# Organic binary charge-transfer compounds of 2,2':6',2'':6'',6-trioxotriphenylamine and a pyrene-annulated azaacene as donors†

 Rajorshi Das,<sup>a</sup> Michael Linseis,<sup>a</sup> Stefan M. Schupp,<sup>b</sup> Franciska S. Gogesch,<sup>a</sup> Lukas Schmidt-Mende <sup>b</sup> and Rainer F. Winter <sup>\*a</sup>

Three binary charge-transfer (CT) compounds resulting from the donor 2,2':6',2'':6'',6-trioxotriphenylamine (TOTA) and the acceptors F<sub>4</sub>TCNQ and F<sub>4</sub>BQ and of a pyrene-annulated azaacene (PAA) with the acceptor F<sub>4</sub>TCNQ are reported. The identity of these CT compounds are confirmed by single-crystal X-ray diffraction as well as by IR, UV-vis-NIR and EPR spectroscopy. X-ray diffraction analysis reveals a 1:1 stoichiometry for TOTA·F<sub>4</sub>TCNQ, a 2:1 donor:acceptor ratio in (TOTA)<sub>2</sub>·F<sub>4</sub>BQ, and a rare 4:1 stoichiometry in (PAA)<sub>4</sub>·F<sub>4</sub>TCNQ, respectively. Metrical parameters of the donor (D) and acceptor (A) constituents as well as IR spectra indicate full CT in TOTA·F<sub>4</sub>TCNQ, partial CT in (TOTA)<sub>2</sub>·F<sub>4</sub>BQ and only a very modest one in (PAA)<sub>4</sub>·F<sub>4</sub>TCNQ. Intricate packing motifs are present in the crystal lattice with encaged,  $\pi$ -stacked (F<sub>4</sub>TCNQ<sup>-</sup>)<sub>2</sub> dimers in TOTA·F<sub>4</sub>TCNQ or mixed D/A stacks in the other two compounds. Their solid-state UV-vis-NIR spectra feature CT transitions. The CT compounds with F<sub>4</sub>TCNQ are electrical insulators, while (TOTA)<sub>2</sub>·F<sub>4</sub>BQ is weakly conducting.

## Introduction

Ever since the first report on the charge-transfer compound TTF<sup>+</sup>·TCNQ<sup>-</sup> (TTF = tetrathiafulvalene, TCNQ = tetracyanoquinodimethane) with metal-like conductivity,<sup>1</sup> organic charge-transfer (CT) systems D <sup>$\delta$ +</sup>·A <sup>$\delta$ -</sup>, composed of a donor (D) and an acceptor (A), have attracted a great deal of attention.<sup>2-6</sup> Compounds of this type can act as good electrical conductors or components of ambipolar semiconductors<sup>3</sup> and may show other intriguing properties including strong electron-phonon coupling,<sup>7,8</sup> photoelectricity,<sup>9-13</sup> ferromagnetism,<sup>14</sup> antiferromagnetism,<sup>15</sup> or luminescence.<sup>16-19</sup> The degree of charge-transfer between the D and A components tends to increase with a decreasing energy difference between the lowest unoccupied molecular orbital LUMO of the acceptor A and the highest occupied molecular orbital HOMO of the donor D. Such information can be retrieved by quantum chemical calculations<sup>20</sup> or, on an experimental basis, from their electrochemical reduction or oxidation potentials, respectively.<sup>3</sup> These data therefore provide useful guidelines to adjust the likely degree of CT and aid in the purposeful design of CT compounds. For

example, the combination of a strong donor with a strong acceptor usually leads to the formation of a CT compound D<sup>+</sup>·A<sup>-</sup> with a full transfer of charge (type-I, Fig. 1). This class of compounds may show strong ferromagnetism, but is often associated with only poor charge-transport capabilities.<sup>15,21,22</sup>

The properties of D-A-based CT compounds do, however, not only depend on the degree of charge-transfer, but also on the stoichiometric ratio D:A and on intermolecular D/D, A/A and D/A interactions in the crystal lattice. The various modes

† Electronic supplementary information (ESI) available. CCDC 2220394, 2220397 and 2220398. For ESI and crystallographic data in CIF or other electronic format see DOI: <https://doi.org/10.1039/d2ra07322f>

of  $\pi$ -stacking play a particularly important role in this respect.<sup>3–5</sup> From the wealth of previous studies it has emerged that D–A based CT compounds where the donors and the acceptors form segregated stacks (motif II in Fig. 2) show often higher charge mobilities than CT compounds where the donors and the acceptors form alternating (1:1 ratio) or mixed stacks ( $n:1$  ratios) (motif I in Fig. 2). Illustrative examples are provided by various CT compounds assembled from TTF or its derivatives and TCNQ that crystallize in segregated D and A stacks and show conductivities of as high as 200 to 1000 S cm<sup>-1</sup>.<sup>3,21</sup> In contrast, CT compounds of tetramethoxyselenanthrenes and TCNQ form an alternately mixed-stacked structure [D...A]<sub>∞</sub> of type A–I and exhibit poor conductivities of 4 × 10<sup>-10</sup> S cm<sup>-1</sup>.<sup>3,21</sup>

In this work, we have studied D–A compounds formed by combining the donors 2,2':6',2'':6'',6-trioxotriphenylamine (TOTA, Fig. 3) and a pyrene-annulated azaacene (PAA) with five different acceptors, namely the 2,3,5,6-tetrahalogeno-*p*-benzoquinones X<sub>4</sub>BQ (X = F, Cl, Br), 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F<sub>4</sub>TCNQ) and 7,7,8,8-tetracyanoquinodimethane (TCNQ). The donors constitute extended, planar  $\pi$ -systems and hence should be well-suited for  $\pi$ -stacking,<sup>23–25</sup> but also allow for interdonor hydrogen bonding involving the O or N heteroatoms and for C≡N or C–F  $\pi$ -hole tetrel interactions.<sup>26–30</sup> TOTA is a nonplanar, electron-rich molecule with a low half-wave potential  $E_{1/2}^{0/+}$  of 110 mV (in CH<sub>2</sub>Cl<sub>2</sub>/NBu<sub>4</sub>PF<sub>6</sub> against the ferrocene/ferrocenium standard couple FcH/FcH<sup>+</sup> = 0 mV) for its first one-electron oxidation. In contrast, PAA shows its first oxidation potential at  $E_{ox}^{0/+}$  = 1205 mV under the same experimental conditions and is hence a much weaker donor (Table 1, *vide infra*). The acceptors were

Fig. 3 The donors and acceptors used in this study.

chosen in order to cover a wider range of half-wave potentials for their first one-electron reduction, ranging from  $E_{1/2}^{0/-}$  = 153 mV for F<sub>4</sub>TCNQ to –464 mV for Cl<sub>4</sub>BQ in the order F<sub>4</sub>TCNQ > TCNQ > F<sub>4</sub>BQ ≈ Cl<sub>4</sub>BQ ≈ Br<sub>4</sub>BQ (Table 1). We show that the degree of CT in the TOTA compounds varies considerably from the strong acceptor F<sub>4</sub>TCNQ to the weaker acceptor F<sub>4</sub>BQ as it is, *inter alia*, manifested by a structural change of the TOTA donor from bowl-shaped to planar with an increasing degree of CT. Almost no CT to F<sub>4</sub>TCNQ was observed for the CT compound with the weaker PAA donor.

## Results and discussion

### Synthesis of the charge-transfer compounds

The D–A compounds formed on dissolving equimolar quantities of the respective pair of a donor and an acceptor in CH<sub>2</sub>Cl<sub>2</sub> in a small vial. The vial was loosely capped by a screwcap and the solvent was allowed to slowly evaporate. After one or two weeks, dark purple crystals of a CT compound of TOTA and F<sub>4</sub>TCNQ, dark orange crystals of a TOTA/F<sub>4</sub>BQ and dark green crystals of a PAA/F<sub>4</sub>TCNQ D–A compound were obtained. Other

combinations of one of these donors and another acceptor as well as using toluene as the solvent did not result in crystalline or phase-pure materials, although the formation of some pale-greenish crystals of a CT adduct of TOTA and TCNQ and of few yellow-green crystals from the PAA/TCNQ mixture were observed. These crystals did however not diffract well and could not be isolated in sufficient quantities and purity from the cocrystallized donor or acceptor to allow for their further investigation. Photographs of the three CT compounds discussed in this study and their precursors are provided in Fig. S1 in the ESI.†

As discussed in the introduction, the electron donating and accepting abilities of all donors and acceptors were investigated by cyclic voltammetry. Representative cyclic voltammograms are provided in Fig. S2 to S4 in the ESI†; relevant data are listed in Table 1.

### The TOTA-based CT compounds $(\text{TOTA})_2 \cdot (\text{F}_4\text{TCNQ})_2 \cdot \text{CH}_2\text{Cl}_2$ and $(\text{TOTA})_2 \cdot (\text{F}_4\text{BQ})$

2,2':6',2'':6'',6-Trioxotriphenylamine (TOTA) is slightly bowl-shaped and can be easily oxidized to a stable, planar radical cation.<sup>31,32</sup> Its first oxidation potential  $E_{1/2}^{0/+}$  of 110 mV against the ferrocene/ferrocenium standard (FcH/FcH<sup>+</sup>) in  $\text{CH}_2\text{Cl}_2/\text{Bu}_4\text{PF}_6$  (<sup>n</sup>Bu<sub>4</sub>PF<sub>6</sub> = tetrabutylammonium hexafluorophosphate) is close to the reported value of 140 mV in DMF.<sup>31</sup> Its reaction with equimolar quantities of the strong acceptor F<sub>4</sub>TCNQ accordingly yielded the 1:1 salt  $(\text{TOTA})_2 \cdot (\text{F}_4\text{TCNQ})_2 \cdot \text{CH}_2\text{Cl}_2$  with an essentially full transfer of charge between the donor and the acceptor (*vide infra*). The compound crystallized in the monoclinic space group  $P2_1/c$  with two crystallographically distinct molecules of the donor and the acceptor each and one  $\text{CH}_2\text{Cl}_2$  solvent molecule in the unit cell. The structure is shown in Fig. 4.

The bond parameters of F<sub>4</sub>TCNQ and, to a lesser extent, of TOTA are sensitive to their oxidation state. Neutral F<sub>4</sub>TCNQ has a quinoid structure with pronounced short-long-short bond length alternation (see Fig. 3 and Table 2). One-electron reduction increases the aromaticity of the central ring and renders the intracyclic CC bonds more similar while

lengthening the exocyclic C=C bonds. This bond lengthening appears to constitute the most indicative structure change in tetracyanoquinodimethanes concomitant with reduction, which complies with the notion that the cyano groups are the primary electron acceptors.<sup>46–48</sup> On the other hand, bond length changes on oxidation of TOTA are diluted over the entire polycyclic  $\pi$ -system so that the most indicative structural changes are the shortening of the N–C bonds and the flattening of the cone at the amine N atom from 10° to fully planar (see Fig. 5).

Fig. 5 X-ray structures and metric parameters of (a) neutral TOTA,<sup>31</sup> (b) the TOTA constituent in  $(\text{TOTA})_2 \cdot \text{F}_4\text{BQ}$  and (c) the TOTA<sup>+</sup> cation.

Table 2 summarizes pertinent bond lengths of reference compounds  $F_4TCNQ$ ,  $F_4TCNQ^-$ , TOTA,  $TOTA^+$ ,  $F_4BQ$ ,  $Cl_4BQ$ ,  $Cl_4BQ^-$  and the D–A compounds of the present study. As can be seen from the data in Table 2, the metrics of the TOTA and the  $F_4TCNQ$  constituents in  $(TOTA)_2 \cdot (F_4TCNQ)_2 \cdot CH_2Cl_2$  agree with those of the  $TOTA^+$  cation in the  $PF_6^-$ ,  $ClO_4^-$  and  $ReO_4^-$  salts and of the  $F_4TCNQ^-$  anion in  $NBu_4^+ F_4TCNQ^-$ , respectively.<sup>37,38</sup> In particular, the TOTA constituent has completely flattened out (Fig. 5c). This characterizes  $(TOTA)_2 \cdot (F_4TCNQ)_2 \cdot CH_2Cl_2$  as a true CT salt with full ionicity.

In the crystal lattice, the  $F_4TCNQ^-$  anions associate to pairs of nearly parallel, eclipsed molecules with a tilt angle of  $1.60^\circ$  between their ring planes and a rather small interplanar distance of  $3.215 \text{ \AA}$  (Fig. 4 and 6). The formation of  $F_nTCNQ^-$  ( $n = 0, 4$ ) dimers has been observed on previous occasions and is associated with an antiferromagnetic alignment of their unpaired spins.<sup>38,49–51</sup> Individual  $(F_4TCNQ^-)_2$  dimers are separated by two  $CH_2Cl_2$  solvent molecules and arrange in columns that run parallel to the  $a$  axis of the unit cell.  $F_4TCNQ^-$  ions of neighbouring columns are nearly coplanar with a modest tilt of their ring planes by  $6.7^\circ$  and rotated by almost  $90^\circ$ .

The  $F_4TCNQ^-$  columns are separated by sheets that are formed by surrounding  $TOTA^+$  cations. Like the  $F_4TCNQ^-$  anions,  $TOTA^+$  polycycles that belong to different sheets adopt nearly orthogonal orientations with interplanar angles of  $85.8^\circ$  and  $88.0^\circ$  between their ring planes. As is shown in Fig. 4b, the  $F_4TCNQ^-$  dimers are engaged by six  $TOTA^+$  cations and every  $TOTA^+$  cation is in turn surrounded by three  $F_4TCNQ^-$  dimers. This rather curious packing arrangement is established by various  $C \equiv N \cdots$  and  $C-F \cdots \pi$ -hole tetrel bonds<sup>26–30</sup> as well as by  $C-H \cdots N \equiv C$  hydrogen bonds and one weak  $CH \cdots F$  interaction of  $2.640 \text{ \AA}$ . Fig. 6 provides a view of two neighbouring  $(F_4TCNQ^-)_2(TOTA^+)_6$  cages with two additional weakly associated  $TOTA^+$  cations and the ensuing network of noncovalent interactions. The  $C \equiv N \cdots \pi$ -hole tetrel interactions range from  $2.998$

$\text{\AA}$  to  $3.183 \text{ \AA}$ , while the  $C-F \cdots \pi$ -hole contacts measure  $2.977 \text{ \AA}$  to  $3.136 \text{ \AA}$ ;  $CH \cdots N$  interactions cover a range from  $2.500 \text{ \AA}$  to  $2.701 \text{ \AA}$ . Adjacent cages weakly associate by pairwise  $CH \cdots O$  contacts of  $2.697 \text{ \AA}$  between parallel displaced and laterally offset  $TOTA^+$  cations. When viewed along the  $b$ -axis of the unit cell (see the horizontal rows in Fig. 4b), an alternating arrangement of  $(F_4TCNQ^-)_2$   $\pi$ -dimers and two coplanar  $TOTA^+$  cations emerges. The  $D^+ \cdots D^+$   $\pi$ - $\pi$  interactions of  $3.388$ – $3.445 \text{ \AA}$  are notably weaker than the  $A^- \cdots A^-$   $\pi$ - $\pi$  interactions of  $3.108$ – $3.195 \text{ \AA}$  (Fig. 4 and 6).

Single crystals of  $(TOTA)_2 \cdot F_4BQ$  were grown by slow evaporation of a  $CH_2Cl_2$  solution of their equimolar mixture. The asymmetric unit cell contains one TOTA donor molecule and half a  $F_4BQ$  acceptor molecule. In the crystal lattice, each  $F_4BQ$  acceptor molecule is surrounded by two slightly bowl-shaped TOTA donors to provide a centrosymmetric arrangement  $D \cdots A \cdots D$  of nearly coplanar TOTA and  $F_4BQ$  molecules with interplanar angles of  $3.6^\circ$  between their planes as defined by the three oxygen atoms at the TOTA ether straps or the central  $C_6$  ring of  $F_4BQ$ . The N atom of the TOTA donor is displaced by  $0.25 \text{ \AA}$  from the TOTA ring plane and points towards the  $F_4BQ$  acceptor to provide a  $N \cdots F_4BQ_{\text{centr.}}$  distance of  $2.851 \text{ \AA}$ . These  $D \cdots A \cdots D$  arrays stack into infinite columns that run along the  $c$ -axis of the unit cell. Fig. 7b provides a view of two such  $D \cdots A \cdots D$  triples; an extended view over several unit cells down the  $c$  axis can be found as Fig. S5 of the ESI.† Neighbouring donors have an interplanar distance of  $3.791 \text{ \AA}$  between the centroids as defined by their oxygen atoms and form pairwise contacts  $C5 \cdots C15$  of  $3.238 \text{ \AA}$ . Within the  $ab$ -plane of the unit cell, every  $F_4BQ$  acceptor associates with six coplanarly arranged TOTA donors through a total of eight  $C-F \cdots H-C$  hydrogen bonds of  $2.485 \text{ \AA}$  to  $2.643 \text{ \AA}$  and four  $O \cdots H-C$  hydrogen bonds of  $2.567 \text{ \AA}$  and  $2.614 \text{ \AA}$ , respectively (see Fig. S6 of the ESI†). The TOTA molecules that surround the  $F_4BQ$  acceptors connect through pairwise  $O \cdots H-C$  hydrogen bonds of  $2.656 \text{ \AA}$ , respectively. In turn, every TOTA molecule is surrounded by alternately arranged TOTA donors

Fig. 6 Intermolecular  $\pi$ -stacking,  $C \equiv N \cdots$  and  $C-F \cdots \pi$ -hole tetrel and H-bonding interactions in  $(TOTA)_2 \cdot (F_4TCNQ)_2 \cdot CH_2Cl_2$ , distances shorter than the sum of the van der Waals radii are indicated by blue dotted lines.

Fig. 7 X-ray molecular structure of  $(TOTA)_2 \cdot F_4BQ$ . (a) Packing diagram within the  $ab$  plane with intermolecular H-bonding interactions indicated by blue dotted lines. (b) One-dimensional  $[D \cdots A \cdots D]_\infty$  columns that run along the  $c$  axis of the unit cell. Colour codes: H, white; C, grey; N, blue; F, yellow-green; O, red.

and  $F_4BQ$  acceptors. Fig. 7a provides a view of the molecule arrangement and the resulting H-bonding network.

The bonding parameters of both, the  $F_4BQ$  acceptor and the TOTA donor argue for an only limited degree of charge transfer, but do not allow for a quantitative assessment. Since no X-ray data for an authenticated  $F_4BQ^-$  anion seem to be available in the literature, we resort to its chloro-substituted analogue  $Cl_4BQ^{n-}$  ( $n = 0, 1$ ) for comparison.<sup>43</sup> One-electron reduction of  $Cl_4BQ$  causes a lengthening of the intracycle C=C bonds and, by a larger margin, the external C=O bonds while the former C-C bonds contract. The bond parameters of the  $F_4BQ$  constituent of  $(TOTA)_2 \cdot F_4BQ$  are close to that of  $F_4BQ$  itself or to those of its 1 : 1 TTF or its 1 : 2 TMIQ CT compounds, which also show only a fair degree of CT (TMIQ represents the 1,4-phenylene-bridged ditopic bis-carbazole donor shown on the right of the header of Table 2).<sup>44,45</sup> In further agreement with an only modest degree of CT, the donor constituents retain the domed, non-planar structure of neutral TOTA, albeit with a smaller cone angle of  $7.5^\circ$  at the N atom and slightly wider  $C_{ph}-N-C_{ph}$  bond angles  $\alpha$ ,  $\beta$ , and  $\gamma$  of  $116.57(10)^\circ$ ,  $116.86(10)^\circ$  and  $117.00(10)^\circ$  as compared to the values of  $115.3(2)^\circ$ ,  $115.6(2)^\circ$  and  $115.7(2)^\circ$  for neutral TOTA (Fig. 5).<sup>31</sup> As already mentioned,  $TOTA^+$  is planar with angles  $\alpha$ ,  $\beta$ , and  $\gamma$  close to  $120^\circ$  (e.g.  $119.7(5)^\circ$ ,  $119.9(5)^\circ$  and  $120.3(5)^\circ$  in the perchlorate salt).<sup>27</sup> The  $N-C_{phenyl}$  and  $O-C_{phenyl}$  bond lengths in  $(TOTA)_2 \cdot F_4BQ$  are nearly identical to those of pristine, neutral TOTA and significantly longer than in  $(TOTA)_2 \cdot (F_4TCNQ)_2 \cdot CH_2Cl_2$  or other salts with authenticated  $TOTA^+$  cations.<sup>31,32</sup>

### The donor-acceptor compound $(PAA)_4 \cdot F_4TCNQ$

As suggested by the high anodic peak potential of 1205 mV, the pyrene-annulated azaacene PAA (Fig. 3) is only a very poor donor. Hence, the formation of a binary D-A compound was only observed with the strongest acceptor  $F_4TCNQ$ . The dark green crystals obtained by slow evaporation of  $CH_2Cl_2$  from a 1 : 1 solution of PAA and  $F_4TCNQ$  turned out to assume a rather unusual 4 : 1 D : A stoichiometry  $(PAA)_4 \cdot F_4TCNQ$ . The compound crystallized in the monoclinic space group  $C2/c$ . The asymmetric unit consists of two molecules of the PAA donor and half a molecule of the  $F_4TCNQ$  acceptor. In the crystal lattice, repeat units of four D and one A molecules form one-dimensional infinite columns  $[\cdots D \cdots D \cdots A \cdots D \cdots D \cdots]_\infty$  that run along alternately the  $a$  or the  $b$  axis of the unit cell (Fig. 8). The neighbouring, crystallographically unique PAA donors PAA1 and PAA2 of an  $A \cdots D \cdots D \cdots$  sequence align in a quasi-centrosymmetric fashion in order to minimize steric repulsion between the bulky trimethylsilyl substituents. As is shown in the left panel of Fig. 8, these building blocks repeat in a centrosymmetric manner to generate columns. With interplane angles  $F_4TCNQ$ -PAA1 of  $2.30^\circ$  and PAA1-PAA2 of  $1.96^\circ$ , the individual donor and the acceptor molecules arrange in a nearly coplanar fashion. Separations of  $3.324 \text{ \AA}$  ( $F_4TCNQ$ -PAA1),  $3.328 \text{ \AA}$  (PAA1-PAA2) and  $3.378 \text{ \AA}$  (PAA2-PAA2) are all smaller than  $3.5 \text{ \AA}$ , which indicates  $\pi$ -stacking interactions.<sup>52</sup>

The close match between the bond lengths of the A constituent of this compound to those of neutral  $F_4TCNQ$  evidences

Fig. 8 (a) Molecular packing of  $(PAA)_4 \cdot F_4TCNQ$  viewed along the  $a$  axis of the unit cell. (b) Alignment of the rows in the crystal lattice. Solvent molecules are removed for clarity reasons.

the lack of any substantial degree of CT from PAA. The bonding parameters of the crystallographically distinct PAA donors in  $(PAA)_4 \cdot F_4TCNQ$  differ slightly (see Fig. S7 of the ESI†), but are in line with those in neutral, pyrene- appended azaacene derivatives and other bis(trimethylsilyl) derivatives of diethynyl-substituted azaacenes.<sup>23,24</sup>

As a bottom line, crystallographic data indicate full CT in  $(TOTA)_2 \cdot (F_4TCNQ)_2$ , an only moderate degree of CT in  $(TOTA)_2 \cdot F_4BQ$ , and the absence of any significant degree of CT in  $(PAA)_4 \cdot F_4TCNQ$ , which complies with the difference of oxidation potentials of the respective donor and the reduction potential of the acceptor.

### IR, UV-vis-NIR and EPR spectroscopy

In addition to structure data, infrared (IR) and UV-vis-NIR spectroscopy have proven highly instructive for quantifying the extent of charge-transfer in D-A compounds. Of particular diagnostic value are the redox state-dependent band positions of the nitrile  $C \equiv N \tilde{\nu}(CN)$  or the quinone  $C=O$  stretching modes  $\tilde{\nu}(CO)$  of the acceptor. Their shift with respect to the neutral and the reduced forms of the respective acceptor scales linearly with the fraction of charge  $\rho$  (in units of the elementary charge  $e$ ) transferred from the donor to the acceptor.<sup>53,54</sup> These band shifts provide a widely applied criterion for assessing the degree of CT.<sup>6,21,55-60</sup> Arene stretching and bending vibrations of the D component may provide additional information.

The CN stretches of the  $F_4TCNQ$  acceptor in  $TOTA \cdot F_4TCNQ$  at  $\tilde{\nu} = 2196 \text{ cm}^{-1}$  and  $2176 \text{ cm}^{-1}$  are significantly red-shifted from their positions of  $2227 \text{ cm}^{-1}$  (the stronger  $b_{1u}$  mode) and  $2212 \text{ cm}^{-1}$  (the weaker  $b_{2u}$  mode) in pristine  $F_4TCNQ$  (Fig. 9a)<sup>61</sup> and closely resemble those of the  $F_4TCNQ^-$  anion of  $2194 \text{ cm}^{-1}$  and  $2172 \text{ cm}^{-1}$ .<sup>6,61,62</sup> The degree of charge-transfer  $\rho$  to  $F_4TCNQ$  can be calculated according to eqn (1),

$$\rho = (2 \cdot \Delta\tilde{\nu}/\tilde{\nu}_0) \cdot (1 - \tilde{\nu}_{-1}^2/\tilde{\nu}_0^2)^{-1} \quad (\text{ref. 6 and 54}) \quad (1)$$

where  $\tilde{\nu}_0$  and  $\tilde{\nu}_{-1}$  represent the wavenumber of the more prominent  $C \equiv N$  stretching vibration in neutral  $F_4TCNQ$  ( $\tilde{\nu}_0$ ) or its associated radical anion ( $\tilde{\nu}_{-1}$ ), and  $\Delta\tilde{\nu}$  is the difference between

Fig. 9 Spectroscopic changes in the mid IR region (C≡N stretching vibrations) of  $F_4TCNQ$  in (a)  $(TOTA)_2 \cdot (F_4TCNQ)_2 \cdot CH_2Cl_2$ , (b)  $(TOTA)_2 \cdot F_4BQ$ , and (c)  $(PAA)_4 \cdot F_4TCNQ$ .

the band position in neutral  $F_4TCNQ$  and the charge transfer compound,  $\tilde{\nu}_0 - \tilde{\nu}_{CT}$ , respectively. Applying eqn (1) to  $TOTA \cdot F_4TCNQ$  yields  $\rho = 0.95$  in agreement with essentially full electron transfer. IR data for the D constituent agree with this view. Hence, IR(KBr) spectra of  $TOTA \cdot F_4TCNQ$  feature donor bands at 1590, 1334, 1277, 1074 and  $1031 \text{ cm}^{-1}$  (see Fig. S8 of the ESI†). These values are nearly identical to those of 1589, 1333, 1275, 1072 and  $1028 \text{ cm}^{-1}$  reported in the literature for the  $TOTA^+$  radical cation and differ from those of pristine TOTA ( $1621, 1480, 1336, 1318, 1265, 1067$  and  $1018 \text{ cm}^{-1}$ ).<sup>63</sup>

The formation of D–A compounds is also evident from UV-vis-NIR spectroscopy. UV-vis-NIR spectra of solid samples of neutral TOTA and  $F_4TCNQ$  and of the CT compound  $TOTA \cdot F_4TCNQ$  were recorded in an integrating sphere in order to diminish intensity losses due to scattering and reflection. As shown in Fig. 10, the spectra of the neutral precursors display intense bands at 380 and 525 nm and 405 and 455 nm, respectively, whereas  $TOTA \cdot F_4TCNQ$  shows discernible peaks at 595, 650, 770 and at *ca.* 1060 nm.

EPR spectroscopy provides a highly sensitive probe of paramagnetic species resulting from charge transfer.<sup>62,64,65</sup> Solid

Fig. 10 Monitoring the CT compound formation by UV-vis-NIR spectroscopy. The spectra of CT compounds are plotted with their parent donor and acceptor constituents. (a)  $(TOTA)_2 \cdot (F_4TCNQ)_2 \cdot CH_2Cl_2$  and (b)  $(PAA)_4 \cdot F_4TCNQ$ .

$TOTA \cdot F_4TCNQ$  (Fig. 11a) shows accordingly an intense EPR resonance at a  $g$  value of 1.9990, whose intensity increases on cooling. This agrees with the  $T$ -dependent Boltzmann distribution as given in eqn (2)<sup>66,67</sup> and the high ionicity in the ground state of this compound. One should note here that the observed EPR resonance in the solid state is likely due to exclusively the  $TOTA^+$  cation, as the  $F_4TCNQ^-$  anions associate to diamagnetic dimers.

$$\Delta N \approx N \cdot \frac{g \cdot \mu_B \cdot B_0}{2k_B T} \quad (2)$$

For  $F_4BQ$ , the energies of the  $\nu(CO)$  stretching vibrations serve the same purpose as the CN bands in  $X_nTCNQ$  derivatives ( $X = \text{Hal}$ ,  $n = 0-4$ ) such that eqn (1) applies accordingly.  $\nu_{CO}$  bands of  $F_4BQ$  in  $(TOTA)_2 \cdot F_4BQ$  are found at 1665 and  $1648 \text{ cm}^{-1}$ , whereas they are located at 1702, 1691 and  $1678 \text{ cm}^{-1}$  in neutral  $F_4BQ$  (see Fig. 9b). The data are to be compared with literature values of 1705, 1693 and  $1686 \text{ cm}^{-1}$  for  $F_4BQ$ <sup>68</sup> and 1556 and  $1502 \text{ cm}^{-1}$  for the sodium salt of  $F_4BQ^-$ .<sup>69,70</sup> Using eqn (1),  $\rho$  was calculated as 0.26. Hence,  $(TOTA)_2 \cdot F_4BQ$  seems to exhibit a fair degree of CT which was not so evident from the structure data. There are only minor shifts in the IR bands of the TOTA constituents (Fig. S9 of the ESI†). One should, however, note that the extent of charge loss from an individual TOTA donor is only half of that which is accumulated at the  $F_4BQ$  acceptor. In the solid state,  $(TOTA)_2 \cdot F_4BQ$  exhibits a weak, broad CT absorption at low energy (Fig. S10 of the ESI†). As shown in Fig. 11b, solid  $TOTA \cdot F_4BQ$  is also EPR active, but shows an opposite  $T$  dependence to  $TOTA \cdot F_4TCNQ$ , i. e. the signal intensity decreases on lowering the temperature. This suggests that CT in these compounds is a thermally activated process. In summary, IR, UV-vis-NIR and EPR data on the solid samples are consistent with the notion of (nearly) quantitative CT from the donor to the acceptor in  $TOTA \cdot F_4TCNQ$  and a more modest one in  $(TOTA)_2 \cdot F_4BQ$ . The degree of CT  $\rho$  as quantified by the shift of the C≡N stretching vibrations of the donor amounts to 0.95 and 0.26, respectively.

In contrast, the IR data of  $(PAA)_4(F_4TCNQ)$  resemble those of the pristine, neutral constituents closely with only a small shift of the  $\nu_{CN}$  band by *ca.*  $1.5 \text{ cm}^{-1}$  (Fig. 9c) which translates into  $\rho \approx 0.05$ , thus indicating a very modest degree of CT (see also Fig. S11 of the ESI† for the arene bands). In agreement with the small degree of CT,  $(PAA)_4(F_4TCNQ)$  shows only a very weak EPR

Fig. 11  $T$ -dependent EPR spectra of the CT compounds  $TOTA \cdot F_4TCNQ$  (left) and  $(TOTA)_2 \cdot F_4BQ$  (right).

resonance signal (see Fig. S12 of the ESI†). Nevertheless, the compound absorbs strongly in the solid state over the entire UV and vis range down to 1100 nm as shown in Fig. 10b. We note that accounts of compounds showing prominent CT bands despite small degrees of CT have appeared in the literature.<sup>19</sup>

In order to assess their conductive properties, single crystals of all three isolated CT compounds were placed on a gold plate or a conductive Cu-tape and contacted with two closely spaced nanoprobe, which served as electrodes (for details to the experimental setup, see the Materials and methods section and Fig. S13 of the ESI†). Even on applying a maximum voltage of 20 V, no detectable current flow was observed for TOTA·F<sub>4</sub>TCNQ and for (PAA)<sub>4</sub>·F<sub>4</sub>TCNQ, even at a tip distance as small as *ca.* 10 μm. Their insulating behaviour (Fig. S14 and S15 of the ESI†) is a direct consequence of their structures with very weakly interacting (TOTA)<sup>+</sup><sub>8</sub>(F<sub>4</sub>TCNQ<sup>-</sup>)<sub>2</sub> cages or [··D··D··A··D··D··]<sub>∞</sub> columns with negligible charge transfer. (TOTA)<sub>2</sub>·F<sub>4</sub>BQ is also nearly insulating with a resistance per unit length of 5–10 GΩ μm<sup>-1</sup> for different specimen, which is close to the detection limit of our experimental setup (Fig. S16–S19 of the ESI†).

## Conclusions

We describe two charge-transfer compounds of the 2,2':6',2'':6''-trioxotriphenylamine donor and tetrafluoro-tetracyano-*p*-quinodimethane (F<sub>4</sub>TCNQ) or tetrafluoro-*p*-benzoquinone (F<sub>4</sub>BQ) as the acceptor component and a donor-acceptor complex of a much less electron-rich pyrene-annulated azaacene (PAA) with F<sub>4</sub>TCNQ. Although in each case equimolar amounts of the donor D and the acceptor A were used for their synthesis, only (TOTA)<sub>2</sub>·(F<sub>4</sub>TCNQ)<sub>2</sub>·CH<sub>2</sub>Cl<sub>2</sub> adopted a D:A stoichiometry of 1:1. Crystals isolated with F<sub>4</sub>BQ as the acceptor provided a 2:1 ratio between the donor and the acceptor constituents instead. The combination of PAA and F<sub>4</sub>TCNQ resulted even in a rare 4:1 composition, yielding (PAA)<sub>4</sub>·(F<sub>4</sub>TCNQ). X-ray diffraction analysis indicated full charge transfer from the donor to the acceptor in (TOTA)<sub>2</sub>·(F<sub>4</sub>TCNQ)<sub>2</sub>·CH<sub>2</sub>Cl<sub>2</sub> by virtue of the bond parameters of the F<sub>4</sub>TCNQ acceptor and the planarization of the TOTA constituent. These findings are also supported by IR and UV-vis-NIR spectroscopy. In the crystalline state, π-stacked F<sub>4</sub>TCNQ<sup>-</sup> dimers are encaged by six TOTA<sup>+</sup> counterions with only weak interactions between these structural entities.

For the other two D/A combinations, X-ray structure analysis revealed mixed stacking patterns with [D···A···D]<sub>∞</sub> or [D···D···A···D···D]<sub>∞</sub> packing motifs. Monitoring the shifts of the C≡N and C=O stretching frequencies in the CT compounds with respect to the neutral and monoreduced acceptors revealed an essentially complete charge-transfer in (TOTA)<sub>2</sub>·(F<sub>4</sub>TCNQ)<sub>2</sub>·CH<sub>2</sub>Cl<sub>2</sub>, a moderate degree of charge-transfer in (TOTA)<sub>2</sub>·(F<sub>4</sub>BQ) ( $\rho = 0.26$ ) and an only very modest degree of CT in (PAA)<sub>4</sub>·(F<sub>4</sub>TCNQ). Nevertheless, a fairly intense CT band was found in solid state UV-vis-NIR spectra. *T*-dependent EPR spectra recorded in the solid state agree with a (nearly) complete CT in the ground state of the TOTA·F<sub>4</sub>TCNQ compound, while CT in (TOTA)<sub>2</sub>·(F<sub>4</sub>BQ) is thermally activated and (PAA)<sub>4</sub>·(F<sub>4</sub>TCNQ) shows only a very weak EPR signal. All CT compounds are non-conductive or, in the case of (TOTA)<sub>2</sub>·(F<sub>4</sub>BQ) very weakly conductive in the solid state.

## Data availability

Details to the methods and materials, characterization data and additional figures can be found in the ESI†. CCDC reference numbers for the reported crystallographic structures are 2220394 ((PAA)<sub>4</sub>·F<sub>4</sub>TCNQ), 2220397 ((TOTA)<sub>2</sub>·F<sub>4</sub>BQ) and 2220398 ((TOTA)<sub>2</sub>·(F<sub>4</sub>TCNQ)<sub>2</sub>·CH<sub>2</sub>Cl<sub>2</sub>).
