# Magnetic clusters and ferromagnetic spin glass in the novel hexagonal perovskite 12R-Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub>†

Xiaohui Yan,<sup>a</sup> Junkun Wu,<sup>a</sup> Xiuyun Lei,<sup>\*a</sup> Lunhua He,<sup>bcd</sup> Wenbin Guo,<sup>\*a</sup> Xiaojun Kuang<sup>ib</sup> and Congling Yin<sup>ib</sup> <sup>\*,a</sup>

A 12-layer hexagonal perovskite Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> (space group:  $R\bar{3}m$ ;  $a = 5.72733(3)$  Å, and  $c = 28.1770(3)$  Å) has been synthesized by high-temperature solid-state reactions and studied using powder X-ray and neutron diffraction and magnetization measurements. This 12R polytype structure contains one corner-sharing (Sb, Mn)O<sub>6</sub> octahedron and a trimer of face-sharing MnO<sub>6</sub> octahedra per formula unit. Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> displays a paramagnetic state of the Mn<sub>3</sub> magnetic cluster at 100–200 K, which partially disassociates into individual Mn ions at 250–300 K. The ferromagnetic interaction between these Mn<sub>3</sub> clusters is mainly mediated by Mn<sup>3+</sup> at the M1 site, leading to dynamic ferromagnetic clusters below  $T_D = \sim 70$  K and ferromagnetic spin freezing transition at  $T_g = \sim 11.5$  K. The stability of Mn<sub>3</sub> magnetic clusters in the 12R polytypes is related to the intracluster Mn–Mn distance.

## 1 Introduction

Manganese oxides have been the focus of materials research for many decades owing to their technological applications as heterogeneous catalysts,<sup>1</sup> Li-ion batteries,<sup>2,3</sup> SOFC electrode materials,<sup>4</sup> CMR materials,<sup>5</sup> and quantum materials.<sup>6,7</sup> This has motivated the investigation of the hexagonal perovskite BaMnO<sub>3-δ</sub> system, which shows a diversity of crystal structures and magnetic properties.<sup>8–12</sup> A series of BaMnO<sub>3-δ</sub> polytypes (2H → 15R → 8H → 6H → 10H → 4H) have been found as the oxygen vacancy concentration  $\delta$  increases.<sup>8,11</sup> Further perovskite polytypes may be produced when Mn and Ba are replaced by other cations.

Many Mn-substituted BaM<sub>x</sub>Mn<sub>1-x</sub>O<sub>3</sub> systems have been investigated, for instance, with M = Ca,<sup>13</sup> In,<sup>14,15</sup> Sn,<sup>16,17</sup> Sb,<sup>18</sup> Ti,<sup>19</sup> Fe,<sup>20</sup> Ru,<sup>21</sup> Ir,<sup>22</sup> Nb,<sup>23</sup> and rare earth Ln.<sup>24–26</sup> This led to the discovery of a series of M-cation ordered 12R perovskites Ba<sub>4</sub>M<sub>1+x</sub>Mn<sub>3-x</sub>O<sub>12</sub> (M = Ti<sup>4+</sup> and Sn<sup>4+</sup>),<sup>17,19</sup> Ba<sub>4</sub>MMn<sub>3</sub>O<sub>11.5</sub> (M = In<sup>3+</sup> and Y<sup>3+</sup>)<sup>14,27</sup> and Ba<sub>4</sub>MMn<sub>3</sub>O<sub>12</sub> (M = Nb<sup>5+</sup>, Ce<sup>4+</sup>, and Pr<sup>4+</sup>).<sup>23,26</sup>

The 12R perovskite Ba<sub>4</sub>MMn<sub>3</sub>O<sub>12</sub> contains close-packed BaO<sub>3</sub> layers in a (cchh)<sub>3</sub> sequence and accommodates the M and Mn ions in the corner-sharing octahedral centre M1 and face-sharing octahedral centres M2 and M3 respectively (Fig. 1a). Partial disorder of M and Mn elements occurs on the M2 site in case of M = Ti<sup>4+</sup> and Sn<sup>4+</sup>,<sup>17,19</sup> and oxygen vacancies are present for the M = In<sup>3+</sup> and Y<sup>3+</sup> case.<sup>14,27</sup>

Polymorphs of BaMnO<sub>3-δ</sub> have long-range antiferromagnetic (AFM) order of all the Mn spins, with  $T_N = 220$ –270 K.<sup>10,11</sup> However, the long-range magnetic order is suppressed in the 12R perovskites upon low-level nonmagnetic doping, and the substituted M ions plays a key role in the magnetic behaviour of these materials. Ba<sub>4</sub>YMn<sub>3</sub>O<sub>11.5</sub>,<sup>27</sup> Ba<sub>4</sub>Sn<sub>1.1</sub>Mn<sub>2.9</sub>O<sub>12</sub> (ref. 17) and Ba<sub>4</sub>CeMn<sub>3</sub>O<sub>12</sub> (ref. 24) undergo an AFM transition at  $T_N = 4$ –6 K, while Ba<sub>4</sub>InMn<sub>3</sub>O<sub>11.5</sub> (ref. 14) and Ba<sub>4</sub>Ti<sub>2</sub>Mn<sub>2</sub>O<sub>12</sub> (ref. 19) display

Fig. 1 The crystal structures of (a) 12R Ba<sub>4</sub>MMn<sub>3</sub>O<sub>12</sub> and (b) 10H Ba<sub>5</sub>MMn<sub>4</sub>O<sub>15</sub> viewed along [110], showing the stacking sequence of BaO<sub>3</sub> and corner-sharing octahedron center M1 and face-sharing octahedron center M2 and M3. Color code: barium (green sphere), M (orange sphere), manganese (purple sphere), oxygen (red sphere), MnO<sub>6</sub> (purple octahedron), and MO<sub>6</sub> (orange octahedron).

no magnetic order, and  $\text{Ba}_4\text{NbMn}_3\text{O}_{12}$  shows a ferrimagnetic transition at  $T_C = 42$  K (ref. 23) (Table S1†). Furthermore, the Nb, Ti and Sn-doped 12R polytype show meta-magnetism, with linear  $\text{Mn}_3$  magnetic clusters arranged in a triangular lattice, leading to magnetic frustrations.<sup>17,23,28</sup> Therefore, the 12R perovskite materials are potential quantum materials, such as quantum spin liquid and spin ice. The exploration of new 12R perovskite  $\text{BaM}_x\text{Mn}_{1-x}\text{O}_3$  is of great concern.

In the  $\text{BaSb}_{1-x}\text{Mn}_x\text{O}_3$  system, two perovskite polymorphs 6H  $\text{Ba}_3\text{MnSb}_2\text{O}_9$  (ref. 29) and 10H  $\text{Ba}_5\text{Sb}_{1-x}\text{Mn}_{4+x}\text{O}_{15-\delta}$  have been identified. The  $\text{Ba}_5\text{Sb}_{1-x}\text{Mn}_{4+x}\text{O}_{15-\delta}$  has close-packed  $\text{BaO}_3$  layers in  $(\text{cchhh})_2$  sequences and features tetramers of face-sharing  $\text{MnO}_6$  octahedra (Fig. 1b).<sup>18</sup> Regarding the close relationship between the 10H and 12R polymorphs, one wonders whether the 12R perovskites  $\text{BaSb}_{1-x}\text{Mn}_x\text{O}_3$  can exist. If the 12R  $\text{BaSb}_{1-x}\text{Mn}_x\text{O}_3$  is stabilized, it would be a good material with magnetic clusters and frustration. Motivated by such ideas, we started a series of investigations on the  $\text{BaSb}_{1-x}\text{Mn}_x\text{O}_3$  materials. Herein we report the synthesis, crystal structure, and magnetic properties of 12R  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  perovskite.

## 2 Experimental

### 2.1 Synthesis

The polycrystalline  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  was synthesized from  $\text{BaCO}_3$  (99.5%, Aladdin),  $\text{MnCO}_3$  (99.95%, Aladdin), and  $\text{Sb}_2\text{O}_3$  (99.9%, Aladdin) reagents with solid-state reaction methods. These starting materials were thoroughly mixed with alcohol in an agate mortar and pestle and heated in a platinum crucible at 1173 K for 10 hours to decompose the carbonates. The materials were then reground, pressed into pellets ( $20 \text{ ton cm}^{-2}$ ), placed on platinum crucibles, and sintered at 1573 K for 36 hours with heating and cooling rates of  $5 \text{ K min}^{-1}$ . At several intermediate steps, the materials were re-ground and re-pressed, and powder X-ray diffraction (XRD) was performed at each step to follow the reaction to completion.

### 2.2 Characterization

The phase purity of the samples was characterized by XRD using a PANalytical X'Pert Pro powder diffractometer with  $\text{Cu K}\alpha$  radiation at 40 kV and 40 mA. High-quality XRD data were collected on the  $2\theta$  range  $5\text{--}120^\circ$  at room temperature (RT) for Rietveld analysis carried out using the Topas Academic software.<sup>30</sup> Bond valence sum (BVS) was calculated using standard parameters with Brown and Altermatt's method.<sup>31</sup> Low-temperature XRD data were collected in the  $5\text{--}298$  K range with an interval of 10 K, using a Rigaku SmartLab X-ray diffractometer with  $\text{Cu K}\alpha$  radiation at 45 kV and 200 mA.

Time of flight (TOF) neutron powder diffraction (NPD) data were collected from a 5 g powder sample of  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  using the General-Purpose Powder Diffractometer (GPPD) at the China Scattering Neutron Source (CSNS, Dongguan, China). Scanning electron microscopy (SEM) imaging and X-ray energy dispersive spectroscopy (EDS) elemental analysis were carried out using a GeminiSEM 300 (ZEISS, Germany) scanning

electron microscope with an Ultim Max (Oxford, U.K.) EDS spectrometer.

Magnetic measurements were performed on Quantum Design's MPMS-3 Superconducting Quantum Interference Device (SQUID) magnetometer. Direct-current (dc) magnetic susceptibility was recorded in a magnetic field of 1000 Oe while heating the sample from 2 K to 300 K after zero-field cooling (ZFC) and field cooling (FC). Alternating-current (ac) magnetization was measured with an ac amplitude of  $\mu_0 h_{ac} = 10$  Oe at frequencies of  $3 \leq f \leq 250$  Hz in the temperature range  $5\text{--}15$  K. Isothermal field-dependent magnetization was performed at the applied field from  $-6$  to 6 T and temperature of 2 K, 5 K, 15 K, 20 K, 30 K, 40 K, 50 K, 60 K and 100 K.

## 3 Results and discussions

### 3.1 Phase formation

The initial  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  samples consisted of mixed 12R perovskite phase and Mn-rich phases such as 8H  $\text{BaMnO}_{3-\delta}$  (marked with asterisks), due to the loss of antimony oxides during the sintering process (melting point of  $\text{Sb}_2\text{O}_5$  and  $\text{Sb}_2\text{O}_3$  are  $\sim 655$  K and  $\sim 928$  K).<sup>32</sup> The Mn-rich phase was reduced through extra Sb doping. The 12R perovskite phase was isolated as a single phase at the nominal composition of  $\text{Ba}_4\text{Sb}_{1.03}\text{Mn}_3\text{O}_{12}$ , while beyond this Sb doping level other impurity reflections were observed, as marked as arrows in Fig. 2.

The chemical composition of the nominal  $\text{Ba}_4\text{Sb}_{1.03}\text{Mn}_3\text{O}_{12}$  sample is most likely to be consistent with the stoichiometric perovskite of  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$ , which is reasonably supported by the Ba : Sb : Mn ratio of  $4.00(20) : 1.01(4) : 2.73(12)$  from the EDS elemental analysis (Fig. 3) and the following Rietveld refinements.

### 3.2 Crystal structure

The light oxygen atoms are not well located with X-ray diffraction in the presence of heavy elements such as barium. Neutron diffraction (ND) is more sensitive to oxygen because the neutron

Fig. 2 XRD patterns of nominal  $\text{Ba}_4\text{Sb}_{1+x}\text{Mn}_3\text{O}_{12}$  samples, showing a pure phase 12R perovskite at the  $x = 0.03$  composition. The reflection from  $\text{BaMnO}_{3-\delta}$  polymorphs and other impurities are marked with asterisks and arrows, respectively.

Fig. 3 SEM image and EDS elemental mapping image on the  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  sample, indicating the homogeneous distribution of elements.

scattering length of oxygen (5.083 fm) is comparable to that of Ba (5.07 fm).<sup>33</sup> Therefore, to find the accurate oxygen position, neutron diffraction data were collected on the  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  sample. The Rietveld refinements against the XRD and NPD data simultaneously were performed, based on the structural model of 12R  $\text{Ba}_4\text{NbMn}_3\text{O}_{12}$  (Fig. 1a). During the refinements, the lattice parameters, the atomic coordinates, and the thermal

Fig. 4 Rietveld refinement plots of (a) XRD data and (b) ND data for the  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  sample, showing observed (red crosses), calculated (green line), and difference curve (grey line). The reflection positions for  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  are marked with blue bars in both plots.

displacement parameters (Beq) were varied freely. Anisotropic peak broadening was described with the Stephens model. In the first step, the occupancies of Sb and Mn at M1, M2, and M3 sites were refined with the total occupancies on each site subject to unity. A negative value of Sb on the M3 site was found, excluding the presence of Sb at the M3 site. In the following refinement, the occupancies of Sb and Mn were refined only at M1 and M2 sites, with the total ratio of Sb : Mn constrained as 1 : 3. In the second step, the oxygen occupancies were refined, and no vacancies were found at the oxygen sites within the refinement error. Therefore, the occupancies at both O1 and O2 sites were set as unity. The final refinement rapidly converged at the  $R_{\text{wp}}$  parameters of 5.50% and 4.32% for XRD and NPD data respectively (Fig. 4a and b). The refined structural parameters and selected bond distances and angles are summarized in Tables 1 and 2.

In the crystal structure of 12R  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$ , Sb and Mn atoms are mixed on two crystallographic independent sites M1 and M2, with occupancy of 84% Sb/16% Mn and 8% Sb/92% Mn respectively. The BVS results listed in Table 1 show that the formal Mn charges are segregated, with  $\text{Sb}^{5+}$  and  $\text{Mn}^{3+}$  (which have similar ionic radii of 0.60 and 0.645 Å (ref. 34) respectively) at the corner-sharing M1 site, mixed  $\text{Mn}^{3+}$ ,  $\text{Mn}^{4+}$  and  $\text{Sb}^{5+}$  at the M2 site, and  $\text{Mn}^{4+}$  at the M3 site. Based on the charge neutrality, this corresponds to the chemical formula  $\text{Ba}_4(\text{Sb}_{1.084}^{5+}\text{Mn}_{0.163+})_2(\text{Sb}_{0.08}^{5+}\text{Mn}_{2.042}^{3+}\text{Mn}_{0.54+})_2(\text{Mn}^{3+})\text{O}_{12}$ , where Mn1 corresponds to Mn at site M1, etc. This chemical formula has an average charge of Mn2 of +3.54, essentially identical to the BVS of 3.47.

The cationic distributions in  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  are different from those of the Sn, Y, and Nb-analogue.<sup>17,23,27,35</sup> In  $\text{Ba}_4\text{Sn}_{1.1}\text{Mn}_{2.9}\text{O}_{12}$ ,  $\text{Sn}^{4+}$  and  $\text{Mn}^{4+}$  are mixed on the corner-sharing M1 (Sn : Mn ratio of 0.88 : 0.12) and face-sharing M2 (Sn : Mn ratio of 0.11 : 0.89) sites.<sup>17</sup> In  $\text{Ba}_4\text{YMn}_3\text{O}_{11.5}$  and  $\text{Ba}_4\text{NbMn}_3\text{O}_{12}$ , the substituted  $\text{Y}^{3+}/\text{Nb}^{5+}$  and  $\text{Mn}^{4+}$  (and  $\text{Mn}^{3+}$ ) ions are well separated over the M1 and M2 sites respectively. The structure of

(Mn/Sb) <sub>M2</sub> –O2 (×3) 1.953 (2)		

Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> contains a higher proportion of magnetic Mn<sup>3+</sup> cations (~16%) at the M1 sites that interconnect the Mn<sub>3</sub>O<sub>12</sub> trimers of face-sharing octahedra, which has a strong impact on the magnetic properties as discussed in the following sections.

It should be noted about the distortion of the outer MnO<sub>6</sub> octahedra in the trimers. The Mn<sub>M2</sub> atom shifts toward the c-BaO<sub>3</sub> layers, forming three short Mn–O bonds (~1.95 Å) and three long ones (~1.97 Å), while the inner Mn<sub>M3</sub>O<sub>6</sub> octahedron has no distortion constrained by its local site symmetry (*D*<sub>3d</sub>). This leads to a short Mn–Mn distance *d*<sub>Mn–Mn</sub> of ~2.5 Å inside the Mn<sub>3</sub>O<sub>12</sub> trimer, which is comparable with that in the elemental α-Mn.<sup>36</sup> This phenomenon could indicate a degree of d-orbital overlap between neighboring Mn ions forming Mn<sub>3</sub> magnetic clusters.

Phase stability of Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> was investigated by low-temperature XRD (Fig. 5a). No phase transition was observed in the range of 5–298 K. The lattice parameters and cell volume keep constant below ~70 K and increase linearly as temperature increases above 70 K, showing thermal expansion coefficient of  $\alpha_a = 7.9 \times 10^{-6} \text{ K}^{-1}$ ,  $\alpha_c = 7.0 \times 10^{-6} \text{ K}^{-1}$  and  $\alpha_V = 2.2 \times 10^{-5} \text{ K}^{-1}$ .

### 3.3 Magnetic properties

The dc magnetization data for Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> (Fig. 6a) were corrected against two background terms: the susceptibility of the capsule determined as  $-5.6 \times 10^{-6} \text{ emu}$  with a blank measurement, and the diamagnetic susceptibility of

Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub>, which can be estimated as  $-2.91 \times 10^{-4} \text{ emu f.u.}^{-1}$  (or equally  $-1.00 \times 10^{-4} \text{ emu per mol Mn}^{4+}$ ) using Pascal's constant.<sup>37</sup> The susceptibilities are nearly constant above 150 K and increase as the temperature goes down, which is typical for localized spin systems. A broad peak in magnetic susceptibilities ( $\chi_{dc}$ ) appears at around *T*<sub>m</sub> = 10.5 K, indicating a magnetic phase transition. Ferromagnetic components are present below *T*<sub>C</sub> as suggested by the divergent ZFC and FC susceptibilities.

The susceptibilities between 100 and 200 K can be well fitted based on the equation  $\chi = C/(T - \theta)$ , yielding the Weiss temperature  $\theta_{cw}$  of ~43.4 K and *C* ~ 1.16 emu K mol<sup>-1</sup> (Fig. 6b). This corresponds to a paramagnetic moment  $\mu_{eff}$  of ~3.05  $\mu_B$  per mol Mn or ~5.28  $\mu_B$  per mol Mn<sub>3</sub> cluster. The former is significantly smaller than the expected value of 4.24  $\mu_B$  calculated from spin only Mn<sup>3+</sup>:Mn<sup>4+</sup> moment in the proportion 1 : 2, and this contradicts the paramagnetic states of individual Mn spins. The latter value is essentially identical to the expected values of ~4.89  $\mu_B$ , as estimated with the most possible Mn<sub>3</sub> cluster of Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> containing one terminal Mn<sup>3+</sup> and two Mn<sup>4+</sup> ions (Fig. 6b inset). This observation indicates the stabilization of Mn<sub>3</sub> magnetic clusters in a paramagnetic state at 100–200 K. Ferro- or ferri-magnetic interactions occur between the Mn<sub>3</sub> clusters as indicated by the positive  $\theta_{cw}$  ~ 43.4 K.

The Curie–Weiss fits of magnetic susceptibility at 250–300 K range leads to an  $\mu_{eff} = 3.45(1) \mu_B$  per mol Mn or  $\mu_{eff} = 5.98 \mu_B$  per mol Mn<sub>3</sub> cluster equally. This result is larger than the expected value of Mn<sub>3</sub> clusters and smaller than that of Mn ions. This phenomenon indicates the Mn<sub>3</sub> magnetic cluster is partially destroyed, leading to the coexistence of individual Mn ions and Mn<sub>3</sub> clusters in this temperature range, although an exclusively paramagnetic state of Mn ions requires a higher temperature.

Similar Mn<sub>3</sub> magnetic clusters have been evidenced with different stability in 12R Sn- and Nb-doped analogs.<sup>17,23</sup> Compared with that in Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> (*d*<sub>Mn–Mn</sub> = ~2.506 Å), the Mn<sub>3</sub> cluster in Ba<sub>4</sub>NbMn<sub>3</sub>O<sub>12</sub> (*d*<sub>Mn–Mn</sub> = ~2.469 Å) is more stable without dissociation at RT,<sup>23</sup> while the Mn<sub>3</sub> cluster in Ba<sub>4</sub>Sn<sub>1.1</sub>Mn<sub>2.9</sub>O<sub>12</sub> (*d*<sub>Mn–Mn</sub> = ~2.523 Å) is unstable at RT and split into Mn ions.<sup>17</sup> The stability of Mn<sub>3</sub> clusters can be associated with the intra-cluster *d*<sub>Mn–Mn</sub>. A smaller Mn–Mn distance would mediate stronger direct exchange interactions *via* a greater overlap between the *t*<sub>2g</sub> orbitals of Mn ions, leading to greater stability of Mn<sub>3</sub> clusters in these 12R perovskites.

Isothermal *M*–*H* data were performed at 2–100 K to study the magnetic ground states of Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> (Fig. 7a). Linear *M*–*H* dependence at 100 K is consistent with the paramagnetic states of Mn<sub>3</sub> clusters. Magnetic hysteresis and saturation are observed at 2–60 K. In contrast with the isotropic magnetization at 15–60 K, small magnetic anisotropy is observed with a coercive field of 100 mT and 12 mT at 2 K and 5 K respectively. This indicates Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> displays a ferro- or ferri-magnetic state below 60 K. The saturated moment *M*<sub>s</sub> can be estimated with the intercept from the linear *M*–*H* fit at the high field range. Being a constant of ~1.61  $\mu_B$  at 2–5 K, the *M*<sub>s</sub> decreases linearly at increasing temperatures above *T*<sub>C</sub> and disappears at *T*<sub>D</sub> ~ 70 K from extrapolation (Fig. 7b). Here, *T*<sub>D</sub> represents the

Fig. 5 Temperature-dependent (a) XRD data for Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> and (b) cell parameters relative to the 5 K values (*a*<sub>0</sub> = 5.72318(9) Å, *c*<sub>0</sub> = 28.1536(6) Å, *V*<sub>0</sub> = 798.62(3) Å<sup>3</sup>), with the fits shown as the solid lines.

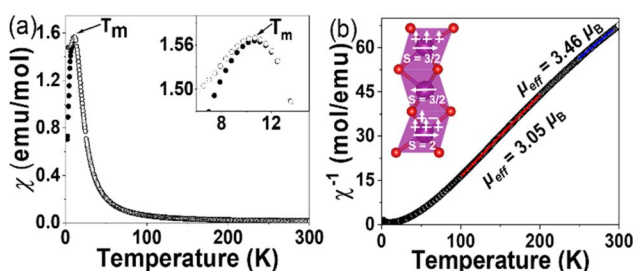

Fig. 6 (a) ZFC (filled circles) and FC (empty circles) magnetic susceptibility for Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub> per mol Mn, with low-temperature data shown in the inset. (b) Inverse magnetic susceptibilities. The red and blue lines show the linear fits on 100–200 K and 250–300 K, corresponding to  $\mu_{eff} = 3.05$  and  $3.46 \mu_B$  per mol Mn. The inset to (b) shows the schematics of the most possible arrangements of Mn<sup>3+</sup> and Mn<sup>4+</sup> in the Mn<sub>3</sub> magnetic clusters of Ba<sub>4</sub>SbMn<sub>3</sub>O<sub>12</sub>.

Fig. 7 (a) Magnetization of  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  from  $-6$  T to  $6$  T at various temperatures. The inset expands the  $M$ - $H$  curves at the low-field region. (b) The saturated moment  $M_s$ , with the variation trends shown in dashed lines.

temperature dynamical ferromagnetic clusters initially form, while  $T_C$  represents the spin-freezing temperature. This critical linear behavior is different from the saturation behavior in typical long-range ferromagnet  $\text{SrFe}_{0.5}\text{Co}_{0.5}\text{O}_3$ ,<sup>38</sup> and indicates the nature of ferromagnetic spin glass.<sup>39</sup> The  $T_D/T_C$  of about  $6$  keeps with those observed in other spin glass systems.<sup>40,41</sup>

The spin-glass behavior is further studied by the ac susceptibility, and the real (and imaginary) component of the ac susceptibility  $\chi'$  (and  $\chi''$ ) versus temperature at different frequencies is plotted in Fig. 8 (and Fig. S1†). The peak in dc susceptibility at  $T_m \approx 10.5$  K appears to be a frequency-dependent peak in the ac susceptibilities. The temperature  $T_m$  at the broad peak maximum shifts to higher values as the frequency increases (Fig. 8 bottom inset). The frequency dependence of  $T_m$  can be well fitted to a critical power law (Fig. 8 top inset),<sup>41,42</sup> with the best power-law fit,

$$\tau = \tau_0 \left( \frac{T_m}{T_g} - 1 \right)^{-z\nu}$$

where  $\tau = (2\pi f)^{-1}$ ,  $\tau_0$  is the average relation time and  $T_g$  is the static glassy transition temperature, and  $z\nu$  is the dynamic

Fig. 8 Temperature dependence of the real ac susceptibility component  $\chi'$  at frequencies of  $3 \leq f \leq 250$  Hz. The bottom inset shows the data around  $T_m$  for clarity. The top inset shows the frequency dependence of the freezing temperature  $T_m$  with the best power-law fit.

critical exponent. The fitted  $T_g = 11.6(3)$  K is close to the  $T_m$  in dc susceptibilities. The  $\tau_0 = 10^{-8.3(6)}$  s keeps with the fitted characteristic relation time of  $10^{-8}$  to  $10^{-12}$  s for canonical spin glass,<sup>41–43</sup> while the  $z\nu = 3.5(7)$  is also comparable to that in typical spin glass materials.

Another important factor for characterizing a magnetic glassy transition is the frequency shift  $K$ , which gives a relative variation in the peak temperature  $T_m$  with the angular frequency and is defined as follows:

$$K = \frac{1}{T_m} \frac{\Delta T_m}{\Delta \log \omega}$$

The frequency shift  $K$  on  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  is estimated to be about  $0.016$ , much smaller than the values for superparamagnets and close to those observed in spin glasses. This indicates the magnetic state of  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  is a spin glass rather than a superparamagnet.

The magnetic saturation and frustration blew  $T_C$  may arise from the partial occupancy of  $\text{Mn}^{3+}$  at the M1 sites, as observed in  $\text{Ba}_5\text{Sb}_{1-x}\text{Mn}_{4+x}\text{O}_{15-\delta}$  systems.<sup>18</sup> The dominant magnetic super-exchange interactions between  $\text{Mn}_3$  magnetic clusters are associated with the near-linear M1–O–M2 connections in the 12R structure type (see Table 2). The hexagonal average lattice symmetry is incompatible with long-range orbital order, but when  $\text{Mn}^{3+}$  ions are present at the M1 sites, local orbital order concerning the  $\text{Mn}^{3+}$  and  $\text{Mn}^{4+}$  ions at the six neighboring M2 sites is likely in such a highly connected manganite network. This gives rise to a mixture of strong ferromagnetic  $\text{Mn}_{\text{M1}}^{3+}$ –O– $\text{Mn}_{\text{M2}}^{4+}$  and antiferromagnetic  $\text{Mn}_{\text{M1}}^{3+}$ –O– $\text{Mn}_{\text{M2}}^{3+}$  interactions (both types are found in long-range orbitally ordered and spin-ordered manganites such as  $\text{La}_{0.5}\text{Ca}_{0.5}\text{MnO}_3$  and  $\text{LaMnO}_3$  (ref. 44)).

According to the  $\text{Sb}_{\text{M1}}^{5+}:\text{Mn}_{\text{M1}}^{3+}$  ratio of  $\sim 5.25$ , we can assume each  $\text{Mn}_3$  trimer connects with six  $\text{Sb}^{5+}$  or five  $\text{Sb}^{5+}$  and one  $\text{Mn}^{3+}$  on the adjacent M1 site, while each  $\text{Mn}_{\text{M1}}^{3+}$  has six  $\text{Mn}_3$  trimers as neighbors. As a result, about 96% of  $\text{Mn}_3$  clusters assemble into isolated superclusters of  $(\text{Mn}_3)_6\text{Mn}^{3+}$  via  $\text{Mn}^{3+}$  on the M1 site, while minor ( $\sim 4\%$ )  $\text{Mn}_3$  clusters are isolated with six adjacent  $\text{Sb}^{5+}$  ions. The local  $(\text{Mn}_3)_6\text{Mn}^{3+}$  supercluster possesses three kinds of  $\text{Mn}_{\text{M2}}^{4+}$ –O– $\text{Mn}_{\text{M1}}^{3+}$ –O– $\text{Mn}_{\text{M2}}^{4+}$  linear bridge related to the charge state of terminal Mn ions. The charge symmetric bridges  $\text{Mn}_{\text{M2}}^{4+}$ –O– $\text{Mn}_{\text{M1}}^{3+}$ –O– $\text{Mn}_{\text{M2}}^{4+}$  and  $\text{Mn}_{\text{M2}}^{3+}$ –O– $\text{Mn}_{\text{M1}}^{3+}$ –O– $\text{Mn}_{\text{M2}}^{3+}$  would mediate a parallel alignment between  $\text{Mn}_3$  clusters spins, while the charge asymmetric bridge  $\text{Mn}_{\text{M2}}^{3+}$ –O– $\text{Mn}_{\text{M1}}^{3+}$ –O– $\text{Mn}_{\text{M2}}^{4+}$  would lead to an antiparallel alignment. As  $\text{Sb}^{5+}$ ,  $\text{Mn}^{3+}$ , and  $\text{Mn}^{4+}$  mixes on the M2 site at the ratio of  $0.08 : 0.42 : 0.5$  (see Table 1), the  $\text{Mn}_{\text{M2}}^{3+}$ –O– $\text{Mn}_{\text{M1}}^{3+}$ –O– $\text{Mn}_{\text{M2}}^{3+}$  bridges in the  $(\text{Mn}_3)_6\text{Mn}^{3+}$  supercluster consist of 42.64% charge-symmetric, 42% charge-asymmetric, and 15.36% diamagnetic  $\text{Sb}^{5+}$  ions containing ones. Therefore, these charge-symmetric  $\text{Mn}_{\text{M2}}^{4+}$ –O– $\text{Mn}_{\text{M1}}^{3+}$ –O– $\text{Mn}_{\text{M2}}^{4+}$  bridges would mediate 40.9% of all  $\text{Mn}_3$  cluster spins frozen in a parallel arrangement in the magnetic ground state of 12R  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$ , and leads to expected saturated moments of  $1.63\mu_B$ , which is essentially identical with the observed  $M_s$  of  $1.61\mu_B$  at 2–5 K.

The presence of a significant proportion of  $\text{Mn}^{3+}$  at the M1 sites in  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  appears to be essential for the pronounced ferromagnetism. This can be indicated by  $\text{Ba}_4\text{Sn}_{1.1}\text{Mn}_{2.9}\text{O}_{12}$ , which hosts  $\text{Mn}^{4+}$  and  $\text{Sn}^{4+}$  on the M1 site and displays weak ferromagnetism with  $M_s$  of  $\sim 0.09\mu_B$  at 2 K. Compared with the magnetic  $\text{Mn}_4$  cluster with all spin canceled, the  $\text{Mn}_3$  cluster has net spins and also contributes to ferromagnetism. This explains the reduced ferromagnetism of 10H  $\text{Ba}_5\text{Sb}_{1-x}\text{Mn}_{4+x}\text{O}_{15}$  with higher content of  $\text{Mn}^{3+}$  ( $\sim 24\text{--}36\%$ ) on the M1 site compared with that of 12R  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$ . Further studies of magnetic order using theoretical calculation will be needed to account more fully for the spin ordering phenomena.

## 4 Conclusions

The new 12R perovskite  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  has been synthesized by high-temperature solid-state reactions. The material has an ordered arrangement of Sb and Mn cations, and trimers of face-sharing  $\text{MnO}_6$  octahedra. The paramagnetic state of  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  at 100–200 K can be described with the  $\text{Mn}_3$  magnetic clusters, which partially disassociate into individual Mn ions at 250–300 K. The stability of  $\text{Mn}_3$  magnetic clusters in the 12R polytypes is related to the intracluster Mn–Mn distance. The ferromagnetic interaction between these  $\text{Mn}_3$  clusters is mainly mediated by  $\text{Mn}^{3+}$  at the M1 site, leading to dynamic ferromagnetic clusters below  $T_D = \sim 70$  K and ferromagnetic spin freezing transition at  $T_g = \sim 11.5$  K.  $\text{Ba}_4\text{SbMn}_3\text{O}_{12}$  is another rare example of a periodical lattice that shows cluster magnetism due to the cationic order beyond orbital molecules.<sup>45</sup>
