hitachinaka, Japan). The absorbance values are expressed as percentages relative to that of a control cell suspension prepared using the same procedure described above but without a test substance. All assays were performed three times, semilogarithmic plots were constructed from the averaged data, and the effective dose of a substance required to inhibit cell growth by 50% (ED<sub>50</sub>) was determined.
