# Enhancing the electrocatalytic performance of $\text{SnX}_2$ ( $\text{X} = \text{S}$ and $\text{Se}$ ) monolayers for $\text{CO}_2$ reduction to $\text{HCOOH}$ via transition metal atom adsorption: a theoretical investigation†

Feifei Xia,  Qing Xu, Fengli Yang, Li Shu and Yingpin Wen

Exploring highly efficient, stable, and low-cost electrocatalysts for  $\text{CO}_2$  reduction reaction (CRR) can not only mitigate greenhouse gas emission but also store renewable energy. Herein,  $\text{CO}_2$  electroreduction to  $\text{HCOOH}$  on the surface of  $\text{SnX}_2$  ( $\text{X} = \text{S}$  and  $\text{Se}$ ) monolayer-supported non-noble metal atoms ( $\text{Fe}$ ,  $\text{Co}$  and  $\text{Ni}$ ) was systematically investigated using first-principles calculations. Our results show that  $\text{Fe}$ ,  $\text{Co}$  and  $\text{Ni}$  adsorbed on the surface of  $\text{SnX}_2$  ( $\text{X} = \text{S}$  and  $\text{Se}$ ) monolayers can effectively enhance their electrocatalytic activity for  $\text{CO}_2$  reduction to  $\text{HCOOH}$  with low limiting potentials due to the decreasing energy barrier of  $^*\text{OOCH}$ . Moreover, the lower free energy of the  $^*\text{OOCH}$  intermediate on the surface of  $\text{TM}/\text{SnX}_2$  ( $\text{X} = \text{S}$  and  $\text{Se}$ ) monolayers verifies that the electroreduction of  $\text{CO}_2$  to  $\text{HCOOH}$  prefers to proceed along the path:  $\text{CO}_2 \rightarrow ^*\text{OOCH} \rightarrow ^*\text{HCOOH} \rightarrow \text{HCOOH}$ . Interestingly,  $\text{SnX}_2$  ( $\text{X} = \text{S}$  and  $\text{Se}$ ) monolayer-supported  $\text{Co}$  and  $\text{Ni}$  atoms prefer the  $\text{HCOOH}$  product with low CRR overpotentials of 0.03/0.01 V and 0.13/0.05 V, respectively, showing remarkable catalytic performance. This work reveals an efficient strategy to enhance the electrocatalytic performance of  $\text{SnX}_2$  ( $\text{X} = \text{S}$  and  $\text{Se}$ ) monolayers for  $\text{CO}_2$  reduction to  $\text{HCOOH}$ , which could provide a way to design and develop new CRR catalysts experimentally in future.

## 1. Introduction

Nowadays, the greenhouse effect and energy shortage have become more serious with the rapid worldwide economic expansion, and threaten the survival and development of mankind.<sup>1,2</sup> So mitigating  $\text{CO}_2$  emissions and converting  $\text{CO}_2$  into valuable products have attracted great research attention due to the potential impact on energy storage and recycling resources.<sup>3</sup> The electrocatalytic  $\text{CO}_2$  reduction reaction (CRR) has been widely studied experimentally and theoretically,<sup>4–10</sup> which not only reduces  $\text{CO}_2$  emissions but also simultaneously produces valuable chemicals, such as the main C1 products  $\text{HCOOH}$ ,  $\text{CO}$ ,  $\text{CH}_3\text{OH}$  and  $\text{CH}_4$ . However, it is challenging to explore efficient electrocatalysts to improve the exothermic CRR process due to the inert nature of  $\text{CO}_2$ .<sup>11,12</sup> In addition, there are some severe bottleneck issues in the process of CRR, such as various intermediates and many reduction reaction pathways, leading to poor product selectivity as well as loss of efficiency toward the competing hydrogen evolution.<sup>13–15</sup> Therefore, it is very necessary to design and synthesize electrocatalysts with

high product selectivity, low limiting potential and eminent catalytic performance for CRR.

It has been reported that  $\text{Sn}$ -based catalysts have been found with superior performance toward CRR because of their high activity and selectivity.<sup>8,9,16–25</sup> Generally, the  $^*\text{OOCH}$  intermediate is more favorable for  $\text{Sn}$ -based catalysts during CRR because  $\text{CO}_2$  prefers to form a bidentate  $\text{O-Sn}$  adsorption configuration on  $\text{Sn}$  sites, which results in the  $\text{HCOOH}$  product, corresponding to a two-electron transfer mechanism. For example, Guan *et al.*<sup>8,9</sup> fabricated metal tin and tin oxides catalysts by different electrodeposition methods and revealed that these catalysts had efficient catalytic ability for  $\text{CO}_2$  electroreduction to  $\text{HCOOH}$ . Geng *et al.*<sup>22</sup> demonstrated the catalytic activity of  $\text{SnS}_2$  nanosheets for CRR was obviously enhanced by surface hydrogen incorporation, which decreases the energy barrier of  $^*\text{OOCH}$  intermediate formation and is in favor of  $\text{HCOOH}$  product. He *et al.*<sup>24</sup> synthesized a  $\text{SnSe}_2@\text{CC}$  electrocatalyst that is high selectivity and catalytic activity towards  $\text{HCOOH}$  production. All these reported works show that the catalytic performance of two-dimensional (2D)  $\text{SnX}_2$  ( $\text{X} = \text{S}$  and  $\text{Se}$ ) for CRR can be modulated by surface modification.

In the other hand, single-atom catalysts (SACs) are prospective CRR electrocatalysts because SACs characterized by an isolated metal atom supported on the solid surface play important roles in activating substrate materials.<sup>26–32</sup> For

School of Chemistry and Chemical Engineering, Jiangsu University of Technology, Changzhou 213001, Jiangsu, P. R. China. E-mail: ffxia@jsut.edu.cn

† Electronic supplementary information (ESI) available. See DOI: <https://doi.org/10.1039/d3ra06692d>

example, Xie *et al.*<sup>28</sup> reported that Co atoms on the surface of atomically thin layers prefer to form \*OOCH intermediate during CRR with higher activity and selectivity towards HCOOH product. Zheng and co-workers<sup>29</sup> synthesized a low-cost carbon nanoparticle supported Ni single atoms *via* a simple and scalable method, which is high selective and active toward CO production. Moreover, 2D materials supported transition metal (TM) atoms have been supposed as efficient electrocatalyst for CRR due to their large surface-to-volume ratio, tunable electronic structures and strong coordinating capability.<sup>30–32</sup> Thus, inspired by these reported works, whether TM atoms anchored on the surface of SnX<sub>2</sub> (X = S and Se) monolayers could also improve the catalytic performance of these monolayers for CRR or not, which is necessary to gain an insight into the relationship between the TM atoms and SnX<sub>2</sub> (X = S and Se) monolayers and screens out the optimal electrocatalysts for HCOOH production.

Herein, the SnX<sub>2</sub> (X = S and Se) monolayers before and after supported Fe, Co and Ni atoms for CO<sub>2</sub> electroreduction to HCOOH were systematically investigated by first-principles calculation based on density functional theory (DFT)<sup>33,34</sup> in the work. Considering the competition of hydrogen evolution reaction (HER) and CRR, the Gibbs free energies of \*H, \*COOH and \*OOCH intermediates were calculated, which is plotted by  $\Delta G_{*COOH/*OOCH}$  versus  $\Delta G_{*H}$ . The results show that SnX<sub>2</sub> (X = S and Se) monolayers supported Fe, Co and Ni atoms tend to form \*OOCH intermediate, leading to the HCOOH production. Moreover, the overpotential and limiting potential calculations revealed that the electrocatalytic performance of SnX<sub>2</sub> (X = S and Se) monolayers for CO<sub>2</sub> reduction to HCOOH can be obviously improved by adsorption of Fe, Co and Ni atoms. Especially, Co and Ni anchored on SnX<sub>2</sub> (X = S and Se) monolayers for HCOOH production with the lower overpotentials and limiting potentials, corresponding to the potential determining step of \*+ CO<sub>2</sub> → \*CO<sub>2</sub>. Our calculated results are beneficial to synthesize more efficient CRR catalysts in future, which would provide a perspective on the phenomena observed in the experiment.

## 2. Computational methods

All the geometry optimization and energy calculations were performed using the Vienna *ab initio* simulation package (VASP)<sup>35,36</sup> based on the DFT with the Perdew–Burke–Ernzerhof (PBE) functional for generalized gradient approximation (GGA)<sup>37–39</sup> to characterize the electron exchange and correlation effects. The van der Waals interaction was described in Grimme's scheme (DFT-D3).<sup>40</sup> A cutoff energy of 500 eV was used for the plane-wave basis set, and the energy and force convergence criteria were set to 10<sup>−6</sup> eV and 0.01 eV Å<sup>−1</sup>, respectively. The vacuum space of 18 Å was chosen to avoid the interaction between the periodical images. Brillouin zone sampling is performed with Monkhorst–Pack special *k*-point meshes,<sup>41</sup> and the 6 × 6 × 1 *k*-grid was chosen for the geometry optimization of SnX<sub>2</sub> (X = S and Se) monolayers.

The adsorption energy ( $E_{\text{ads}}$ ) of reaction intermediate (A) on the surface of different SnX<sub>2</sub> (X = S and Se) monolayers was defined as:

$$E_{\text{ads}} = E_{*_{\text{adsorbate}}} - E^* - E_{\text{adsorbate}} \quad (1)$$

where  $E_{*_{\text{adsorbate}}}$ ,  $E^*$  and  $E_{\text{adsorbate}}$  are the total energy of the adsorbate on the surface of catalyst, the catalyst and the adsorbate, respectively.

Free energies of the CRR intermediates in electrochemical reaction pathways were evaluated according to the computational hydrogen electrode (CHE) model developed by Nørskov *et al.*<sup>42,43</sup> using the reversible hydrogen electrode (RHE) as a reference which chemical potential of ( $\text{H}^+ + \text{e}^-$ ) is equivalent to that of 1/2H<sub>2</sub> at 0 V and at all pH values. In the acidic condition, the mechanism of CO<sub>2</sub> reduction to HCOOH is generally regarded as the following steps:<sup>8,9</sup>

Thus, the Gibbs free energies of each intermediate were calculated as:<sup>42</sup>

$$\Delta G = \Delta E - \Delta E_{\text{ZPE}} - T\Delta S + \Delta G_U + \Delta G_{\text{pH}} \quad (6)$$

where  $\Delta E$ ,  $\Delta E_{\text{ZPE}}$  and  $T\Delta S$  are the total calculated energies, zero-point energy corrections and entropy contributions at 298.15 K, respectively.  $\Delta G_U$  is the free energy change of electrode potential ( $U$ ).  $\Delta G_{\text{pH}}$  is the free energy correction relating to the solution pH (in this paper pH = 0 for acidic medium). The less negative limiting potential ( $U_L$ ), the higher activity and selectivity of the catalysts, so  $U_L$  determined by the potential determining steps (PDS) is obtained from the free energy change ( $\Delta G_{\text{MAX}}$ ) by using the relation  $U_L = -\Delta G_{\text{MAX}}/ne$ . Moreover, the overpotential ( $\eta$ ) is calculated to evaluate the catalytic performance of different SnX<sub>2</sub> (X = S and Se) monolayers, which is the difference between the equilibrium potential ( $U_e$ ) and  $U_L$ . The vibrational frequency of intermediates for CRR by VASPKIT software that is a pre and post-processing program.<sup>44</sup>

## 3. Results and discussion

### 3.1 Adsorption of \*H, \*COOH and \*OOCH

It is well known that the hydrogen evolution reaction (HER) is a competitive reaction during the process of CRR on the most of metal catalysts due to the selectivity of first protonation step.<sup>45,46</sup> Therefore, we firstly calculated the \*H, \*COOH and \*OOCH intermediates adsorption on the surface of SnX<sub>2</sub> (X = S and Se) monolayers, and the corresponding optimized energy favorable structures are presented in Fig. 1 and S1.† In accordance with our previous work,<sup>47</sup> the transition metal

Fig. 1 Side and top views of key intermediates (\*H, \*COOH and \*OOCH) adsorption on the surface of (a–c) pristine  $\text{SnS}_2$  and (d–f) TM/ $\text{SnS}_2$  monolayers.

atoms (Fe, Co and Ni) also prefer to anchor on the six-member ring (hollow) site of  $\text{SnSe}_2$  monolayers (Fig. S1†).

It can be noted that the  $E_{\text{ads}}$  of \*H, \*COOH and \*OOCH intermediates absorbed on pristine  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers are above zero as shown in Fig. 2, indicating unfavorable adsorption. In contrary, the adsorption of \*COOH and \*OOCH intermediates on the surface of TM/ $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers are strengthened, especially the \*OOCH adsorption, which reveals that the first protonation step tends to form \*COOH and \*OOCH intermediates for the CRR. In addition, the adsorption of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}$ , and  $\text{HCOOH}$  molecules on the surface of  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers was calculated to evaluate the interaction between these small molecules and the monolayers. As shown in Fig. S2 and Table S1,† the distinct difference in adsorption energies among  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}$ , and  $\text{HCOOH}$  due to the presence of active site on  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers, indicating the selectivity of CRR.

### 3.2 Selectivity between CRR and HER

As mentioned above, there is a competition to form \*COOH, \*OOCH and \*H intermediates in the first protonation step for CRR. In addition, it is reported that the reaction with lower free energy is assumed to be more selective with a low reaction barrier.<sup>48–51</sup> Therefore, the Gibbs free energies of \*COOH, \*OOCH and \*H absorbed on  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers were calculated and compared (shown in Fig. 3)

Fig. 2 The adsorption energy ( $E_{\text{ads}}$ ) of key intermediates (\*H, \*COOH and \*OOCH) adsorption on the surface of (a)  $\text{SnS}_2$  and (b)  $\text{SnSe}_2$  monolayers.

Fig. 3 The free energy change of the first protonation step in the CRR and HER on the surface of (a)  $\text{SnS}_2$  and (b)  $\text{SnSe}_2$  monolayers.

to gain an insight into the selectivity of the catalysts for CRR and HER, respectively. As shown in Fig. 3, the Gibbs free energy change of \*COOH and \*OOCH ( $\Delta G_{\text{*COOH}}$  and  $\Delta G_{\text{*OOCH}}$ ) versus that of \*H ( $\Delta G_{\text{*H}}$ ) was plotted, and usually the electrocatalysts under the dotted line are CRR selective, while above the dotted line are HER selective. For all TM/ $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers, \*OOCH is more favorable than \*COOH and they are below the diagonal line, implying that TM/ $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers prefer to form \*OOCH in the first protonation step for CRR rather than \*COOH and \*H, and leading to the inhibition of HER. However, pristine  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers are above the diagonal line, meaning more selective for HER. And the free energy barriers of the formation of \*COOH and \*OOCH for pristine  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers are higher than 1 eV, revealing that the CRR is difficult. In contrary, the free energy barriers of \*OOCH and \*COOH are obvious decreased for TM/ $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers, especially the free energy of \*OOCH is 0.04 eV, which exhibits that TM atoms (Fe, Co and Ni) anchored on the surface of  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers is an effective strategy to improve the catalytic activity for CRR.

### 3.3 Electrocatalytic activity

In order to gain a clearer understanding of the electrocatalytic performance and mechanism of TM/ $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers for  $\text{CO}_2$  reduction to  $\text{HCOOH}$ , the Gibbs free energies of all possible intermediates for CRR were systematically calculated and the corresponding configurations presented in Fig. S3 and S4.† The possible reaction pathways of CRR with two

Fig. 4 Schematic illustration of  $\text{CO}_2$  reduction to  $\text{HCOOH}$  and  $\text{CO}$  products on the surface of  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers. The gray, red and white atoms represent C, O and H, respectively.

Fig. 5 Free energy diagram for electroreduction of CO<sub>2</sub> to HCOOH (green), CO (red) and H<sub>2</sub> (blue) on the surface of (a) Fe/SnS<sub>2</sub>, (b) Co/SnS<sub>2</sub> and (c) Ni/SnS<sub>2</sub> monolayers.

electrons transfers are illustrated in Fig. 4, which have been widely accepted for the tin-based electrocatalysts.<sup>8,9,21–25</sup> And the lower free energy of \*OOCH intermediate on the surface of TM/SnX<sub>2</sub> (X = S and Se) monolayers also verifies the electroreduction of CO<sub>2</sub> to HCOOH prefers to proceed along CO<sub>2</sub> → \*OOCH → \*HCOOH → HCOOH (Fig. 5 and 6). However, there are high free energy barrier of \*COOH for CO<sub>2</sub> reduction to HCOOH and CO over the pristine SnX<sub>2</sub> (X = S and Se) monolayers (as shown in Fig. S5†), indicating the unfavorable electrocatalytic performance for CRR.

As shown in Fig. 5 and 6, the calculated energy barrier of \*OOCH is lower than those of \*H and \*COOH, revealing the selectivity of TM/SnX<sub>2</sub> (X = S and Se) monolayers for CO<sub>2</sub> electroreduction to HCOOH. It can be noted that Fe, Co and Ni atoms anchored on the surface of SnX<sub>2</sub> (X = S and Se) monolayers for CRR favor to form \*OOCH intermediate with a much smaller free energies compared to form \*COOH and \*H intermediates in the first protonation step. For the second protonation step, the reaction proceeds from \*OOCH to \*HCOOH for Ni/SnX<sub>2</sub> (X = S and Se) monolayers is exothermic, indicating a spontaneous process. In contrast, this protonation process for other monolayers is endothermic, which reveal that this step cannot spontaneously occur. Interestingly, the activation energy was found to be 0.04 eV for CO<sub>2</sub> → \*OOCH on Co/SnS<sub>2</sub>, and the subsequent step of \*OOCH → \*HCOOH and \*HCOOH → HCOOH also owns small barrier of about 0.21 and 0.02 eV, respectively. However, the energy barrier of CO<sub>2</sub> to \*OOCH and \*COOH on the pristine SnX<sub>2</sub> (X = S and Se) monolayers is above 1.5 eV (Fig. S5†), which is not beneficial for the formation of

HCOOH. Moreover, the free energy of \*H for HER on TM/SnX<sub>2</sub> (X = S and Se) is much higher than that of \*OOCH for CRR, confirms the selectivity of CRR over HER. The Fig. S6 and S7† also exhibit that Fe, Co and Ni atoms anchored on the surface of SnX<sub>2</sub> (X = S and Se) monolayers can obviously narrow the free energy barrier of the first protonation step (\* + CO<sub>2</sub> + H<sup>+</sup> + e<sup>-</sup> → \*OOCH) in CRR, which is beneficial to improve the electrocatalytic activity for CO<sub>2</sub> reduction to HCOOH. Meanwhile, Our calculated results also show that the free energy barrier (from \*CO + H<sup>+</sup> + e<sup>-</sup> to \*CHO) is high in this protonation step during CRR for TM/SnX<sub>2</sub> (X = S and Se) monolayers (shown in Fig. S8†), indicating unfavorable formation of formaldehyde and methanol product.

### 3.4 Limiting potential and product selectivity

It has been reported that the limiting potential difference (*i.e.*,  $U_L(\text{CO}_2) - U_L(\text{H}_2)$ , where  $U_L = -\Delta G_{\text{max}}/e$ ) can be used as a reasonable selectivity descriptor for CRR and HER.<sup>52–54</sup> Usually, the more positive  $U_L(\text{CO}_2) - U_L(\text{H}_2)$  value corresponds to the more favorable CRR selectivity. Therefore, to further evaluate the CRR and HER selectivity on different SnX<sub>2</sub> (X = S and Se) monolayers, the limiting potential difference ( $\Delta U_L$ ) at zero applied potential and acidic condition was calculated and compared. As clearly seen in Fig. 7, the  $\Delta U_L$  for CO<sub>2</sub> to HCOOH is positive on the surface of SnX<sub>2</sub> (X = S and Se) monolayers supported Co and Ni atoms, signifying a higher HCOOH selectivity for CRR. In contrast, the pristine SnX<sub>2</sub> (X = S and Se) monolayers exhibit worse CRR selectivity without applied potential ( $U = 0.0$  V *versus* RHE). As the Fe atom anchored on

Fig. 6 Free energy diagram for electroreduction of CO<sub>2</sub> to HCOOH (green), CO (red) and H<sub>2</sub> (blue) on the surface of (a) Fe/SnSe<sub>2</sub>, (b) Co/SnSe<sub>2</sub> and (c) Ni/SnSe<sub>2</sub> monolayers.

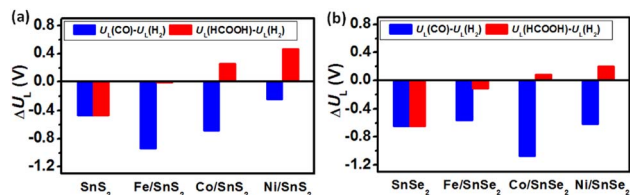

Fig. 7 Limiting potential differences ( $U_L(\text{CO}) - U_L(\text{H}_2)$  and  $U_L(\text{HCOOH}) - U_L(\text{H}_2)$ ) between CRR and HER on the surface of different (a)  $\text{SnS}_2$  and (b)  $\text{SnSe}_2$  monolayers at 0 V vs. RHE.

**Table 1** The potential determining steps (PDS), limiting potentials ( $U_L = -\Delta G_{\text{max}}/e$ ) and overpotentials ( $\eta = U_{\text{equ}} - U_L$ ,  $U_{\text{equ}}$  is the equilibrium potential) for  $\text{CO}_2$  reduction to HCOOH on the different surface of  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers

Surface	PDS	$U_L/\text{V}$	$\eta/\text{V}$
Pristine $\text{SnS}_2$	$^*\text{CO}_2 \rightarrow ^*\text{COOH}$	-1.39	1.19
Fe/ $\text{SnS}_2$	$^*\text{COOH} \rightarrow ^*\text{HCOOH}$	-0.32	0.12
Co/ $\text{SnS}_2$	$^+\text{CO}_2 \rightarrow ^*\text{CO}_2$	-0.23	0.03
Ni/ $\text{SnS}_2$	$^+\text{CO}_2 \rightarrow ^*\text{CO}_2$	-0.33	0.13
Pristine $\text{SnSe}_2$	$^*\text{CO}_2 \rightarrow ^*\text{COOH}$	-1.24	1.04
Fe/ $\text{SnSe}_2$	$^+\text{CO}_2 \rightarrow ^*\text{CO}_2$	-0.59	0.39
Co/ $\text{SnSe}_2$	$^*\text{OOCH} \rightarrow ^*\text{HCOOH}$	-0.21	0.01
Ni/ $\text{SnSe}_2$	$^+\text{CO}_2 \rightarrow ^*\text{CO}_2$	-0.25	0.05

$\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ), the  $\Delta U_L$  for HCOOH route becomes nearly zero, suggesting the obvious effect of suppressing HER. In addition, the calculated limiting potential difference of  $U_L(\text{CO}) - U_L(\text{H}_2)$  is negative for all  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers, which indicates worse CRR selectivity for CO production.

The potential determining steps (PDS), limiting potentials ( $U_L$ ) and overpotentials ( $\eta$ ) for  $\text{CO}_2$  reduction to HCOOH and CO were summarized in Tables 1 and S2,<sup>†</sup> respectively. It can be noted that the free energy changes of PDS for pristine  $\text{SnS}_2$  and  $\text{SnSe}_2$  are obvious higher than those of TM/ $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ), and the high overpotentials for  $\text{CO}_2$  reduction to HCOOH and CO reveal poor CRR selectivity. In contrast, the electrocatalytic activity of  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers supported Fe, Co and Ni atoms for  $\text{CO}_2$  to HCOOH production is distinctly enhanced with lower overpotentials, but for CO formation displaying inferior catalytic activity. Especially, the Ni/ $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers are supposed to be superior in catalyzing  $\text{CO}_2$  to HCOOH based on  $U_L$  and  $\eta$  calculated from free energy changes of PDS, where  $^+\text{CO}_2 \rightarrow ^*\text{CO}_2$  is predicted to be the PDS. All these results illustrate that the adsorption of Fe, Co and Ni atoms on the surface of  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers can effectively tune the catalytic activity for CRR, which would provide an insight to the selective electroreduction of  $\text{CO}_2$  based on the materials in the future experiment.

## 4. Conclusions

In summary, the electrocatalytic activity of pristine and TM atoms (Fe, Co and Ni) anchored on  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ )

monolayers for  $\text{CO}_2$  reduction to HCOOH were systematically investigated by first-principles calculation method. The calculated free energies of  $^*\text{COOH}$ ,  $^*\text{OOCH}$  and  $^*\text{H}$  reveal that it is easier to form  $^*\text{OOCH}$  intermediate in the first protonation step of CRR on the  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers supported Fe, Co and Ni atoms. Meanwhile, the electrocatalytic activity of  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers for  $\text{CO}_2$  reduction to HCOOH can be obviously promoted by TM atoms (Fe, Co and Ni) adsorption, which confirms the selectivity of CRR over HER. Moreover, the calculated limiting potential differences ( $\Delta U_L$ ) display that the adsorption of Co and Ni on  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers prefers a higher HCOOH selectivity for CRR with lower overpotentials, while pristine  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers exhibit worse CRR selectivity with higher overpotentials both for HCOOH and CO production. All these results demonstrate that TM atoms (Fe, Co and Ni) own great potential of enhancing the electrocatalytic performance of  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ ) monolayers for  $\text{CO}_2$  reduction to HCOOH, which can provide a theoretical reference for designing high-efficiency  $\text{SnX}_2$  ( $X = \text{S}$  and  $\text{Se}$ )-based single atom catalysts experimentally in future.
