Electrochemical sensor for simultaneous determination of trifluoperazine and dopamine in human serum based on graphene oxide–carbon nanotubes/iron–nickel nanoparticles†

Yousef M. Ahmed, Mahmoud A. Eldin, Ahmed Galal  and Nada F. Atta *

Trifluoperazine (TFLP) is an important psychiatric medication that balances the dopamine (DA) level in the brain for patients suffering from neurological disorder diseases. An efficient electrochemical sensor is developed for detecting TFLP in real human serum samples. The sensor is fabricated by casting the GC surface with two consecutive thin layers, namely a graphene oxide–carbon nanotubes mixture (GRO–CNT), and iron–nickel nanoparticles (Fe–Ni). The diffusion-controlled oxidation process of TFLP at the composite surface includes one electron transfer process. Under optimized conditions, the sensor in human serum shows excellent catalytic effect for simultaneous determination of TFLP and dopamine (DA) in the same concentration range (0.5 μM to 18 μM) with low detection limits of 0.13 μM and 0.32 μM respectively. The combined effect of a large conductive surface area and the excellent catalytic activity of the nanocomposite improves the sensor's performance. The sensor exhibits a stable current response over four weeks, excellent reproducibility, and insignificant interference from common species present in human serum samples. The reliability test of using the sensor in serum samples shows good recovery of TFLP.

1. Introduction

Trifluoperazine (TFLP) belongs to the category of drugs called phenothiazine antipsychotics. It is a typical psychiatric medication that primarily treats schizophrenia.^{1,2} It is utilized for treating anxiety and controlling some psychotic disorders such as agitation, acute confusion state, depression, and psychosis.^{2,3} TFLP has central antiadrenergic and antidopaminergic effects. Besides, it is a dopamine (DA) antagonist, has an antipsychotic effect as it blocks DA – D1 and D2 receptors and prevents disorder illness effects such as hallucinations, delusions, disordered speech and thought resulting from DA excess in the brain.⁴ DA is an important neurotransmitter that belongs to the catecholamines family. DA is a substance released in the brain that helps to regulate mood, behavior, and thoughts. Thus, having the accurate amount of DA is important for both your brain and body. DA helps nerve cells to send messages to each other.⁵ Deficiency of DA in biological fluids can lead to various neurological disorders and diseases such as schizophrenia, bipolar disorder, tourette syndrome, and Parkinson's.⁶ Thus, TFLP is an important drug to balance the DA level in the brain

for patients suffering from neurological disorder diseases. To the best of our knowledge only one paper is cited for the determination of TFLP and DA in the literature.⁴ Also, simultaneous detection of DA and ascorbic acid (AA) using polymeric materials and metal nanoparticles-based sensors is cited in the literature.^{7,8} Some methods are utilized for TFLP detection such as reverse phase HPLC method, liquid chromatography–tandem mass spectrometry, spectrophotometry, flow injection fluorimetry.^{9–12} Low cost, simple operation, sensitivity, and fast response are the advantages of electrochemical methods over other cited methods.^{13,14}

Carbon nanotubes (CNTs) are made of concentric cylinders of graphite layers. CNTs are used to improve the thermal stability, hardness, and electrical conductivity of composites. CNTs have been used in sensing applications because of their large effective surface area, and excellent electrochemical properties.^{13,14} Besides, organic conjugated species can interact with the CNTs through π – π interactions and hydrophobic interactions.^{15,16}

Graphene oxide (GRO) is extensively used in chemical and biosensing applications because of its significant properties such as controllable electronic provisions, and surface defect density, hydrophilicity, and possession of various oxygen moieties.¹⁷ Furthermore, GRO can easily disperse in solvents and different matrices due to the presence of oxygen functionalities. Its mechanical and electrical properties are enhanced

† Electronic supplementary information (ESI) available. See DOI: <https://doi.org/10.1039/d3ra04334g>

when combining with different structures as CNTs and different catalysts. GRO acts as a support for various catalyst materials, which assists their spreading, and the stabilization of the resulting composites. The presence of reactive sites for binding and nucleation of different materials at the surface of GRO is due to edges of the sheets and the presence of sufficient functional groups on the GRO surfaces namely C–O–C, –OH, and –COOH.^{18,19} This results in speeding the electron transfer process between the analyte and the surface of the modified electrode.²⁰ Also, the homogeneous dispersion, conductivity, electrocatalytic behavior, and chemical stability can be improved by the addition of carbon material to metal oxides.²¹ Besides, electrochemical detection of diverse molecules was achieved at GRO derivatives-based nanocomposites.^{22,23}

Bimetallic nanoparticles consist of two metal components. The enhancement in their catalytic capabilities gives them a significant advantage over monometallic nanoparticles. Bimetallic nanoparticles catalysts boost stability, catalytic activity, and selectivity in electrochemical applications. Bimetallic nanoparticles exhibit a wide range of intriguing size-dependent chemical, electrical, and optical characteristics.²⁴ Besides, use of bimetallic nanoparticles in the fabricated sensors prevents catalyst poisoning. The iron–nickel alloy is considered as a promising contender for numerous applications because of its significant features such as great corrosion resistance, ferromagnetism, thermal stability, hardness, ductility, thermal expansion, and catalytic activity.^{25–27} The nickel–iron alloy exhibits a definite structure where the weight percentage of Ni ranges from 35% to 80%. The improvement in the catalytic activity of the Fe–Ni is due to variations in their system electron density and in the length of metal–metal bond.^{28,29}

Also, nanostructure materials and different bimetallic nanoparticles are used for modifying the electrode composite surfaces for sensing applications.^{30–32}

Thus, the outstanding synergism between the modifiers; CNTs, GRO and iron–nickel nanoparticles with their distinctive characteristics, enhances the electrochemical current response for TFLP. GRO sheets with large surface area act as support for Fe–Ni nanoparticles and assist their homogeneous distribution and the stabilization of the resulting composite. Besides, the presence of reactive sites for the binding and nucleation of target species at its surface is due to the presence of several functional groups. CNTs offer large effective surface area, high edge plane/basal plane ratio, high sorption capacity, penetration ability, surface adsorption and excellent electrical conductivity. Further, the incorporated CNTs can serve as an electrical conducting network between the GRO sheets, they greatly facilitate the electrochemical oxidation of TFLP. Further, the high permeability of nickel–iron alloys make them very useful materials for electronic conduction. The Fe–Ni nanoparticles with excellent catalytic activity create a conduction pathway in the modified composite, act as an electron transfer medium, and enhance the electron transfer during the electrochemical oxidation reaction.

In the present work, a novel modified sensor GC/GRO-CNT/Fe–Ni is fabricated by casting the GC surface with two

consecutive thin layers from graphene oxide–carbon nanotubes mixture (GRO-CNT), and iron–nickel nanoparticles (Fe–Ni). This increases the composite surface area, the contact area with the TFLP species and improves the electrocatalytic behavior of the composite toward oxidation of TFLP. Under optimized conditions, the sensor in human serum shows excellent catalytic effect for simultaneous determination of TFLP and dopamine (DA) in the same concentration range (0.5 μM to 18 μM) with low detection limits 0.13 μM and 0.32 μM respectively. The combined effect of large conductive surface area and excellent catalytic activity of GRO-CNT/Fe–Ni nanocomposite improves the sensor's performance. The GC/GRO-CNT/Fe–Ni modified electrode offers good sensitivity and low detection limit for TFLP compared to other modified electrodes cited in the literature. Good reproducibility, repeatability and perfect storage stability are the features of the sensor. The TFLP sensor exhibits excellent selectivity, and insignificant interference from common species present in human serum samples. Acceptable recovery is obtained for practical application of the sensor in human serum samples for TFLP determination.

2. Experimental section

2.1 Chemicals

CNTs (>90% carbon basis, OD/ID \times L: 10–15 nm/2–6 nm \times 0.1–10 μm), graphite powder, Fe–Ni nanoparticles, H_2SO_4 , P_2O_5 , $\text{K}_2\text{S}_2\text{O}_8$, H_2O_2 , KMnO_4 , DMF, ascorbic acid (AA), uric acid (UA), paracetamol (PAR), dopamine (DA), serotonin (ST), KH_2PO_4 , K_2HPO_4 , H_3PO_4 , and KOH are purchased from Sigma-Aldrich Chem. Co. (Milwaukee, WI, USA). Trifluoperazine (TFLP) and ibuprofen (IBU) are provided by the National Organization for Drug Control. ESI Table 1† summarizes the devices used in this work.

2.2 Preparation of tested samples

We examined the applicability of GC/GRO-CNT/Fe–Ni modified electrode for sensing TFLP in samples of real human serum. The serum samples are prepared as mentioned elsewhere.²⁸ Under optimal experimental conditions we studied the recovery test of TFLP using differential pulse voltammetry (DPV) mode in diluted serum samples (diluted five times with PBS). The specific concentrations of TFLP are prepared from 1.0 mM TFLP stock solution/0.1 M PBS solution (pH 7.0) and spiked in diluted serum sample.

2.3 Preparation of GRO

Graphene oxide is prepared by modified Hummer's method, briefly, 5 g of high purity graphite is cured with H_2SO_4 , P_2O_5 and $\text{K}_2\text{S}_2\text{O}_8$ to prepare the pre-oxidized graphite. This is followed by stirring 5 g of dried pre-oxidized graphite with 115 mL of concentrated H_2SO_4 in an ice bath for 10 minutes. After that, 15 g of KMnO_4 is gradually added and stirred for two hours. The mixture acquired a bright yellow color after dilution with water and treatment with H_2O_2 . The bright yellow suspension is filtered and washed with 1 : 10 (v/v) HCl-solution, and finally dried overnight in an oven at 80 $^\circ\text{C}$.³³

2.4 Preparation of the TFLP sensor

The GC/GRO-CNT/Fe-Ni sensor (Scheme 1) is prepared as follows: 10 μL from a suspension mixture of (0.5 mg GRO-0.5 mg CNT/1 mL DMF) (optimized) is cast over the GC electrode surface then the electrode is dried in oven at 50 $^{\circ}\text{C}$ for 10 min. 10.0 μL of well-dispersed Fe-Ni nanoparticles (1.5 mg of Fe-Ni/1.0 mL DMF) (optimized) is drop-cast over the previous modified surface GC/GRO-CNT. The GC/GRO-CNT/Fe-Ni electrode is left to dry in oven for 10 min at 50 $^{\circ}\text{C}$. Optimization of the fabricated sensor is shown in ESI Fig. 1A and B.†

Electrochemical effective surface areas of the studied electrodes were calculated by running CV experiments in 1.0 mM $\text{K}_3[\text{Fe}(\text{CN})_6]$ system as mentioned elsewhere.¹⁴ The areas for GC/CNT, GC/GRO-CNT and GC/GRO-CNT/Fe-Ni electrodes are found to be 0.1019 cm^2 , 0.129 cm^2 and 0.136 cm^2 , respectively, ESI Fig. 2A–C.†

3. Results and discussion

3.1 Surface characterization of the modified electrodes

The GC/GRO-CNT and GC/GRO-CNT/Fe-Ni are characterized using scanning electron microscopy (SEM) and transmission electron microscope (TEM). Fig. 1A shows the SEM image of GRO-CNT composite where the graphene oxide sheets are entirely mixed with CNTs. GRO sheets morphology are characterized by thick flat flake layers, rough surfaces, and irregular shapes. Disordered and unwrinkled structured were owing to the existence of oxygen atoms.³⁴ GRO sheets are entirely wrapped by the tubular networks of CNTs *via* noncovalent π - π stacking interactions. Fig. 1B shows the GRO sheets are completely embedded in the CNTs matrix with good distribution of the spherical Fe-Ni nanoparticles over the GC/GRO-CNT composite surface. The incorporated CNTs can serve as an electrical conducting network for GRO sheets, which significantly facilitate the electrochemical oxidation of TFLP. Fig. 1C shows higher magnification of the sensor surface where it illustrates the morphology of the GRO-

CNT/Fe-Ni composite matrix. Further, the structural morphologies of GRO-CNT and GRO-CNT/Fe-Ni composites are characterized by HR-TEM analysis, Fig. 1D illustrates the image of GRO-CNT composite where the GRO sheets are mixed with CNTs. Fig. 1E illustrates the image of GRO-CNT/Fe-Ni composite where the Fe-Ni nanoparticles, spherical-like morphology, assembled over the CNTs mixed with GRO. Fig. 1F and G show the EDX and the elemental mapping of GC/GRO-CNT/Fe-Ni, confirming the

presence of all the elements included in the nanocomposite. The following elements are identified with their relative weight percentages as follows C: 34.58%; O: 2.71%; Ni: 29.67%; Fe: 33.04%. Selected area electron diffraction (SAED) patterns Fig. 1H and I are obtained from the corresponding areas in Fig. 1D and E.

3.2 Electrochemistry of the modified electrodes

The catalytic activity of the different working electrodes towards the electrochemical oxidation of 1.0 mM TFLP/0.1 M PBS/pH 7.0 is studied. Cyclic voltammetry (CV) is performed to compare the electrochemical sensing performance of bare GC and different modified working electrodes: bare GC, GC/GRO, GC/CNT, GC/GRO-CNT, and GC/GRO-CNT/Fe-Ni (Fig. 2). The bare GC electrode and the modified electrode GC/GRO show poor current responses of oxidation peaks with the values 36.4 μ A, 27.7 μ A at 639 mV and 772 mV, respectively. Using GC/CNT, and GC/GRO-CNT electrodes higher current responses of oxidation peaks with the values 107.0 μ A, 280 μ A at 732 mV, and 771 mV, respectively are obtained. One electron is involved in the TFLP irreversible oxidation process. Further modification of the GC/GRO-CNT electrode surface with a thin film of Fe-Ni nanoparticles improves the peak sharpness and increases the oxidation peak current up to 556 μ A at 845 mV. This is due to the good synergism between the components of the nanocomposite GRO-CNT/Fe-Ni. Thus, the sensor shows kinetic enhancement in the oxidation of TFLP. The observed results are summarized as follows: GRO sheets with large surface area act as support for Fe-Ni nanoparticles and assist their homogeneous distribution and the stabilization of the resulting composite. Besides, the presence of reactive sites for the binding and nucleation of target species at its surface is due to the presence of several functional groups. CNTs offer large effective surface area, and excellent electrical conductivity. Further, the incorporated CNTs can serve as an electrical conducting network between the GRO sheets, they greatly facilitate the electrochemical oxidation of TFLP. Further, the Fe-Ni nanoparticles with excellent catalytic activity create a conduction pathway in the modified composite, act as an

electron transfer medium, and enhance the electron transfer during the electrochemical oxidation reaction.

3.3 Effect of scan rate

CV is used to study the effect of applying different scan rates (10–100 mV s^{-1}) on the oxidation peak current of 1.0 mM TFLP/0.1 M PBS/pH 7.0 using the optimized sensor as shown in ESI Fig. 3.† Scan rate is studied to examine the number of electrons transferred during the TFLP oxidation process. The oxidation current increases with increasing the scan rate with positive shift in the oxidation potential. The inset shows the linear regression relationship of peak oxidation current (I_p) vs. square root of scan rate, and can be expressed with eqn (1):

$$I_p (\mu\text{A}) = -155 + 76.4v^{\frac{1}{2}} (\text{mV s}^{-1})^{\frac{1}{2}} (R^2 = 0.995) \quad (1)$$

The linear relationship of I_p versus $v^{\frac{1}{2}}$ indicates that the oxidation process is a diffusion-controlled electron transfer process.

3.4 Effect of pH

The pH of the buffer solution has an important effect on both the oxidation potential and current of TFLP. CV is used to study the pH-dependent behavior of 1.0 mM TFLP oxidation (Fig. 3). The oxidation peak current (I_p) increases with pH up to 7.0, then there is a decrease in current as shown in (Fig. 3; inset A). Fig. 3; inset B represents the variation of peak oxidation potential (E_p) as a function of electrolyte pH, the oxidation peak potential decreases with an increase in pH. The pK_a value of TFLP compound is 8.1, it is protonated at low pH.³⁵ In acidic media at (pH = 3, 5) two-steps oxidation of TFLP is favored³⁶ as it appeared as two oxidation peaks but at pH = 7.0, a one-step oxidation is favored, and one oxidation peak appeared (Fig. 3).³⁷ The TFLP contains a tertiary amine in its molecular structure, this is a basic center with the availability of non-

Fig. 2 CVs of 1.0 mM TFLP/0.1 M PBS (pH 7.0), the scan rate is 50 mV s^{-1} using different modified electrodes.

Fig. 3 CVs of 1.0 mM TFLP/0.1 M PBS with different pH; scan rate is 50 mV s^{-1} using GC/GRO-CNT/Fe-Ni electrode. (Inset A) Relation between oxidation peak current and pH. (Inset B) Relation between oxidation peak potential and pH.

bonding electrons as donor. So, it can be assumed that oxidation is located on the nitrogen of the piperazine ring.³⁸ In acidic medium at (pH = 3, 5), it loses an electron to form a cation radical and this cation radical loses a proton and electron in subsequent steps to form a quaternary Schiff base.³⁹ The quaternary Schiff base was rapidly hydrolyzed to the secondary amine and formaldehyde.

To identify the responsible group of the oxidation steps, the oxidation of TFLP was compared with some model compounds in the literature such as trazodone, flunarizine, nefazodone, quetiapine, and sildenafil citrate.^{38,40–43} For all the compounds, oxidation is included in the piperazine ring which suggests an identical mechanism. For an example the oxidation steps of nefazodone are located on the piperazine moiety, which represents a typical redox system with two electron oxidation processes in acidic and basic media.³⁸ We may postulate that when the aliphatic nitrogen of the piperazine moiety, at a relative long distance from the benzene ring of the molecule, is protonated, oxidation occurs on the nearer nitrogen. This mechanism and all the obtained results agree with reported data concerning anodic voltammetry of trazodone at glassy carbon and carbon paste electrodes.³⁸ Nefazodone, piribedil, and trazodone are oxidized over most of the pH range in a single peak. The peak potentials shift with increasing pH to less positive potentials similarly as the potential of quetiapine, and became pH-independent at pH higher than 6.0.⁴² In sildenafil citrate the monoprotonated form of the piperazine ring is oxidized at pH < 6.0 with the same mechanism.^{41,43} At pH = 7.0, one oxidation peak is obtained because of one-step oxidation (Fig. 3). Thus, at pH = 7.0 one electron is involved in the oxidation of TFLP (the N-atom in phenothiazine ring converted to cationic radical N-atom).³⁷ At pH > 7.0 the current decreases as the protonation degree decreases with increasing pH, TFLP becomes neutral, and its accumulation at the composite surface becomes difficult.⁴⁴ Thus, PBS of pH 7.0 is used for sensing TFLP in this work.

3.5 Reproducibility and stability

The current responses of 1.0 mM TFLP/0.1 M PBS/pH 7.0 at three different electrodes prepared independently under similar construction conditions are investigated to determine the fabrication reproducibility of the sensor. Acceptable fabrication reproducibility is obtained as the value of RSD is 2.32%. CV is used to examine the current response stability of the sensor toward TFLP oxidation. The sensor shows good stability after 25 runs in 1.0 mM TFLP as shown in ESI Fig. 4,† and for long term stability of one month, the electrochemical response of the electrode maintains 95.8% of its initial current value. Thus, the current response stability of the sensor is attributed to the composite materials stability.

3.6 Robustness

The robustness of this method is evaluated upon the impact of minor alterations in the experimental conditions. The studied parameters are time before running the experiment (2 minutes ± 20 s) and pH change (7.0 ± 0.2). The relative standard

deviations are 1.33% and 2.46%, respectively confirm the steadiness of the current response stability.

3.6.1 Voltametric determination of TFLP. In this section we apply DPV mode for the determination of TFLP in diluted serum samples using the GC/GRO-CNT/Fe–Ni electrode. After increasing concentration of TFLP in diluted serum sample, typical voltammograms are obtained with the increase of TFLP concentration in the range (0.008 μM to 24 μM) as shown in (Fig. 4; inset). According to ICH guidelines the proposed method is validated with respect to linearity, detection limit (DL), and quantification limit (QL).⁴⁵ Fig. 4 indicates the obtained linear range covered the TFLP concentration from 0.008 μM to 24 μM. The corresponding regression eqn (2) is:

$$I_p (\mu A) = 3.602C (\mu M) + 8.027, R^2 = 0.998 \quad (2)$$

The DL and QL are 1.06 nM and 3.52 nM, respectively. DL and QL are determined according to (S/N = 3).⁴⁶ The performance of the sensor for TFLP detection is compared with other cited modified sensors.^{2,3,37,44,47–49} The sensor offers reasonable linear range for TFLP detection, DL lower than other used modified electrodes with good stability and accuracy as illustrated in ESI Table 2.† Thus, the sensor can be acceptably applied for the determination of TFLP levels in serum samples.

3.6.2 Simultaneous determination of TFLP and DA. Trifluoperazine is a medication that monitors dopamine levels in the brain. TFLP is antipsychotic medication that works by blocking dopamine receptors, which helps in improving symptoms of certain mental health conditions such as schizophrenia. Besides, it prevents disorder illness effects such as hallucinations, delusions, disordered speech and thought resulting from DA excess in the brain. Thus, it is important to study the simultaneous determination of DA and TFLP in their mixture using the GC/GRO-CNT/Fe–Ni modified electrode. Highly resolved oxidation signals of DA

Fig. 4 Calibration of TFLP (concentration range: 0.008 μM to 24 μM) in diluted serum/0.1 M PBS (pH 7.0); inset: the corresponding DPVs using GC/GRO-CNT/Fe–Ni electrode.

Fig. 5 (A) DPVs of simultaneous determination of DA and TFLP in the same concentration range from 0.5 μM to 18 μM in diluted serum/0.1 M PBS pH 7.0; inset: the corresponding calibration curve for DA and TFLP. (B) DPVs of TFLP (concentration range from 2 μM to 25 μM) in presence of constant concentration 14 μM of DA in diluted serum/0.1 M PBS pH 7.0; inset: the corresponding calibration curve for TFLP. (C) DPVs of DA (concentration range from 0.8 μM to 14 μM) in presence of constant concentration 2 μM of TFLP in diluted serum/0.1 M PBS pH 7.0; inset: the corresponding calibration curve for DA.

and TFLP with large potential separation between their oxidation peaks are obtained as shown in Fig. 5A. Fig. 5A; insets show that the oxidation current responses of the two studied compounds increased linearly with increasing their corresponding concentrations in the same range (0.5 \rightarrow 18 μM). The linear regression eqn (3) and (4) are as follows:

$$I_p (\mu\text{A}) = 2.932C_{\text{DA}} (\mu\text{M}) + 2.896, (R^2 = 0.990) \quad (3)$$

$$I_p (\mu\text{A}) = 2.268C_{\text{TFLP}} (\mu\text{M}) + 12.05, (R^2 = 0.995) \quad (4)$$

The DLs are 0.13 μM and 0.32 μM , respectively.

Another electroanalytical study is performed to evaluate the possible mutual interference from separation of a mixture of DA and TFLP. In this part we investigate whether the presence of one compound affects the detection of another compound. The concentration of TFLP compound is changed in the range (2 \rightarrow 25 μM) while the concentration of DA compound is remained constant at (14 μM) as shown in Fig. 5B. The TFLP peak current responses increased linearly with the increase of its corresponding concentrations (Fig. 5B; inset). The regression eqn (5) for the linear relation of TFLP is:

$$I_p (\mu\text{A}) = 2.297C_{\text{TFLP}} (\mu\text{M}) + 23.4, (R^2 = 0.992) \quad (5)$$

Fig. 5C shows another study for TFLP and DA, the concentration of TFLP is remained constant at (2 μM) and the DA concentration is changed in the range (0.8 \rightarrow 14 μM). The DA peak current responses increased linearly with the increase of its corresponding concentrations (Fig. 5C; inset). The regression eqn (6) for the linear relation of DA is:

$$I_p (\mu\text{A}) = 2.374C_{\text{DA}} (\mu\text{M}) + 7.808, (R^2 = 0.995) \quad (6)$$

3.7 Recovery

Recovery experiments are carried out by standard additions of TFLP in diluted human serum sample to study the accuracy of the proposed method. By comparing the calculated concentrations for the studied sample (from calibration curve) with the added concentrations, the recovery percentages are determined. The analysis for each added concentration in the sample is repeated three times. Table 1 lists the obtained results. The recovery and RSD values are in the range of (99.04% to 102.7%) and (0.72% to 1.6%) respectively, demonstrating a good accuracy of the used method.

3.8 Determination of TFLP in pharmaceutical samples

In this section we evaluate the proposed method for the determination of pure TFLP content in commercial capsules without interference from excipient materials. An oral capsule containing TFLP (5 mg per capsule) is ground into fine powder and then dissolved in a buffer solution (pH 7.0) with a starting concentration of 0.5 mM. The TFLP amount in the sample solution is determined by the addition method. In the electrolytic cell we inject a standard with concentration 2.0 μM by micro-syringe.

Then aliquots of the TFLP capsule sample solution are prepared with concentrations ranging from 0.5 μM to 8.0 μM and injected into the electrolytic cell. We use the following equation to calculate the concentration of the sample: [standard (2 μM)] + [capsule content solution added (0.5 μM to 8.0 μM)]. DPV mode is used to estimate the percentage values of recovery. The found concentrations are calculated from the average of three repeated measurements for every added amount and are summarized in Table 2. The corresponding recovery values are in the range (97.70%–102.4%) and the RSD values are in the range (0.120%–1.917%) for quantitative determination of TFLP in commercial capsule samples, indicating that the proposed method has a good accuracy.

3.9 Interference study

3.9.1 In presence of paracetamol. The determination of TFLP and paracetamol (PAR) is important for patients taken pain reliever drug. PAR is a common pain reliever and fever reducer, while TFLP is antipsychotic medication. Accurate determination of the level of TFLP without interference from PAR in patient's biological fluids can help patients to monitor the appropriate dose and avoid potential side effects or adverse reactions. Fig. 6A shows non-interfered change in the TFLP oxidation peak current responses as its concentration changed in the range (2 \rightarrow 20 μM) while the concentration of PAR is remained constant at (4 μM). The TFLP peak current responses increased linearly with the increase of its corresponding concentrations (Fig. 6A; inset). The regression eqn (7) for the linear relation of TFLP is:

$$I_p (\mu\text{A}) = 2.815C_{\text{TFLP}} (\mu\text{M}) + 14.31, (R^2 = 0.991) \quad (7)$$

3.9.2 In presence of different interfering species. It is necessary to examine the ability of the proposed sensor to

selectively and simultaneously discriminate between the studied drug and the interfering species present in the human fluids. Ascorbic acid (AA) and uric acid (UA) are two common interfering species that can be found in human body fluids. AA and UA can interfere with the accurate detection of other studied compounds. Therefore, it is important to consider and address their potential influence when developing a proposed method for detecting TFLP drug in biological samples.

Ibuprofen is a nonsteroidal anti-inflammatory drug commonly used to relieve pain, reduce fever, and decrease inflammation. Fig. 6B shows five separated and clearly defined oxidation peaks for a quinary mixture of AA, DA, UA, TFLP and IBU. The concentrations are as follows: AA (800 μM), DA (8 μM), UA (12 μM), TFLP (2 μM), and IBU (24 μM). Simultaneous detection of these species is successfully achieved. Further, monitoring the level of the TFLP drug in presence of other species can aid in the diagnosis and treatment of certain medical conditions.

It is important to measure the dopamine level in the presence of TFLP. This measurement can help evaluate the effectiveness of TFLP in treating mental health conditions such as schizophrenia, which is resulted from imbalance of dopamine and other neurotransmitters such as serotonin. Therefore, using an electrochemical sensor can be a useful tool in developing an effective treatment for patients with mental health conditions such as dopamine dysregulation.

Fig. 6C indicates the DPV pattern of a ternary mixture containing 10 μM DA, 20 μM ST, and 3 μM TFLP analyzed at two different types of electrodes: GC/GRO-CNT/Fe–Ni and GC/CNT. At the GC/GRO-CNT/Fe–Ni sensor, three separated and clearly defined oxidation peaks are observed however, at the GC/CNT electrode, overlapped and undefined peaks are obtained. This demonstrates that the GC/GRO-CNT/Fe–Ni electrode is effective in separating and detecting the individual components of the ternary mixture compared to the GC/CNT electrode.

Fig. 6 (A) DPVs of TFLP (concentration range from 2 μM to 20 μM) in presence of constant concentration 4 μM of PAR in 0.1 M PBS pH 7.0; inset: the corresponding calibration curve for TFLP. (B) DPV of quinary mixture containing AA (800 μM), DA (8 μM), UA (12 μM), TFLP (2 μM), and IBU (24 μM) at GC/GRO-CNT/Fe-Ni in 0.1 M PBS/pH 7.0. (C) DPVs of ternary mixture containing 10 μM DA, 20 μM ST and 3 μM TFLP at GC/CNT, and GC/GRO-CNT/Fe-Ni in 0.1 M PBS/pH 7.0.

4. Conclusions

A novel electrochemical method is applied to determine TFLP and DA in real human serum samples. The sensor is

constructed by casting two consecutive thin layers of GRO-CNT and Fe-Ni nanoparticles over a GC electrode surface. This increases the composite surface area, the contact area with the TFLP drug, and improves the electrocatalytic behavior of the composite. Thus, good synergism between the components of the GRO-CNT/Fe-Ni nanocomposite improves the performance of the sensor. The significant enhancement in the sensitivity of the GRO-CNT/Fe-Ni nanocomposite towards TFLP determination results in enhancement of the kinetic process and increase of the oxidation peak current up to 556 μA . The sensor in serum sample shows excellent catalytic effect for simultaneous determination of TFLP and DA in the same concentration range (0.5 \rightarrow 18 μM) with low DLs 0.13 μM and 0.32 μM respectively. Moreover, the constructed sensor displays excellent reproducibility, good sensitivity, acceptable stability, and suitable recovery for TFLP in serum samples. Further, the sensor is capable of reliably detecting TFLP in clinical trial samples and pharmaceutical formulations.

Conflicts of interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.
