# The synthesis and super capacitive characterization of microwave-assisted highly crystalline $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> nanoheterostructures†

Rajendra Panmand, Da Yogesh Sethi, Animesh Jha Db and Bharat Kale + \*a

A facile microwave-assisted solvothermal process for the synthesis of narrow-size distributed  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>,  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub>, and Fe<sub>3</sub>O<sub>4</sub> nanostructures was demonstrated using PVP as a surfactant. During the reaction, the influence of the reaction media, such as the mixture of ethylene glycol and water on the formation of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>,  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub>, and Fe<sub>3</sub>O<sub>4</sub> was systematically studied. Interestingly, pure aqueous medicated solvothermal reaction conferred phase pure rhombohedral Fe<sub>2</sub>O<sub>3</sub> (hematite) and linearly upsurging the formation of cubic Fe<sub>3</sub>O<sub>4</sub> (magnetite) with the increasing concentration of EG and further, in pure EG, it deliberated cubic  $Fe_3O_4$ . FESEM and FETEM images of  $\alpha$ - $Fe_2O_3/Fe_3O_4$  nano heterostructure clearly showed the nanosized Fe<sub>3</sub>O<sub>4</sub> particles of 4-6 nm decorated onto Fe<sub>2</sub>O<sub>3</sub> nanoparticles. Further, the electrochemical properties of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>,  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub>, and Fe<sub>3</sub>O<sub>4</sub> nanoparticles were investigated with galvanostatic charge-discharge and cyclic voltammetry measurements using a 3-electrode system. The findings show that their specific capacitances are linked to the type of iron oxide. More significantly, the  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> nanoheterostructure exhibited the utmost capacitance of 165 F g<sup>-1</sup>, which is greater than that of pristine  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> and Fe<sub>3</sub>O<sub>4</sub>. Enhancement in the electrochemical performance was found due to the improved charge transfer that occurred at the interface of the nanoheterostructure. The nanoparticles of Fe<sub>3</sub>O<sub>4</sub> deposited on the Fe<sub>2</sub>O<sub>3</sub> increased the active sites, which accelerated the process of adsorption and desorption of ions, thereby enhancing the interface-assisted charge transfer and reducing the internal resistance, which is ultimately responsible for enhanced capacitance. Such heterostructures of nano iron oxide may fulfill the requirements of electrodes in supercapacitors.

## Introduction

The engineering of supercapacitors for electrical charge storage is an emerging technology where the materials used must demonstrate higher power (*P*) and energy density, muchenhanced reversibility, and longer cycle life when compared with batteries and common capacitors. <sup>1-4</sup> The electrochemical capacitor was categorized as electric double-layer capacitors (ELDCs) or Faraday pseudocapacitors depending on the energy storage mechanism. <sup>5-8</sup> As compared to EDLCs, faradaic pseudocapacitors exhibit greater energy density (*E*) and specific capacitance owing to their reversible multi-electron redox/faradaic reactions. <sup>9</sup>

In general, transition metal oxides (TMOs) are used as electrode materials for pseudocapacitors. TMOs are promising materials as electrodes in pseudo or redox supercapacitors

because of the increased E as a result of redox reactions. Amongst the TMOs, ruthenium dioxide (RuO<sub>2</sub>) is recognized as the most promising electrode material owing to its good electrical conductivity and multiple redox states. 10 However, owing to its high cost and toxicity, RuO2 is limited in its practical applications, thus other metal oxides that are inexpensive and environmentally friendly have gained significance in the areas of supercapacitors. In this respect, transition metal oxides, such as  $MnO_2$ , 11 NiO, 12  $Co_2O_3$ , 13  $Cu_xO$ , 14  $V_2O_5$ , 15  $SnO_2$ , 16a and a few binary metal oxides, such as NiMoO<sub>4</sub>, 16b,c have been identified as potential alternatives to RuO2. Recently, hematite (Fe2O3) and magnetite (Fe3O4) have emerged as promising oxide materials for supercapacitors, as both oxide forms are abundant in nature and non-toxic.17a,b Iron oxides (Fe3O4 and Fe2O3) are predicted for use as electrode materials with negative potential windows, large theoretical capacitance, and unique reversible redox reactions (Fe<sup>2+</sup>/Fe<sup>3+</sup>). 18 However, the 'P', supercapacitance and corresponding small 'E' of the Fe2O3 electrode are still quite low due to its very low electrical conductivity (~10<sup>-14</sup> S cm<sup>-1</sup>).19 Significant research has been carried out to overcome the limitations. Notably, a number of approaches, such as the synthesis of doped Fe<sub>2</sub>O<sub>3</sub> electrodes, nanostructured Fe<sub>2</sub>O<sub>3</sub> electrodes, core-shell nanorod arrays, oxygen vacancy-induced

**RSC Advances** 

Fe<sub>2</sub>O<sub>3</sub> electrodes, and Fe<sub>2</sub>O<sub>3</sub> composite electrodes have been investigated.<sup>20-23</sup> Amongst these approaches, the fabrication of Fe<sub>2</sub>O<sub>3</sub> composite electrodes with graphene,<sup>24</sup> mesoporous carbon,25 PANI,26 and SnO2 (ref. 27) was also investigated. Although the enhanced super capacitive performance was attained, the limited electronic and ion transport remains a critical concern for Fe<sub>2</sub>O<sub>3</sub> composites to be high-performance electrodes. Very few reports are available on the synthesis of the composite of Fe<sub>2</sub>O<sub>3</sub> and highly conductive Fe<sub>3</sub>O<sub>4</sub> for energy storage applications. Tang et al. reported enhanced electrochemical performance due to the improvement in the charge transport of Fe<sub>3</sub>O<sub>4</sub>/Fe<sub>2</sub>O<sub>3</sub> composites.<sup>21</sup>

Synthesis of Fe<sub>3</sub>O<sub>4</sub> nanoparticles using monovalent precursor is quite difficult and hence many reports on Fe<sub>3</sub>O<sub>4</sub> preparation involve mixing Fe<sup>2+</sup> and Fe<sup>3+</sup> in different ratios.<sup>28</sup> Herein, we have synthesized the nanostructured Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>3</sub>O<sub>4</sub>/ Fe<sub>2</sub>O<sub>3</sub> nanoscale heterostructure, and Fe<sub>3</sub>O<sub>4</sub> using monovalent precursor (FeCl<sub>3</sub>· $6H_2O$ ) using the facile microwave method. The formation of nanoscale heterostructure was demonstrated by a microwave solvothermal method using water ethylene glycol mixture as a reaction medium. The details of the electrochemical characterization of the nanoscale heterostructure materials are also discussed alongside the capacitance measurements. The influence of nano-scale phase combination on capacitance is compared and discussed in terms of charge storage.

## **Experimental**

All chemicals used here, namely ferric chloride (FeCl<sub>3</sub>, >99.9%), sodium hydroxide (NaOH, >99.0%), ethylene glycol (EG, >99.0%), were procured from SD Fine Chemicals Ltd, Mumbai, India and no further purification step was adopted for the synthesis of nanoparticles of iron oxides.

For the synthesis of nanoparticles of iron oxide, 0.35 g (50 mM) FeCl<sub>3</sub>·6H<sub>2</sub>O, 0.3 g (150 mM) NaOH were mixed with 20 mL of ethylene glycol and water in a 100 mL beaker, as shown in Table 1. The homogenous solution was sealed in a doublewalled digestion vessel lined with Teflon. A Milestone's Start D microwave digestion system oven equipped with a solution digester stage was used for heating the solutions containing FeCl<sub>3</sub>/NaOH with EG for 25 min to a controlled temperature of 150 °C. After the microwave digestion, each solution, listed in Table 1, was cooled to room temp. After centrifugal separation, the product was taken and washed in deionized water and 100% ethanol. For four hours, the reaction product was dried at 80 °C in a vacuum.

Table 1 Water to ethylene glycol ratio used in reactions

Sample ID	Solvent	Volume ratio		
F1	Water	_		
F2	Water: EG	3:1		
F3	Water : EG	2:2		
F4	Water: EG	1:3		
F5	EG	_		

The phase purity, structural, and morphological and microstructural analyses of the synthesized iron oxide phase mixtures including heterostructure were examined using an Xray Powder Diffractometer XRD (Bruker (D8)), HR 800-Raman Spectroscopy (Horiba Joblin Yvon, France), and FESEM (FEI NOVANANOSEM 450), respectively.

#### **Electrochemical measurements**

Carbon paper was used for making electrodes for electrochemical testing. For each measurement, two carbon paper electrodes with similar surface areas were utilized. The Fe2O3/ Fe<sub>3</sub>O<sub>4</sub> nanoparticles were loaded onto the carbon paper as a substrate, as shown below. Thus, 80 wt% Fe2O3/Fe3O4 was added to 10 wt% polyvinylidene fluoride (PVDF) and acetylene black each. The viscous slurry was prepared by adding 5-7 mL of NMP (N-methyl-2-pyrrolidone) into the above mixture. The carbon paper substrate was then covered with this slurry. The electrodes were dried for 6-7 hours at 100 °C. In an aqueous 6 M KOH solution, electrochemical cyclic voltammetry experiments were performed from the -1 to 0.2 V range of potential at varied scan rates.

#### Electrochemical impedance spectroscopy study

Electrochemical impedance (EI) spectroscopy measurements were executed for a symmetrical supercapacitor cell made up of Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> nanoparticles in an aqueous 1 M Na<sub>2</sub>SO<sub>4</sub> electrolyte. The study was performed using a frequency of 10 kHz to 10 MHz range and AC amplitude of 10 mV without the use of an external DC applied voltage.

#### Results and discussion

The XRD patterns of the self-assembled bipyramidal-like α-Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> nanoparticles are shown in Fig. 1a and b, prepared using different water-to-EG ratios as solvents. The XRD pattern of the pure aqueous mediated (F1) sample showed the presence of rhombohedral hematite without any impurity peaks (JCPDS no. 072-0469). Based on the powder diffraction data presented in Fig. 1a, the lattice constants were calculated for each sample, and it was determined that the values of lattice constants are a = b = 5.030 Å, c = 13.87 Å, which are comparable to the JCPDS

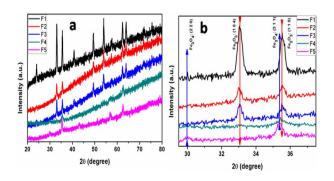

Fig. 1 Full XRD patterns (a) and magnified XRD pattern (b) of the  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> prepared using different water to EG ratios as a solvent.

data for hematite powder (a = b = 5.034 Å and c = 13.57 Å). As the amount of the EG in the solvent increased to 50% (F3) and 75% (F4), the additional peaks of cubic magnetite (JCPDS-072-0748) (Fe<sub>3</sub>O<sub>4</sub>) and (Fe<sub>2</sub>O<sub>3</sub>-JCPDS no. 072-0469) appeared. The sample prepared using pure EG solvent (F5) showed the formation of cubic magnetite (JCPDS-074-0748). The magnified pattern (29.5 to 37.5°) is shown in Fig. 1b for clarity. From Fig. 1b, it is revealed that the XRD peak intensity of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> (1.1 0) and (1 0 4) diminished with an increase in EG and other planes corresponding to Fe<sub>3</sub>O<sub>4</sub> (2 2 0) and (3 1 1) appeared, distinctly. The Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>3</sub>O<sub>4</sub>@Fe<sub>2</sub>O<sub>3</sub> heterostructure and Fe<sub>3</sub>O<sub>4</sub> can be easily prepared using Fe(III)Cl<sub>3</sub> and by varying the water to EG solvent ratio during the reaction.

The morphological evolution of the α-Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> prepared at different water: EG ratios was conducted using FESEM. Fig. 2 shows the FESEM images at different magnifications of samples obtained with different EG: water ratios (F1, F3, and F5). Uniformity and homogeneity of particles can be revealed from low magnification FESEM images. However, high-magnification images are valuable for studying the effect of the solvent ratio on morphology. Fig. 1a and b show the FESEM images of sample F1 (made purely in water medium), which revealed the uniform and monodisperse self-assembled bipyramidal α-Fe<sub>2</sub>O<sub>3</sub> nanoparticles of size 140-150 nm in length and 100-120 nm in diameter (see Fig. 1b). The bipyramidal α-Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> nanoheterostructure nanoparticles with sizes 80-90 nm in length and 50-70 nm in diameter were observed for samples prepared using 1:1 EG to water ratio (F3 see Fig. 1d). However, when the

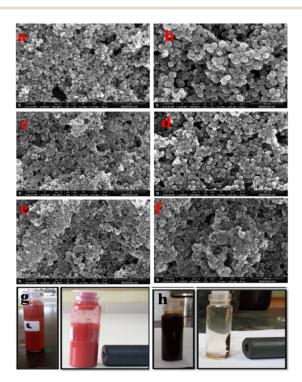

Fig. 2 Images of FESEM at low and high magnification of samples prepared at different EG: water solvent ratios. (a and b): F1, (c and d): F3 and (e and f): F5. Photographs of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> NPs (g) and Fe<sub>3</sub>O<sub>4</sub> NPs (h) before and after magnetic separation with an external magnetic field.

sample was prepared using pure EG as the solvent (F5), monodispersed and spherical Fe<sub>3</sub>O<sub>4</sub> nanoparticles of diameter 30-50 nm were formed without any other phase. From FESEM, it can be concluded that the nanoparticle size of the material declined with increasing EG concentration in the reaction medium. It is obvious because of the low dielectric constant of EG (37) compared to that of water (80), the ionic mobility slowed down, which ultimately controlled the formation and growth of the nanoparticle. Hence, the lower particle size obtained in pure EG is quite justifiable. Fig. 1g and h demonstrate the images of the samples F1 and F5 dispersed in water with and without an external magnetic field. From the image, it is clear that Fe<sub>3</sub>O<sub>4</sub> nanoparticles (sample F5) are well dispersed in water before magnetic separation. However, all Fe<sub>3</sub>O<sub>4</sub> NPs are attracted toward the magnet, after magnetic field application. For comparison, the α-Fe<sub>2</sub>O<sub>3</sub> nanoparticles were also dispersed in water, however, there was no change before and after magnetic separation.

Being a magnetic sample, the sample was dispersed in PVA, and the film was employed for FETEM. Fig. 3 shows the TEM images of the Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> nano-heterostructure prepared using a 1:3 water-to-EG solvent ratio. From TEM images, it is concluded that the tiny Fe<sub>3</sub>O<sub>4</sub> nanoparticles of size 4-6 nm were grown on the Fe<sub>2</sub>O<sub>3</sub> nanoparticles (see Fig. SI 1 in ESI†). TEM images clearly show that the entire Fe<sub>2</sub>O<sub>3</sub> nanoparticles are covered with tiny Fe<sub>3</sub>O<sub>4</sub>. Fig. SF 2 from ESI† shows lattice-resolved HRTEM of Fe<sub>2</sub>O<sub>3</sub>on-Fe<sub>2</sub>O<sub>3</sub> nanoparticles. The interplanar spacing was measured to be about 0.367 nm, which is in good agreement with that of the (012) crystal plane. The SEAD pattern is poor due to the polymer film, which is given in the ESI.†

Raman spectra of iron oxide samples prepared using pure water (F1), water: EG in a 1:1 ratio (F3), and pure EG as the solvent (F5) are shown in Fig. 4. "The Raman spectra of the above-made F1 sample (α-Fe<sub>2</sub>O<sub>3</sub> nanoparticles) do not contain the peaks belonging to  $Fe_3O_4$ . The peaks at 221 and 497 cm<sup>-1</sup> are classified as  $A_{1g}$  modes, whereas the peaks at 244, 292, 406, and 611 cm<sup>-1</sup> are classified as Eg modes".<sup>29,30</sup> From Raman spectra, the peaks in the spectrum of sample F5 (Fe<sub>3</sub>O<sub>4</sub>) at "305 and 534 cm<sup>-1</sup> are reliably allocated to the  $T_{2g}$  mode, whereas the peak at 513 cm<sup>-1</sup> is allocated to the Eg mode and the peak at  $660 \text{ cm}^{-1}$  is allocated to the  $A_{1g}$  mode". However, in sample F3, both iron oxide phase peaks were found, which confirmed the existence of nano-heterostructure.

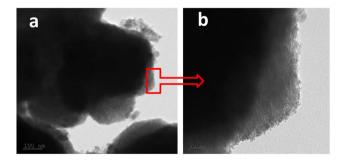

Fig. 3 TEM image of Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> nanocomposite prepared at 1:3 water to EG solvent ratio.

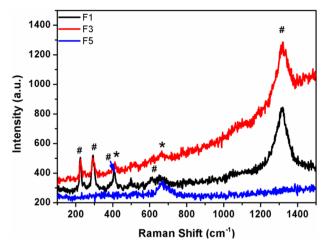

Fig. 4 Raman spectra of samples prepared at different EG: water solvent ratios.

#### **Growth mechanism**

Generally, the growth mechanism consists of two stages, i.e. nucleation of amorphous primary particles followed by slow crystallization and aggregation of primary particles.31,32 In the present case, the diluted Fe<sup>3+</sup> ion aqueous solution was directly digested under microwave hydrothermal conditions at 150 °C. The formation of α-Fe<sub>2</sub>O<sub>3</sub> involved two stapes.<sup>33,34α</sup> Initially, It may be that β-FeOOH is formed by hydrolysis of ( $[Fe(H_2O)_6]^{3+}$ ) in an aqueous solution and further, the β-FeOOH undergoes a transformation to α-Fe<sub>2</sub>O<sub>3</sub> via the dissolution/re-precipitation mechanism.34b EG is acting as a reducing agent apart from the solvent medium. Initially, it combined with FeCl<sub>3</sub> to form iron alkoxide nuclei, which then further grew at hydrothermal conditions and formed Fe<sub>3</sub>O<sub>4</sub> nanoparticles of size 30-50 nm in size. However, in a mixture of EG and water solvent, the α-Fe<sub>2</sub>-O<sub>3</sub>@Fe<sub>3</sub>O<sub>4</sub> heterostructure was formed. The possible formation and growth mechanism are shown in Fig. 5. In aqueous EG, iron alkoxide formation along with FeOOH is quite understood. Preferentially, the formation of Fe<sub>2</sub>O<sub>3</sub> from FeOOH takes place

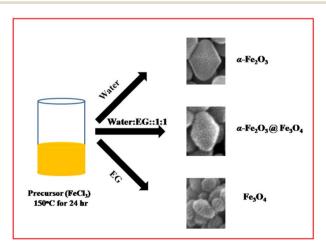

Fig. 5 The schematic representation of the growth mechanism.

first, and then alkoxide gets reduced to  $Fe_3O_4$ . Hence, we can see the deposition of  $Fe_3O_4$  nanoparticles on the  $Fe_2O_3$  particle (Fig. 5). During the reaction, the average dielectric constant was decreased due to EG in the water, which ultimately controlled the growth of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>@Fe<sub>3</sub>O<sub>4</sub> resulting in a lower nanoparticle size of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O.

#### **Electrochemical study**

Cyclic voltammetry (CV) is used to characterize the supercapacitive behavior of any material. The  $C_{\rm sp}$  of the cell was evaluated from the CV curve as per the following equation:

$$C_{\rm sp} = \frac{I}{\frac{\mathrm{d}v}{\mathrm{d}t}m} \tag{1}$$

Here,  $C_{\rm sp}$  indicates the specific capacitance of a single electrode (in F  $g^{-1}$ ), I indicate the discharge current (in A); m indicates the active materials mass (in g); dv/dt indicates the slope of the discharge curve. Fig. 6a-c illustrates the CV curves obtained for samples F-1, F-3, and F-5 electrodes using a 3-electrode cell system. The voltage scan rate was 5 to 100 mV s<sup>-1</sup> in 6 M KOH electrolyte with the Pt plate as the counter electrode and an SCE ("saturated calomel electrode") as the reference electrode having a potential of -1.0-0.2 V range. Each sample's CV curve is approximately symmetrical, with small redox peaks. The cathodic peaks shift "negatively" while the anodic peaks shift "positively" with the increase in scan rates. The samples exhibit pseudocapacitive characteristics. When scan rates increased from 5 to 100 mV s<sup>-1</sup>, the peak I increased with a negligible change in the CV shape, indicating its good electrochemical reversibility and high-power features. The CV curves have an obvious pair of redox peaks at -0.54 and -0.86 V. The presence of obvious redox peaks indicates good electrochemical performance attributed to the change in the Fe valence state, i.e., F(II) $\leftrightarrow$  Fe(III). 35a

The galvanostatic charge-discharge curves and performance rate of the F-1, F-3, and F-5 samples with current densities ranging from 0.5 to 4 A  $\rm g^{-1}$  are displayed in Fig. 6d-f. The modest charge-discharge platforms that are formed in samples F-1, F-3, and F-5, as shown in Fig. 6d-f, suggesting that tiny

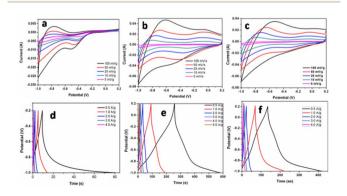

Fig. 6 Cyclic voltammeter (potential (V) vs. saturated calomel electrode) and galvanostatic charge—discharge curve of F1 (a and d), F3 (b and e), and F5 (c and f).

Paper RSC Advances

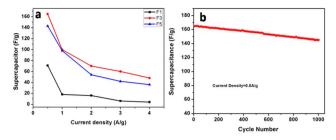

Fig. 7 (a) Specific capacitance calculated for F1, F3, and F5 based on the charge/discharge curves as a function of current densities. (b) Cycling stability of the F3 electrode collected at a current density of 0.5 A  $\rm q^{-1}$  for 1000 cycles.

redox processes take place during the charge-discharge process. It is consistent with the modest redox peaks seen in the CV profile. In all three samples, there are 2 variance ranges that are present during the charge and discharge processes. The potential time dependence is linear and nonlinear below -0.4 Vand above -0.4 V resp. in which the linear shows pure doublelayer capacitance behaviour resulting from charge separation at the electrode-electrolyte interface<sup>35b</sup> while the nonlinear is due to the typical pseudo-capacitance behaviour. High specific capacitance values are produced at small current densities by completely accumulating charges in the electrode's inner active sites. The specific capacitances of F-1, F-2, and F-3 are 49, 165 and 157 F g<sup>-1</sup> at 0.5 A g<sup>-1</sup>, respectively. Due to the movement of electric charges being out of phase with current rates, the specific capacitance value declines as current density increases. At very fast charge-discharge, only the outer active surface of the electrode material is used for charge storage.<sup>36</sup> The specific capacitance change with current density is summarized in Fig. 7a and Table 2. As shown in Fig. 7a, the charge/discharge curves of the 3 electrodes collected at a 0.5 A g<sup>-1</sup> current density showed that the sample F3 (Fe<sub>3</sub>O<sub>4</sub>@Fe<sub>2</sub>O<sub>3</sub>) electrode presented the most prolonged charge/discharge curves, confirming its outstanding capacitive performance than F1 (Fe<sub>2</sub>O<sub>3</sub>) and F5 (Fe<sub>3</sub>O<sub>4</sub>). Additionally, the internal resistance (IR) drop of 0.17 V for the F3 electrode was much smaller than 0.21 V for the F5 electrode, indicating the enhanced electrical conductivity of the F3 (Fe<sub>3</sub>O<sub>4</sub>@Fe<sub>2</sub>O<sub>3</sub>) electrode.

Fig. SI  $3\dagger$  shows the  $N_2$  adsorption–desorption isotherms of the as-prepared F1, F2 and F3 heterostructures. The Brunauer–Emmett–Teller (BET) specific surface areas of F1, F2, and F3

heterostructures were measured to be 19.9, 34.5, and 32.14 m<sup>2</sup> g<sup>-1</sup>, respectively. Results showed that the surface area of Fe<sub>3</sub>-O<sub>4</sub>@Fe<sub>2</sub>O<sub>3</sub> is higher than Fe<sub>3</sub>O<sub>4</sub> and Fe<sub>2</sub>O<sub>3</sub>. Also, it has been reported that the junction formation at the Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> interface can significantly improve the charge transport of Fe<sub>3</sub>O<sub>4</sub>@-Fe<sub>2</sub>O<sub>3</sub> composites.<sup>37</sup> Hence, Due to high surface area and improved charge transport, the Fe<sub>3</sub>O<sub>4</sub>@Fe<sub>2</sub>O<sub>3</sub> shows improved capacitance than Fe<sub>3</sub>O<sub>4</sub> and Fe<sub>2</sub>O<sub>3</sub>.

The cycling stability of the electrode materials used in supercapacitor applications is an additional essential parameter. "Constant current charge–discharge cycling" at a 0.5 A g<sup>-1</sup> current density was recorded in order to assess the cycling stability of F3 electrodes (Fig. 7b). The calculated specific capacitance values were plotted as a function of cycle numbers (in Fig. 7b). A slight reduction of around 12% of the initial capacitance was found for the F3 electrode after 1000 cycles. The comparison of the present supercapacitor with the reported supercapacitor is shown in Table SI 1.† The table shows that our supercapacitor is superior to the reported values.

For energy storage devices, it is very important to know the value of 'E' and 'P'. The 'E' and 'P' are evaluated from the following equations:

$$E = \frac{1}{2}C_{\rm sp}(\Delta V)^2 \tag{2}$$

$$P = \frac{E}{t_{\rm dis}} \tag{3}$$

Here,  $C_{\rm sp}$  indicates the specific capacitance of the active material, t indicates the discharging time and  $\Delta V$  indicates the potential window in 6 M KOH for charging and discharging. Different current energies and 'P' and specific capacitance for samples are presented in Table 2.

The relationship between 'E' and 'P', i.e., the Ragone plot for F1, F3, and F5 is illustrated in Fig. 8. According to Fig. 8, F3 obtained an 'E' of 33 W h kg<sup>-1</sup> at 'P' of 364.20 W kg<sup>-1</sup> and retained 9.60 W h kg<sup>-1</sup> at 2723.40 W kg<sup>-1</sup>, both of which are greater than that of recently published Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> symmetric supercapacitors in aqueous electrolyte.<sup>38</sup> The 'E' observed for sample F3 at a current density 0.5 A g<sup>-1</sup> is much higher than F1 and F5. The enhancement in the electrochemical properties in Fe<sub>2</sub>O<sub>3</sub>/Fe<sub>3</sub>O<sub>4</sub> sample (F3) may be due to lower internal resistance and better charge transport, which arises from the junction produced at the Fe<sub>3</sub>O<sub>4</sub>/Fe<sub>2</sub>O<sub>3</sub> interface than Fe<sub>2</sub>O<sub>3</sub> (F1) and Fe<sub>3</sub>O<sub>4</sub> (F5). These findings reveal that the synthesized F3 may

provide an excellent electrode material for supercapacitors with high power and low cost.

## Conclusions

Herein, a facile microwave-assisted solvothermal route for the synthesis of Fe<sub>3</sub>O<sub>4</sub>/Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, and Fe<sub>3</sub>O<sub>4</sub> nanoparticles having narrow size distribution with FeCl<sub>3</sub> as the iron source was investigated. The phase of the iron oxide was tuned by varying the EG to water ratio in the solvent. The prepared Fe<sub>3</sub>O<sub>4</sub>/ Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, and Fe<sub>3</sub>O<sub>4</sub> nanoparticles were studied for electrochemical application. The as-prepared Fe<sub>3</sub>O<sub>4</sub>/Fe<sub>2</sub>O<sub>3</sub> heterostructures demonstrated greater specific capacitances of 165 F g<sup>-1</sup> at the current density of 0.5 A g<sup>-1</sup> than Fe<sub>2</sub>O<sub>3</sub> and Fe<sub>3</sub>O<sub>4</sub>. In a nutshell, the findings of this study indicate that hematite might be used as an electrode material for high-performance supercapacitors.
