Visible-light-mediated synthesis of oxime esters *via* multicomponent reactions of aldehydes, aryl amines, and *N*-hydroxyphthalimide esters†

Anh Thu Nguyen^a and Hee-Kwon Kim  ^{*ab}

Oxime esters are useful scaffolds in many organic chemistry transformations. Herein, a novel visible-light-mediated three-component reaction for synthesis of oxime esters is reported. Aldehydes, aniline, and *N*-hydroxyphthalimide (NHPI) esters were used as substrates in this three-component reaction, and eosin Y was used as a crucial photocatalyst for the reaction. Wide ranges of aldehydes and NHPI esters were well tolerated in this reaction method, generating various oxime esters with high efficiency under mild reaction conditions. This visible-light-mediated methodology will be a promising approach to synthesize useful oxime esters in a single step.

Introduction

Oxime esters have been found in various areas. For example, a wide range of biologically active compounds with anticancer,¹ anti-inflammatory,² antifungal,³ antioxidant and antimicrobial⁴ activities contain oxime ester moieties. Additionally, oxime esters are an important scaffold for many organic synthesis processes such as C–C bond cleavage,⁵ cyanoalkylation,⁶ hydroesterification,⁷ cross coupling,⁸ sulfonylation,⁹ and cyclization.¹⁰ Recently, oxime esters were used as photo-initiators in photoreactions for various transformations.¹¹ Due to their utility, several methods have been reported for the synthesis of oxime esters (Scheme 1). Oxime esters can be prepared using two-step procedures: the formation of aldoximes and ketoximes *via* reactions of aldehydes or ketones with NH₂OH, followed by esterification of oximes with carboxylic acids,¹² aldehydes,¹³ or esters.¹⁴

Light has been employed for numerous chemical transformations.¹⁵ Photochemical reactions are initiated by the absorption of light as the source of energy, and they have become useful methods with many applications in organic chemistry and materials.¹⁶ Additionally, photochemical reactions are usually carried out at room temperature and can tolerate a wide range of transformations.¹⁷

N-Hydroxyphthalimide (NHPI) esters also are useful substrates in a variety of reactions because they can be prepared

with ease and at low cost from carboxylic acids and *N*-hydroxyphthalimides. NHPI esters have been used in many reactions for the formation of C–C bonds.¹⁸ Reactions of NHPI esters to generate C–B and C–Si bonds have been developed.¹⁹ Various photoredox reactions employing NHPI esters also have been reported. These reactions included formation of C–C bonds such as alkylation of heterocycles²⁰ and alkenylation,²¹ formation of C–O and C–S bonds,²² and remote C–H oxidation.²³ Additionally, NHPI esters were successfully employed in annulation reactions under visible-light irradiation to produce saturated heterocycles.²⁴

We were interested in developing practical and useful synthetic methods for oxime ester compounds. Specifically, utilization of a visible-light-mediated reaction to yield oxime esters can be a promising strategy. Herein, we describe a visible-light-induced one-pot reaction *via* three-component reaction of aldehyde, aniline, and NHPI esters for the preparation of oxime ester compounds (Scheme 1).

Previous strategies:

Results and discussion

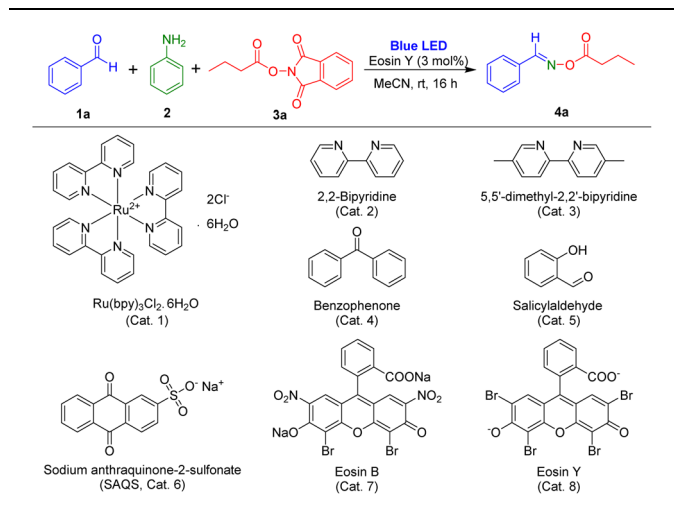

One-pot reactions are useful approaches to produce organic compounds with many advantages including minimal waste and reduced cost and effort.²⁵ Thus, we tried to use multicomponent reactions for the preparation of oxime esters. For the present study, we assumed that reaction of aldehydes with amines could also produce the radical acceptors imines, and, under irradiation by visible light, NHPI esters could be converted into carboxylic radicals. Then, target oxime esters could be formed through reaction between imines and carboxylic radicals.

To assess our idea, novel visible-light-induced multicomponent reactions using aldehydes, aryl amine, and NHPI ester in the presence of a photocatalyst were examined. In the initial experiments, benzaldehyde, aniline, and 1,3-dioxoisindolin-2-yl butyrate (NHPI ester of butyric acid) were selected as the model substrates, and eosin Y was employed as a photocatalyst for optimization of the reaction condition (Table 1) because eosin Y has been used for visible-light induced reactions.²⁶ The reaction using eosin Y in MeCN was conducted under irradiation of blue LEDs at room temperature. Under standard conditions, (*E*)-benzaldehyde *O*-butyryl oxime, the target product, was obtained in 92% yield in 16 hours (Table 1, entry 1). The other photocatalysts were tested (Table 1, entries 2–8). The reaction using Ru(bpy)₃Cl₂·6H₂O did not produce the desired product (Table 1, entry 2), and the use of 2,2-bipyridine or benzophenone resulted in preparation of the target product in less than 30% yield (Table 1, entries 3 and 4). Photocatalysts 5,5-dimethyl-2,2'-bipyridine, salicylaldehyde, sodium anthraquinone-2-sulfonate (SAQS), and eosin B afforded the corresponding products in yields ranging from 64% to 90% (Table 1, entries 5–8).

Several solvents including CH₂Cl₂, DCE, and toluene were also tested in photoreactions, but the reactions in these solvents produced oxime ester in less than 20% yield (Table 1, entries 9–11). Other solvents of THF, DMF, 1,4-dioxane, and ethyl acetate provided improved reaction efficiencies (Table 1, entries 12–15). However, MeCN was the most suitable solvent for this multicomponent reaction. In addition, photoreactions using other nitrogen sources were also conducted. However, these reactions were not successful (Table 1, entries 16–18). Notably, using these basic aliphatic amines led to the hydrolysis of NHPI ester substrates and benzaldehyde substrate remained unreacted, indicating the vital role of aniline in the reaction. The influences of catalyst and light on the reaction were examined. The desired product was not prepared and only imine intermediate was generated in the reaction in the absence of photocatalyst (Table 1, entries 19 and 21). Reaction in the absence of light was performed, and less than 15% of product was obtained (Table 1, entry 20).

Next, several different light types were tested to examine their influence on the reaction (Table S1†). Irradiation with white LEDs, green LEDs, and compact fluorescent lights (CFLs) led to generation of products with yields of 71%, 87%, and 88%, respectively. However, no other additional improvements of

^a Reaction conditions: aldehyde **1a** (1.0 mmol), aniline **2** (1.0 mmol), *N*-hydroxyphthalimide ester (NHPI ester) **3a** (1.2 mmol), photocatalyst (0.03 mmol), solvent (2 mL), room temperature, blue LEDs (5 W × 2 bulbs), 16 h. ^b Isolated yield after purification by flash column chromatography. ^c No reaction.

reaction were observed compared to the reaction using blue LEDs. Different amounts of photocatalyst were investigated to determine optimal reaction conditions (Table S2†). Use of 1 mol% of eosin Y as a catalyst yielded the desired oxime ester in 76% yield, and a reaction using 3 mol% of eosin Y boosted the yield to 92%. However, greater than 3 mol% of eosin Y did not show an additional increase. Amounts of 1,3-dioxoisindolin-2-yl butyrate in the reaction were also examined, and reaction using 1.2 equiv. of 1,3-dioxoisindolin-2-yl butyrate afforded the target product in high yield (Table S3†).

Based on the optimized conditions, we explored the scope of the visible-light-induced reaction. First, various aldehydes were

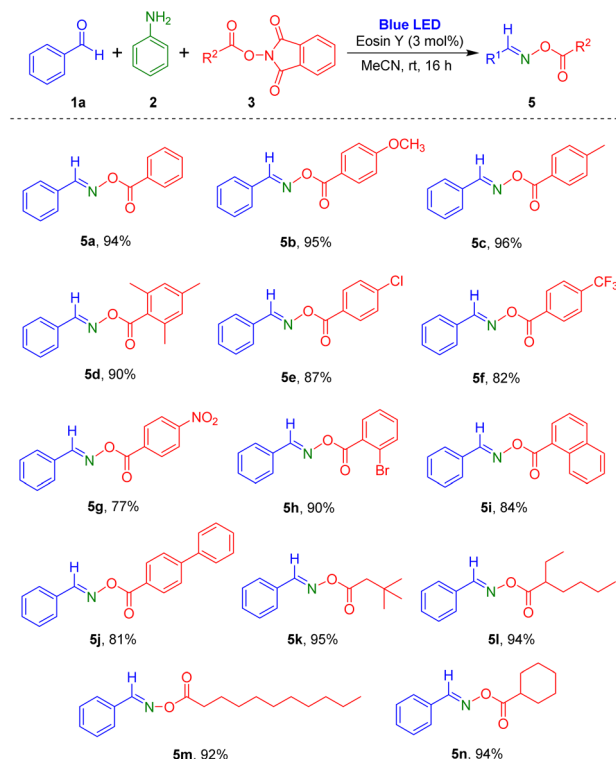

Scheme 2 Substrate scope of aldehydes. ^aReaction conditions: aldehyde **1** (1.0 mmol), aniline **2** (1.0 mmol), *N*-hydroxyphthalimide ester (NHPI ester) **3a** (1.2 mmol), eosin Y (0.03 mmol), MeCN (2 mL), blue LEDs (5 W × 2 bulbs), 16 h. ^bIsolated yield after purification by flash column chromatography.

reacted with aniline and 1,3-dioxoisindolin-2-yl butyrate (Scheme 2). Aryl aldehydes containing electron-donating (methyl) or electron-withdrawing substituents (chloro and nitro) in the *para*-position on the phenyl ring produced the desired products **4a–4d** in high yields (89–93%). Reaction of aryl aldehydes with electron-donating or electron-withdrawing groups at the *ortho*-position of the aromatic ring also yielded the corresponding products **4e–4g** at 83–91%. Notably, reaction of heterocyclic aromatic substrates 2-pyridinecarboxaldehyde and 2-thiophenecarboxaldehyde provided the target oxime esters (**4i** and **4j**) in yields of 89% and 84%, respectively. Additionally, several alkyl aldehydes were tested for this reaction protocol, and they were tolerated in the reaction to afford the target oxime esters (**4k–4n**) in high yields.

Subsequently, reactions of a variety of NHPI esters with benzaldehyde and aniline were carried out (Scheme 3). Aromatic carboxylic acid-derived NHPI esters with electron-donating (methyl and methoxy) or electron-withdrawing substituents (chloro, bromo, trifluoromethyl, and nitro) readily produced the desired oxime esters (**5a–5h**). Particularly, reaction of NHPI ester of 2,4,6-trimethylbenzoic acid, which has steric hindrance, gave the target product **5d** in 90% yield. Using the process, NHPI esters of the two aromatic carboxylic acids 1-naphthoic acid and biphenyl-4-carboxylic acid were also transformed to the corresponding oxime ester products (**5i** and **5j**). Additionally, various alkyl carboxylic acid derived NHPI esters were employed in the reaction, and they were tolerated in this reaction method to give the desired products (**5k–5n**) in high

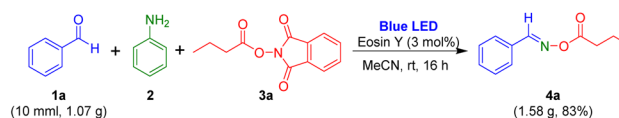

Scheme 3 Substrate scope of NHPI esters. ^aReaction conditions: aldehyde **1a** (1.0 mmol), aniline **2** (1.0 mmol), *N*-hydroxyphthalimide ester (NHPI ester) **3** (1.2 mmol), eosin Y (0.03 mmol), MeCN (2 mL), blue LEDs (5 W × 2 bulbs), 16 h. ^bIsolated yield after purification by flash column chromatography.

yields. Notably, the reaction of NHPI esters prepared from undecanoic acid, which contains a long carbon chain, generated the target oxime ester compound **5m** in 92% yield.

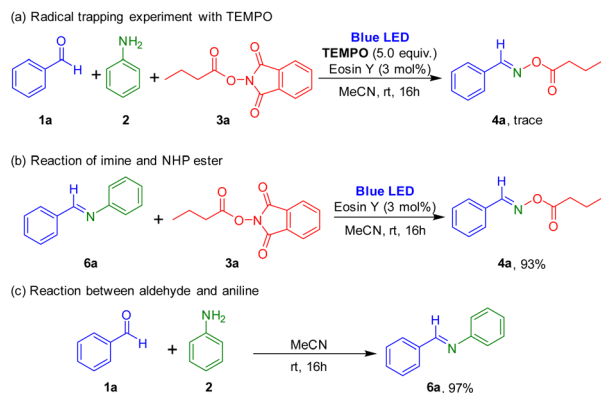

Next, gram-scale synthesis of oxime esters from aldehyde, aniline, and 1,3-dioxoisindolin-2-yl butyrate was performed to evaluate the visible-light-mediated multi-component reaction (Scheme 4). Benzaldehyde **1a** (10.0 mmol, 1.07 g) readily reacted with aniline and 1,3-dioxoisindolin-2-yl butyrate to generate the target oxime ester **4a** in 83% yield.

Several control experiments were carried out to understand the reaction mechanism (Scheme 5). When 5.0 equiv. of TEMPO (2,2,6,6-tetramethyl-1-piperidinyloxy), a radical scavenger, was added to this reaction, formation of the target oxime ester was prevented, which suggested that the synthesis used a radical pathway. Reaction of imine and 1,3-dioxoisindolin-2-yl butyrate in the presence of photocatalyst was performed under the irradiation of blue LEDs, and the target product was successfully obtained. Also, the reaction between aldehyde and aniline readily afforded the imine.

Scheme 4 Gram-scale reaction of three components substrate scope of aldehydes.

Scheme 5 Control experiments.

Moreover, light on/off experiments were conducted to assess the effect of visible light on this synthesis (Fig. 1). Synthesis of oxime ester was remarkably slow in the dark, while irradiation by blue LEDs readily generated the desired product **4a** from starting substrates. This suggests that irradiation of visible light played a crucial role in this reaction.

We proposed a plausible catalytic cycle mechanism for this process (Scheme 6) based on the results of control experiments and previously published reports.²⁷ Photocatalyst eosin Y^{2-} forms eosin Y^{2-*} under irradiation of blue LEDs. NHP ester **3a** is transformed to radical anion **A** via reaction of eosin Y^{2-*} . Then, radical anion **A** yields carboxylic radical **B** by release of a phthalimide anion. Carboxylic radical **B** reacts with imine **C**, which is prepared by treatment of aldehyde **1a** and amine **2**, to give C-centered radical intermediate **D**. Intermediate **D** provides the imine-like cation **E** via single electron transfer with eosin Y^{2-} while photocatalyst eosin Y^{2-} is recovered to close the catalytic cycle. The desired product **4a** is finally produced by the elimination of the phenyl group with phthalimide anion.

Experimental

General procedure of the synthesis of oxime esters (**4a–4n**, **5a–5n**)

Benzaldehyde **1a** (0.106 g, 1.0 mmol, 1.0 equiv.), aniline **2** (0.093 g, 1.0 mmol), 1,3-dioxoisindolin-2-yl butyrate (NHP ester) **3a** (0.233 g, 1.2 mmol), and eosin Y (0.021 g, 0.03 mmol) were added to acetonitrile (2 mL). The reaction mixture was

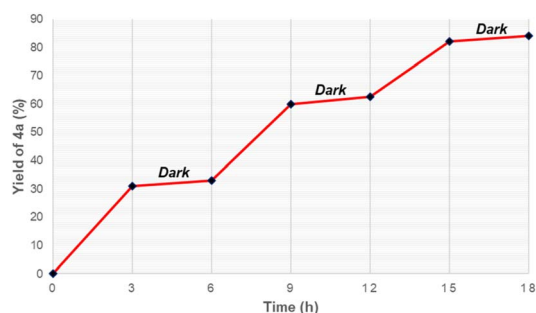

Fig. 1 Light on/off experiments.

Scheme 6 A plausible mechanism.

stirred under irradiation of 5 W blue LEDs ($\times 2$) at room temperature for 16 hours. The reaction product was extracted with EtOAc (50 mL) and washed with aqueous NaHCO_3 (50 mL), followed by water (50 mL). The organic layer was dried with anhydrous sodium sulfate and was concentrated under reduced pressure. The residue was purified by flash column chromatography on silica gel eluting with hexane–EtOAc as eluent to afford the target product (**4a**) as a yellow oil (0.175 g, 92%).

Conclusions

In summary, efficient visible-light-mediated method for the preparation of oxime esters through one-pot multicomponent reaction employing aldehydes, aniline, and NHP esters was described. Eosin Y was used as a suitable photocatalyst for the synthesis of oxime esters. A wide range of oxime esters bearing aliphatic and aromatic groups was successfully obtained by novel visible-light-mediated reaction under mild conditions. The method has advantages such as use of a wide scope of substrates, simple operation, and mild reaction conditions. Thus, this method allows easy and effective preparation of oxime esters in one step.
