Facile formation of barium titanium oxyhydride on a titanium hydride surface as an ammonia synthesis catalyst†

Yoshihiro Goto, ^{*a} Masashi Kikugawa, ^a Keisuke Kobayashi, ^b Yuichi Manaka, ^b Tetsuya Nanba, ^b Hideyuki Matsumoto, ^{bc} Mitsuru Matsumoto, ^a Masakazu Aoki^a and Haruo Imagawa ^a

Oxyhydrides are promising compounds as supports for ammonia synthesis catalysts because they suppress hydrogen poisoning on the catalyst surface and enhance the ammonia synthesis activity. Herein, we developed a facile method for preparing $\text{BaTiO}_{2.5}\text{H}_{0.5}$, a perovskite oxyhydride, on a TiH_2 surface via the conventional wet impregnation method using TiH_2 and Ba hydroxide. Scanning electron microscopy and high-angle annular dark-field scanning transmission electron microscopy observations revealed that $\text{BaTiO}_{2.5}\text{H}_{0.5}$ crystallized as nanoparticles of ca. 100–200 nm on the TiH_2 surface. The Ru-loaded catalyst Ru/ $\text{BaTiO}_{2.5}\text{H}_{0.5}$ - TiH_2 exhibited 2.46 times higher ammonia synthesis activity (3.05 mmol-NH₃ g⁻¹ h⁻¹ at 400 °C) than the benchmark Ru catalyst Ru–Cs/MgO (1.24 mmol-NH₃ g⁻¹ h⁻¹ at 400 °C) because of the suppression of hydrogen poisoning. The analysis of reaction orders showed that the effect of suppressing hydrogen poisoning on Ru/ $\text{BaTiO}_{2.5}\text{H}_{0.5}$ - TiH_2 was equivalent to that of the reported Ru/ $\text{BaTiO}_{2.5}\text{H}_{0.5}$ catalyst, thus supporting the formation of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ perovskite oxyhydride. This study demonstrated that the selection of appropriate raw materials facilitates the formation of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ oxyhydride nanoparticles on the TiH_2 surface using the conventional synthesis method.

Introduction

Ammonia (NH₃), an essential raw material in the production of agricultural fertilizers and synthetic chemicals, has recently attracted attention owing to its applicability as a hydrogen carrier or fuel.^{1,2} Ammonia is predominantly produced *via* the Haber–Bosch (HB) process, which accounts for 1–2% of the global energy demand and 2.5% of global CO₂ emissions.³ Most of the CO₂ emissions are responsible for hydrogen production processes using steam reforming (CH₄ + H₂O → CO + 3H₂) and water gas shift reactions (CO + H₂O → CO₂ + H₂). Replacing these processes with water electrolysis (2H₂O → 2H₂ + O₂) using renewable energy can significantly reduce this CO₂ emission.⁴ However, renewable electricity sources of an intermittent nature are not compatible with ammonia synthesis *via* the conventional HB process⁵ because the process is operated on large-scale and steady-state operations. On this basis, ammonia

synthesis catalysts need severe reaction conditions (at 450–600 °C and 15–40 MPa).⁵ Therefore, ammonia synthesis catalysts that work under mild conditions should be developed for ammonia synthesis using renewable electricity sources.

The rate-determining step in the synthesis of ammonia (3H₂ + N₂ → 2NH₃) is the dissociation of the N₂ triple bond (945 KJ mol⁻¹), which is the strongest bond among those in diatomic molecules.^{6,7} Supported ruthenium (Ru) catalysts are the most promising candidates for ammonia synthesis under mild conditions because optimum N₂ adsorption energy facilitates N₂ dissociation on the Ru surface.⁸ Strongly basic supports (such as CeO₂, La_{0.5}Pr_{0.5}O_{1.75}, Ba/Ce_{0.5}La_{0.5}O_{1.75}, CeO₂-PrO_x, and Ce_{0.5}La_{0.5-x}Ti_xO_{1.75+0.5x})^{9–14} further promote N₂ dissociation because the basic compounds enhance the electron transfer from the Ru metal to the antibonding orbital of N₂.¹⁵ However, hydrogen atoms generated by H₂ dissociation are often adsorbed on the active sites of the Ru surface, thereby preventing N₂ dissociation on the Ru surface.¹⁶ In recent years, oxyhydrides such as BaTiO_{3-x}H_x, BaCeO_{3-x}H_yN_z, LaH_{3-2x}O_x, GdHO, and SmHO have been reported as supports that suppress hydrogen poisoning and enhance the ammonia synthesis activity of Ru catalysts.^{17–20} Suppression of hydrogen poisoning is presumed to originate from the diffusivity of hydride (H⁻), which allows hydrogen spillover from the Ru metal to the surface of the oxyhydride supports.²¹

Transition-metal (TM) oxyhydride synthesis is generally complicated because the differences in chemical properties (such as reactivity, volatility, and ionic radius) among anions prevent different anions in an identical compound from becoming stable.²² For this reason, solid-state topochemical reactions and/or high-pressure reactions have been used to synthesize TM oxyhydrides.²² BaTiO_{3-x}H_x, which is a promising TM perovskite oxyhydride support for ammonia synthesis catalysts, cannot be prepared by simply reducing BaTiO₃ with hydrogen. However, this oxyhydride is accessible *via* a solid-state topochemical reaction involving BaTiO₃ and CaH₂ because the reaction can provide a metastable phase by exchanging the oxide (O²⁻) in BaTiO₃ with hydride (H⁻) in CaH₂ while maintaining the basic framework structure of BaTiO₃.²³ However, materials preparation using the topochemical reaction is not suitable for practical use because the reaction involves a multi-step process: (1) mixing BaTiO₃ and the moisture-sensitive CaH₂ in an inert atmosphere, (2) calcining the mixture for a week under vacuum, and (3) washing in an inert atmosphere to extract product BaTiO_{3-x}H_x by removing the residual CaH₂ and by-product CaO. The practical utility of BaTiO_{3-x}H_x may be limited by low producibility owing to the multi-step process. Thus, developing more facile, efficient ways to prepare BaTiO_{3-x}H_x is necessary to accelerate the application of BaTiO_{3-x}H_x. Moreover, the development can lead to the discovery of novel oxyhydrides.

Recently, Uchimura *et al.*²⁴ have reported the direct synthesis of BaTiO_{3-x}H_x by a mechanochemical method using BaH₂, BaO, and TiO₂ and confirmed its performance as a hydrogen-permeable electrode. However, handling in an inert atmosphere is still required because BaH₂ and BaO are sensitive to moisture. Herein, we demonstrated the synthesis of BaTiO_{3-x}H_x ($x = 0.5$), a perovskite oxyhydride, on a TiH₂ surface *via* conventional wet impregnation method using TiH₂ and Ba(OH)₂·8H₂O, which are stable in moisture and air. The obtained BaTiO_{2.5}H_{0.5} was crystallized as fine particles of 100–200 nm size that covered the TiH₂ particle surface. The Ru-loaded catalyst, Ru/BaTiO_{2.5}H_{0.5}-TiH₂, showed 2.46 times higher ammonia synthesis activity than Ru-Cs/MgO as benchmark Ru catalyst. Moreover, Ru/BaTiO_{2.5}H_{0.5}-TiH₂ suppressed hydrogen poisoning, thereby proving the formation of BaTiO_{2.5}H_{0.5} perovskite oxyhydride.

Methods

BaTiO_{2.5}H_{0.5}-TiH₂ was synthesized *via* the wet impregnation method using TiH₂ powder and Ba hydroxide solution. TiH₂ (98%, –325 mesh, Sigma-Aldrich) was impregnated with a solution containing the desired amount of Ba(OH)₂·8H₂O (98.0%, FUJIFILM Wako Chemicals) dissolved in 3 : 2 (v/v) H₂O/ethanol at 230 °C in the air, after which it was heated at 350 °C for 3 h in a 10% H₂/N₂ atmosphere. The Ba addition amounts were varied from 0–15 wt% on a Ba(OH)₂ basis. The obtained compounds are hereafter referred to as Ba(α)-TiH₂ (α : wt% of Ba(OH)₂). Reference compounds Ba(α)-TiO₂ (where α = wt% of Ba(OH)₂) were prepared using the same protocols as for Ba(α)-TiH₂, except TiO₂ (99.9%, Rutile, Sigma-Aldrich) was used

instead of TiH₂. Ba(10)-TiH₂ synthesized using Ba(CH₃COO)₂ (99.0%, FUJIFILM Wako Chemicals) or Ba(NO₃)₂ (99.0%, FUJIFILM Wako Chemicals) instead of Ba(OH)₂·8H₂O were also prepared to investigate the effect of Ba sources. Cs/MgO as a benchmark compound was prepared by impregnation using MgO (99%, Sigma-Aldrich) and Cs₂CO₃ (99.9%, Sigma-Aldrich)/ethanol solution, followed by thermal treatment at 350 °C for 3 h under 10% H₂/N₂. Ru-loaded catalysts, such as Ru/Ba(α)-TiH₂, Ru/Ba(α)-TiO₂, and Ru-Cs/MgO, were prepared by impregnation using Ru₃(CO)₁₂ (99%, Sigma-Aldrich)/tetrahydrofuran solution. The suspension was stirred for 5 h, and the solvent was subsequently evaporated at 27 °C. The obtained compound was dried at 80 °C for 16 h in the air. The Cs and Ru loading amounts were 1 wt% on a metal basis.

X-ray diffraction (XRD) patterns and were collected at room temperature using SmartLab (Rigaku) with Cu K α radiation ($\lambda = 1.54056$ Å). The obtained XRD patterns were analyzed using the JANA2006 software.²⁵ The neutron diffraction (ND) pattern was collected at room temperature using the NOVA time-of-flight (TOF) neutron diffractometer at the J-PARC facility in Japan. The obtained ND pattern was analyzed using Z-Rietveld software.²⁶ Fourier-transform infrared (FT-IR) spectra were recorded using an iS50 spectrometer (Thermo Fisher) equipped with a diffuse reflectance optics accessory. Samples were pretreated at 200 °C for 30 min in flowing He and then examined at 50 °C. Scanning electron microscopy (SEM) images were obtained using a JSM-7400F (JEOL) and a SU3500 (Hitachi) operated at 1.5 kV. High-angle annular dark-field scanning transmission electron microscopy (HAADF-STEM) and energy-dispersive X-ray spectroscopy (EDS) mapping images were obtained using a Tecnai Osiris (FEI) operated at 200 kV. X-ray photoelectron spectroscopy (XPS) was conducted on a Quantera SXM instrument (ULVAC PHI) using Al K α radiation (1486.6 eV). CO amounts adsorbed by the catalyst were estimated using a BEL-METAL-3 (MicrotracBEL). CO pulse injections (1.99% CO/He) to the samples were conducted at 50 °C after the pre-treatment at 400 °C for 2 h in 100% H₂.

The ammonia synthesis activities under ambient pressure were estimated using a fixed-bed reactor connected to mass flow controllers. A sample (0.2 g) was suspended on a bed of quartz wool in a quartz tube and preheated at 400 °C for 2 h in 75% H₂/N₂ (H₂/N₂ = 3) at a flow rate of 80 mL min⁻¹. The activity measures were conducted at 300–400 °C in 75% H₂/N₂ (H₂/N₂ = 3) at a flow rate of 80 mL min⁻¹. The ammonia concentrations in the outlet of the quartz tube were monitored by FT-IR spectroscopy and converted into ammonia synthesis rates. Reaction orders of ammonia synthesis with respect to H₂, N₂, and NH₃ were estimated using the method of Aika *et al.*²⁷

Results and discussion

The XRD patterns of Ba(α)-TiH₂ ($\alpha = 0, 1, 3, 5, 10$, and 15) predominantly showed the cubic phase of the fluorite structure ($Fm\bar{3}m$) with the lattice parameter of $a = 4.4489$ –4.4519 Å (Fig. 1). The lattice parameter matches that of the reported TiH₂ ($a = 4.4512(1)$ Å),²⁸ showing that the cubic phase is TiH₂. The XRD patterns of samples with $\alpha = 0$ and 1 only showed the

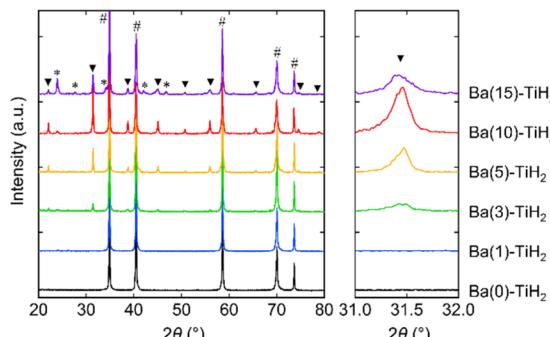

Fig. 1 XRD patterns of $\text{Ba}(\alpha)\text{-TiH}_2$ ($\alpha = 0, 1, 3, 5, 10$, and 15). Hashtags (#), triangles (▼), and asterisks (*) indicate peaks arising from TiH_2 , $\text{BaTiO}_{2.5}\text{H}_{0.5}$, and BaCO_3 , respectively.

single phase of TiH_2 , whereas the XRD patterns of $\alpha \geq 3$ samples contained an additional cubic phase of perovskite structure ($Pm\bar{3}m$; Fig. S1 in the ESI†). The lattice volume was estimated to be $V = 64.926\text{--}65.073 \text{ \AA}^3$ (Table 1), which approaches that reported for cubic $\text{BaTiO}_{2.38}\text{H}_{0.62}$ perovskite oxyhydride ($Pm\bar{3}m$, $V = 65.140 \text{ \AA}^3$)²³ rather than tetragonal BaTiO_3 perovskite oxide ($P4mm$, $V = 64.281 \text{ \AA}^3$)²⁹, which indicates that the additional cubic phase is $\text{BaTiO}_{3-x}\text{H}_x$ perovskite oxyhydride. The H content x in $\text{BaTiO}_{3-x}\text{H}_x$ ($\alpha = 3, 5, 10$, and 15) were determined to be $x = 0.47\text{--}0.57$ based on Vegard's law (Table 1; hereafter, the obtained perovskite oxyhydride is referred to as $\text{BaTiO}_{2.5}\text{H}_{0.5}$). The formation of oxygen-deficient $\text{BaTiO}_{3-\delta}$ is unlikely because the lattice volume of $\text{BaTiO}_{2.5-\delta}\text{H}_{0.5}$ ($V = 64.926\text{--}65.073 \text{ \AA}^3$) is larger than that reported for cubic $\text{BaTiO}_{3-\delta}$ perovskite oxide ($\delta = 0.25$, $Pm\bar{3}m$, $V = 64.337 \text{ \AA}^3$) where the lattice volume does not change through the formation of oxygen defects.³⁰ The formation of the $\text{BaTiO}_{3-\delta}(\text{OH})_\delta$ oxyhydroxide through OH^- incorporation is also denied because no peaks associated with OH bonds (observed at 3400 cm^{-1} in BaTiO_3 system)³¹ were observed by FT-IR spectroscopy (Fig. S2†). Moreover, the XRD patterns of the $\alpha = 10$ and 15 samples showed that BaCO_3 can potentially form through the reaction of unreacted $\text{Ba}(\text{OH})_2$ with atmospheric CO_2 absorbed during impregnation. Thus, the addition of Ba into TiH_2 forms $\text{BaTiO}_{2.5}\text{H}_{0.5}$ perovskite oxyhydride and BaCO_3 .

Table 1 Physical characteristics of $\text{Ba}(\alpha)\text{-TiH}_2$ ($\alpha = 0, 1, 3, 5, 10$, and 15)

Sample	Lattice volume of $\text{BaTiO}_{3-x}\text{H}_x$ ^a (\AA^3)	H content x ^b
$\text{Ba}(0)\text{-TiH}_2$	—	—
$\text{Ba}(1)\text{-TiH}_2$	—	—
$\text{Ba}(3)\text{-TiH}_2$	65.002(2)	0.52
$\text{Ba}(5)\text{-TiH}_2$	64.926(2)	0.47
$\text{Ba}(10)\text{-TiH}_2$	65.009(2)	0.56
$\text{Ba}(15)\text{-TiH}_2$	65.073(3)	0.57

^a Calculated from the lattice parameters based on the cubic perovskite structure ($Pm\bar{3}m$, $Z = 1$). ^b Determined from Vegard's law using the lattice volumes of BaTiO_3 ($V = 64.281 \text{ \AA}^3$)²⁹ and $\text{BaTiO}_{2.38}\text{H}_{0.62}$ ($V = 65.140 \text{ \AA}^3$).²³

The ND pattern of $\text{Ba}(10)\text{-TiH}_2$ was collected to investigate the presence of the hydride in $\text{BaTiO}_{2.5}\text{H}_{0.5}$ (Fig. S3 and Table S1†). Rietveld refinement was performed by assuming that the secondary phase is a $\text{BaTiO}_{3-x}\text{H}_x$ cubic perovskite with a $Pm\bar{3}m$ structural model, where Ba, Ti, and O/H atoms are placed at the Wyckoff position of $1a$ (0, 0, 0), $1b$ (0.5, 0.5, 0.5), and $3c$ (0, 0.5, 0.5), respectively. Cubic TiH_2 ($Fm\bar{3}m$) was added as a primary phase. Refinement converged to O and H occupancies of $g(\text{O}) = 0.886(2)$ and $g(\text{H}) = 0.114(2)$, which yields the $\text{BaTiO}_{2.658(6)}\text{-H}_{0.342(6)}$ composition and supports the notion that perovskite phase contains hydride. We note here that the difference in the neutron scattering lengths of oxygen and hydrogen (O: 5.803 fm, H: -3.741 fm)³² gives the composition $\text{BaTiO}_{2.438(6)}$ when the refinement is performed by assuming that the secondary phase is oxygen-deficient $\text{BaTiO}_{3-\delta}$. However, because the formation of oxygen-deficient $\text{BaTiO}_{3-\delta}$ is ruled out by considering the lattice volumes estimated by the XRD analysis, the ND results support the formation of an oxyhydride.

The degrees of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ and BaCO_3 formation were determined by Rietveld refinement of the XRD patterns of $\text{Ba}(\alpha)\text{-TiH}_2$. We note here that components (less than about 1%) that are not detected in the XRD analysis are not considered. As shown in Fig. 2, the mass fraction of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ is 0% at $0 \leq \alpha \leq 1$ and higher at $3 \leq \alpha \leq 10$ (1.6% to 8.7%). However, a lower fraction was observed at $\alpha = 15$ (4.5%). The addition of Ba to TiH_2 facilitates the formation of $\text{BaTiO}_{2.5}\text{H}_{0.5}$, while excess Ba inhibits its formation. Thus, the optimum amount of $\text{Ba}(\text{OH})_2$ needed to form $\text{BaTiO}_{2.5}\text{H}_{0.5}$ corresponds to $\alpha = 10$. The mass fraction of the formed BaCO_3 was 0% at $0 \leq \alpha \leq 5$ but higher at $10 \leq \alpha \leq 15$ (0.7 to 4.3%), which implies that unreacted $\text{Ba}(\text{OH})_2$ remains at $\alpha \geq 10$. The samples also exhibited colors that depend on the amounts of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ and BaCO_3 amounts (Fig. S4†). $\text{Ba}(0)\text{-TiH}_2$ and $\text{Ba}(5)\text{-TiH}_2$ are gray, which is typical of TiH_2 , while $\text{Ba}(10)\text{-TiH}_2$ is dark blue, which is typical of $\text{BaTiO}_{2.5}\text{H}_{0.5}$,²³ which also supports the notion that the $\text{BaTiO}_{2.5}\text{H}_{0.5}$ perovskite oxyhydride had formed. $\text{Ba}(15)\text{-TiH}_2$ is brown, which is possibly due to mixed colors associated with TiH_2 , $\text{BaTiO}_{2.5}\text{H}_{0.5}$, and BaCO_3 .

The SEM image of $\text{Ba}(0)\text{-TiH}_2$ revealed that the particle size of TiH_2 ranged from several to tens of μm (Fig. S5 and S6†). Particle size was not affected by the amount of added Ba, which

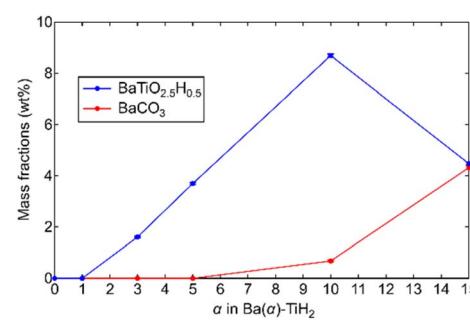

Fig. 2 Mass fractions of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ and BaCO_3 in $\text{Ba}(\alpha)\text{-TiH}_2$ determined by Rietveld refinements of the XRD patterns of $\text{Ba}(\alpha)\text{-TiH}_2$. Cubic TiH_2 ($Fm\bar{3}m$), cubic $\text{BaTiO}_{2.5}\text{H}_{0.5}$ ($Pm\bar{3}m$), and orthorhombic BaCO_3 ($Pnma$) phases were applied during the analysis.

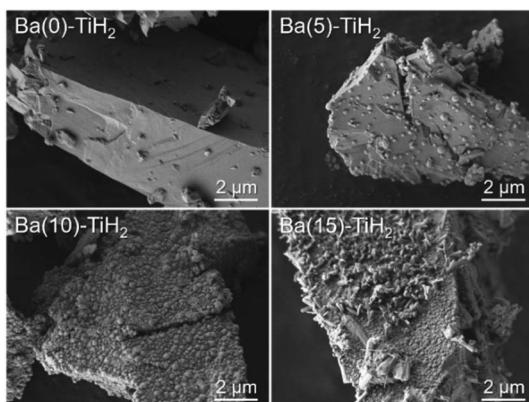

Fig. 3 SEM images of $\text{Ba}(\alpha)\text{-TiH}_2$ ($\alpha = 0, 5, 10$, and 15) at $100\,000$ \times magnification.

agreed with the identical specific surface area of $\text{Ba}(\alpha)\text{-TiH}_2$ ($0 \leq \alpha \leq 15$; $1.65\text{--}1.91\,\text{m}^2\,\text{g}^{-1}$). The particle surface of $\text{Ba}(0)\text{-TiH}_2$ and $\text{Ba}(1)\text{-TiH}_2$ were relatively smooth; by comparison, nanoparticles of *ca.* $100\text{--}200\,\text{nm}$ were dispersed on the TiH_2 surface of $\text{Ba}(3)\text{-TiH}_2$ and $\text{Ba}(5)\text{-TiH}_2$ (Fig. 3). The nanoparticles were expected to be $\text{BaTiO}_{2.5}\text{H}_{0.5}$ because $\text{BaTiO}_{2.5}\text{H}_{0.5}$ in addition to TiH_2 was observed in the XRD patterns of $\text{Ba}(3)\text{-TiH}_2$ and $\text{Ba}(5)\text{-TiH}_2$ (Fig. 1). The EDX mappings in the HAADF-STEM image of $\text{Ru/Ba}(5)\text{-TiH}_2$ show that Ba and O elements were localized at the nanoparticles (Fig. 4), thus supporting the identification of the nanoparticles as $\text{BaTiO}_{2.5}\text{H}_{0.5}$. The Ba/Ti atomic ratio estimated from the XPS analysis was higher than that of the feed ratio in the preparation, also supporting that the nanoparticles are $\text{BaTiO}_{2.5}\text{H}_{0.5}$. The SEM image of $\text{Ba}(10)\text{-TiH}_2$ showed that the $\text{BaTiO}_{2.5}\text{H}_{0.5}$ nanoparticles fully covered the TiH_2 particle. Moreover, the SEM image of $\text{Ba}(15)\text{-TiH}_2$ showed needle-shaped particles on the $\text{BaTiO}_{2.5}\text{H}_{0.5}$ nanoparticles. The crystals were identified as BaCO_3 according to the XRD pattern because BaCO_3 generally formed needle-shape crystals.³³ Therefore, $\text{BaTiO}_{2.5}\text{H}_{0.5}$ was formed as $100\text{--}200\,\text{nm}$ nanoparticles at $\alpha \geq 3$, and BaCO_3 was formed as needle shape particles at $\alpha \geq 10$ (Fig. 5).

The XRD patterns of $\text{Ba}(\alpha)\text{-TiO}_2$ ($\alpha = 0, 5, 10, 15$) synthesized as comparison are shown in Fig. S8.[†] All samples showed

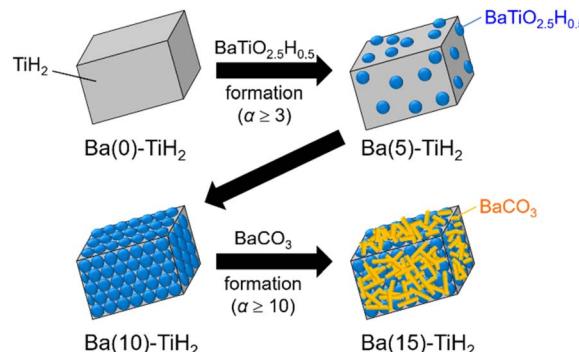

Fig. 5 Images of the morphological change of $\text{Ba}(\alpha)\text{-TiH}_2$.

predominantly rutile TiO_2 . $\text{Ba}(0)\text{-TiO}_2$ was the single phase of TiO_2 , whereas $\text{Ba}(\alpha)\text{-TiO}_2$ ($\alpha = 5, 10$, and 15) contained additional Ba_2TiO_4 and BaCO_3 . The cubic phase of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ formed in $\text{Ba}(\alpha)\text{-TiH}_2$ was not observed with the addition of any amount of $\text{Ba}(\text{OH})_2$. Therefore, TiH_2 is essential for $\text{BaTiO}_{2.5}\text{H}_{0.5}$ formation.

How is TiH_2 involved in the formation of $\text{BaTiO}_{2.5}\text{H}_{0.5}$? TiH_2 consumed to form $\text{BaTiO}_{2.5}\text{H}_{0.5}$ is calculated to be 2.1% for $\text{Ba}(10)\text{-TiH}_2$ which contains the highest amount of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ (8.7%; Fig. 2), suggesting that only the surface part of the TiH_2 particles contributes to the formation. This is supported by the SEM and TEM observations (Fig. 3 and 4). Because metal hydrides are generally unstable in an oxidizing atmosphere, the surface of TiH_2 particles is known to be covered by an oxide film of TiO_2 .³⁴ TiH_2 (Ti^{2+}) partially oxidized to TiO_2 (Ti^{4+}) possibly contributes to the formation of $\text{BaTiO}_{2.5}\text{H}_{0.5}$ ($\text{Ti}^{3.5+}$) via the reaction $\text{Ba}(\text{OH})_2 + 0.5x\text{TiH}_2 + (1 - 0.5x)\text{TiO}_2 \rightarrow \text{BaTiO}_{3-x}\text{H}_x + \text{H}_2\text{O}$. Moreover, the effect of Ba reagents on $\text{BaTiO}_{2.5}\text{H}_{0.5}$ formation was investigated. The XRD patterns of $\text{Ba}(10)\text{-TiH}_2$ synthesized using $\text{Ba}(\text{CH}_3\text{COO})_2$ or $\text{Ba}(\text{NO}_3)_2$ instead of $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ are shown in Fig. S9.[†] The XRD pattern of $\text{Ba}(10)\text{-TiH}_2$ synthesized via $\text{Ba}(\text{CH}_3\text{COO})_2$ showed only TiH_2 and $\text{Ba}(\text{CH}_3\text{COO})_2$ and no formation of $\text{BaTiO}_{2.5}\text{H}_{0.5}$. While $\text{Ba}(10)\text{-TiH}_2$ synthesized via $\text{Ba}(\text{NO}_3)_2$ contained $\text{BaTiO}_{2.5}\text{H}_{0.5}$, its mass fraction (1.5%) was only 0.17-times that of the $\text{Ba}(10)\text{-TiH}_2$ synthesized via $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ (8.7%). These observations suggest that the hydroxide ion (OH^-) promotes the formation of $\text{BaTiO}_{2.5}\text{H}_{0.5}$.

The ammonia synthesis activities of $\text{Ru/Ba}(\alpha)\text{-TiH}_2$ ($0 \leq \alpha \leq 15$) catalysts were examined at $300\text{--}400\,\text{°C}$ under ambient pressure (Fig. 6a). Ammonia synthesis rates of all catalysts increased at elevated temperature. $\text{Ru/Ba}(0)\text{-TiH}_2$ exhibited ammonia synthesis activity at $\geq 375\,\text{°C}$. The ammonia synthesis rate of $\text{Ru/Ba}(0)\text{-TiH}_2$ ($0.05\,\text{mmol g}^{-1}\text{ h}^{-1}$ at $400\,\text{°C}$) was 0.04 times that of Ru/Cs-MgO ($1.24\,\text{mmol g}^{-1}\text{ h}^{-1}$ at $400\,\text{°C}$), which was often called as benchmark Ru catalysts.^{35,36} The activity of $\text{Ru/Ba}(1)\text{-TiH}_2$ ($0.20\,\text{mmol g}^{-1}\text{ h}^{-1}$ at $400\,\text{°C}$) was higher than that of $\text{Ru/Ba}(0)\text{-TiH}_2$ but remained lower than that of Ru/Cs-MgO . However, by contrast, the activities of $\text{Ru/Ba}(3)\text{-TiH}_2$, $\text{Ru/Ba}(5)\text{-TiH}_2$, and $\text{Ru/Ba}(10)\text{-TiH}_2$ ($1.73, 2.08$, and $3.05\,\text{mmol g}^{-1}\text{ h}^{-1}$ at $400\,\text{°C}$, respectively) were higher than that of Ru/Cs-MgO by a factor of 1.40, 1.68, and 2.46, respectively. Activity increased

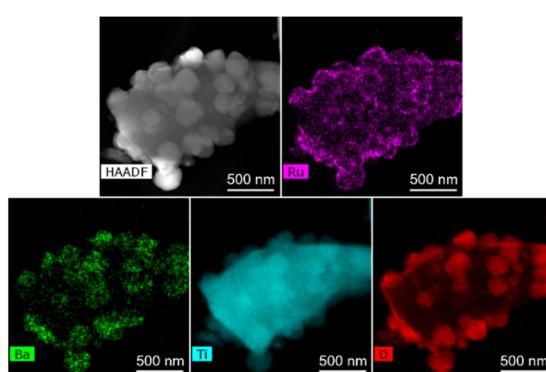

Fig. 4 STEM-HAADF and EDX mapping images of $\text{Ru/Ba}(5)\text{-TiH}_2$.

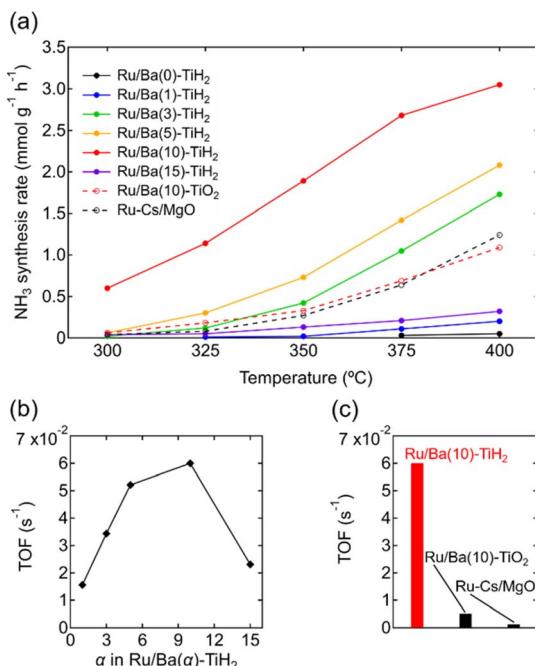

Fig. 6 (a) Temperature dependence of the NH₃ synthesis rates for Ru/Ba(α)-TiH₂ ($\alpha = 0, 1, 3, 5, 10$, and 15), Ru/Ba(10)-TiO₂, and Ru-Cs/MgO (reaction conditions: catalyst, 0.2 g; reaction gas, H₂/N₂ = 3 at a flow rate of 80 mL min⁻¹; pressure = ambient pressure). (b) TOF of Ru/Ba(α)-TiH₂ ($\alpha = 0, 1, 3, 5, 10$, and 15) at 350 °C as functions of Ba(OH)₂ added amount α . (c) TOF of Ru/Ba(10)-TiH₂, Ru/Ba(10)-TiO₂, and Ru-Cs/MgO at 350 °C.

with the increase in Ba addition amount in $0 \leq \alpha \leq 10$, whereas the activity decreased at $\alpha = 15$ ($0.32 \text{ mmol g}^{-1} \text{ h}^{-1}$ at 400 °C). Therefore, the most active catalyst among Ru/Ba(α)-TiH₂ ($0 \leq \alpha \leq 15$) was Ru/Ba(10)-TiH₂. The activity of Ru/Ba(10)-TiH₂ was higher than that of Ru/Ba(10)-TiO₂ ($1.09 \text{ mmol g}^{-1} \text{ h}^{-1}$ at 400 °C), thereby suggesting that BaTiO_{2.5}H_{0.5} formation was responsible for the high activity of Ru/Ba(10)-TiH₂.

The TOF for the ammonia synthesis reaction at 350 °C was estimated to obtain a deeper insight into the correlation between ammonia synthesis activity and catalyst composition. As shown in Fig. 6b, the TOF of Ru/Ba(α)-TiH₂ increased with increasing amount of Ba addition at $1 \leq \alpha \leq 10$ ($1.56 \times 10^{-2} \text{ s}^{-1}$ to $6.00 \times 10^{-2} \text{ s}^{-1}$) but decreased at $\alpha = 15$ ($2.31 \times 10^{-2} \text{ s}^{-1}$). This trend was consistent with the trend of the mass fraction of BaTiO_{2.5}H_{0.5} (Fig. 2); these observations support that BaTiO_{2.5}H_{0.5} formation contributes to the increase in ammonia synthesis activity. This was supported by the fact that the TOF of Ru/Ba(10)-TiH₂ ($6.00 \times 10^{-2} \text{ s}^{-1}$) was 12 and 46 times larger than those of Ru/Ba(10)-TiO₂ ($0.51 \times 10^{-2} \text{ s}^{-1}$) and Ru-Cs/MgO ($0.13 \times 10^{-2} \text{ s}^{-1}$), respectively (Fig. 6c). Interestingly, the TOF of Ru/Ba(15)-TiH₂ ($2.31 \times 10^{-2} \text{ s}^{-1}$) was lower than that of Ru/Ba(5)-TiH₂ ($5.21 \times 10^{-2} \text{ s}^{-1}$) despite the higher mass fraction of BaTiO_{2.5}H_{0.5} for Ru/Ba(15)-TiH₂ (4.48%) than that for Ru/Ba(5)-TiH₂ (3.70%). The formation of BaCO₃, which partially covered the BaTiO_{2.5}H_{0.5} particles (Fig. 3), was expected to inhibit the ammonia synthesis reaction of Ru/Ba(15)-TiH₂ because BaCO₃ was stable in the reaction temperature.³⁷

Table 2 Reaction orders^a for ammonia synthesis reaction over Ru/Ba(10)-TiH₂ and Ru-Cs/MgO

Catalyst	Order		
	H ₂	N ₂	NH ₃
Ru/Ba(10)-TiH ₂	0.15	0.79	-0.36
Ru-Cs/MgO	-0.59	0.89	0.11

^a Estimated from results of kinetic analysis shown in Fig. S8.

Finally, reaction orders with respect to H₂, N₂ and NH₃ were investigated using the method of Aika *et al.*²⁷ (Fig. S10 and Table S3†). The H₂ order of Ru/Ba(10)-TiH₂ (0.15) was higher than that of Ru-Cs/MgO (-0.59), reflecting that compared to Ru-Cs/MgO, Ru/Ba(10)-TiH₂ had less hydrogen poisoning, which prevented N₂ dissociation on Ru (Table 2).¹⁶ The low hydrogen poisoning effect allowed Ru/Ba(10)-TiH₂ to exhibit higher ammonia synthesis activity than Ru-Cs/MgO. The N₂ orders of Ru/Ba(10)-TiH₂ (0.79) and Ru-Cs/MgO (0.89) were virtually coincident, reflecting that the rate-determining step for both catalysts was the unimolecular cleavage reaction of N₂ for both catalysts. Moreover, the orders of Ru/Ba(10)-TiH₂ (H₂ order: 0.15, N₂ order: 0.79) agreed well with the reported orders of Ru/BaTiO_{2.5}H_{0.5} (H₂ order: 0.2, N₂ order: 0.7).¹⁷ Because Ru/BaTiO₃, the reference catalyst for Ru/BaTiO_{2.5}H_{0.5}, exhibits stronger hydrogen poisoning due to the absence of hydride in the support perovskite (H₂ order: -0.89, N₂ order: 1.2),¹⁷ the agreement of the H₂ and N₂ orders between Ru/Ba(10)-TiH₂ and Ru/BaTiO_{2.5}H_{0.5} supports the formation of BaTiO_{2.5}H_{0.5} in Ru/Ba(10)-TiH₂. The NH₃ order of Ru/Ba(10)-TiH₂ (-0.36) was higher than that reported for Ru/BaTiO_{2.5}H_{0.5} (-0.64), indicating that the ammonia decomposition reaction on Ru/Ba(10)-TiH₂ was relatively inhibited. The inhibition may be attributed to the reaction pressure of this study (ambient pressure) being lower than that of reported Ru/BaTiO_{2.5}H_{0.5} (5 MPa) because the ammonia decomposition reaction generally proceeded at a higher pressure.³⁸

Conclusions

The selection of appropriate raw materials allowed for BaTiO_{2.5}H_{0.5} perovskite oxyhydride nanoparticles to be formed on the TiH₂ surface through the conventional wet impregnation method. BaTiO_{2.5}H_{0.5} crystallized as *ca.* 100–200 nm sized nanoparticles on the surface of TiH₂. Hydroxide in Ba(OH)₂ involved BaTiO_{2.5}H_{0.5} formation. Ru-loaded catalysts inhibited hydrogen poisoning and showed higher ammonia synthesis activity compared to that of the Ru-Cs/MgO benchmark catalyst. We believe that further investigation of oxyhydride prepared *via* the wet impregnation method accelerates the use of oxyhydride as ammonia synthesis catalysts.
