# Synthetic routes to trifluoromethylphenyl diazirine photolabeling reagents containing an alkyne substituent (TPDYNE) for chemical biology applications†

Mingxing Qian,<sup>a</sup> Yuanjian Xu<sup>a</sup> and Douglas F. Covey  <sup>abcd</sup>

The trifluoromethylphenyl diazirine (TPD) group is widely used in photoaffinity labeling studies. The TPDYNE group (TPD with an additional alkyne substituent on the phenyl ring) enables the use of click chemistry in conjunction with photoaffinity labeling and expands the utility of the TPD group. New methods for preparing previously known as well as new TPDYNE reagents are reported. Additional methods for preparation of a TPDYNE precursor from which the TPDYNE group can be generated once the precursor is attached to the molecule of interest are also described. Procedures for attaching the TPDYNE or TPDYNE precursor to carboxyl, amino, hydroxyl and alkyne groups are demonstrated using steroids as examples.

The trifluoromethylphenyl diazirine (TPD) group is a widely used photoaffinity labeling (PAL) group for chemical biology applications.<sup>1,2</sup> We previously incorporated the TPD group into analogues of both neurosteroid and cholesterol analogues for photolabeling studies.<sup>3,4</sup> In cases where we wanted to have the option to use click chemistry in conjunction with photolabeling we incorporated an alkyne group into the steroid portion of the analogues.<sup>4</sup> This strategy entails finding a location for the alkyne in the steroid that does not negate biological activity and can require lengthy steroid synthesis. Realizing that placing the alkyne group on the TPD moiety would obviate the development of chemical methods for modifying the steroid, we searched the literature for previous reports of alkyne modified TPD groups.

Two alkyne modified TPD precedents were found in the literature. The first modification involved the initial preparation of the difluoro alkyne **1** (Fig. 1) and its subsequent attachment to an aromatic ring to ultimately produce compound **2**.<sup>5</sup> Although we were able to efficiently attach difluoro alkyne **1** to *t*-butyl(4-iodobenzyl)dimethylsilane to obtain 1-(4-((*tert*-butyldimethylsilyl)methyl)phenyl)-2,2-

difluorobut-3-yn-1-one, the conversion of the ketone group to the diazirine group was not successful. Consequently, we turned our attention to the second reported modification of a TPD group which involves placing the alkyne group on the aromatic ring of the TPD group (**3a**, **3b**).<sup>6</sup> As reported, compound **3b** was incorporated into a dantrolene analogue and shown to photolabel proteins involved in physiological Ca<sup>2+</sup> release from sarcoplasmic reticulum of skeletal muscle and compound **3b** was incorporated into a nucleoside analogue to photolabel microRNA targets.<sup>6,7</sup> Both of these prior studies demonstrate that alkyne modified TPD groups (hereafter referred to as TPDYNE groups) are effective PAL groups.

Use of the TPDYNE group in PAL studies has been limited to the studies cited and general methods for attachment of the TPDYNE group to different functional groups have not been reported. Using a newly developed synthetic route we prepared the previously reported compounds **3a** and **3b** as well as the new alkyne TPDYNEs **3c–3e**. We also developed a synthetic route to TPDYNE precursors from which the TPDYNE can be generated once the precursor is attached to the probe of interest. The precursors are useful when the TPDYNE group cannot be efficiently attached to the probe of interest. General methods for the attachment of these PAL groups to carboxylic acid, amine, hydroxyl and alkyne groups are described using steroids as examples.

TPDYNEs **3a–3e** were prepared from 3,5-dibromobenzoic acid methyl ester **4** as detailed in Fig. 2. Reduction of ester **4** with DIBAL-H gave alcohol **5** (93% crude) and subsequent protection of the hydroxyl group with the TBS group gave silyl ether **6** (~100%). Treatment of compound **6** with 1.05 equivalents of *n*-BuLi and paraformaldehyde gave alcohol **7** (46%) and the newly formed hydroxyl group was protected as the MOM ether **8** (90%). The remaining bromo substituent in compound **8** was replaced by a trifluoromethyl ketone group using *n*-BuLi and 1-trifluoroacetyl piperidine yielding compound **9** (82%). Trifluoromethyl ketone **9** was converted into the oxime **10** (64%), tosylated to give compound **11** (85%) and then transformed into the trifluoromethyl diazirine **12** in the standard manner (liquid NH<sub>3</sub> followed by Et<sub>3</sub>N, I<sub>2</sub>; 88%). After removal of the TBS group using TBAF (94%), trifluoromethyl diazirine **13** was converted by MnO<sub>2</sub> oxidation followed by a Bestmann–Ohira reaction to TPDYNE **14** (80% for the two steps). Removal of the MOM protecting group using HCl generated *in situ* from acetyl chloride in MeOH yielded TPDYNE **3a** (88%). Treatment of compound **3a** with CBr<sub>4</sub>/PPh<sub>3</sub> converted it to TPDYNE **3b** (~100%). Treatment of compound **3a** with I<sub>2</sub>, PPh<sub>3</sub> and imidazole gave TPDYNE **3c** (74%). Reaction of compound **3c** with NaN<sub>3</sub> produced TPDYNE **3d** (78%) and reduction of TPDYNE **3d** with PPh<sub>3</sub> yielded TPDYNE **3e** (50%).

As described below, we found that TPDYNE **3b** or **3c**, unlike the analogous TPD compounds, could not be attached in an ether linkage to a hydroxyl group in an acceptable yield. To overcome this difficulty a synthetic route to a TPDYNE precursor from which the TPDYNE group could be formed after the precursor is attached to a hydroxyl group was developed. Fig. 3 shows the synthetic route for the TPDYNE precursor **17** and it was obtained using a different method from the one shown for its preparation in Fig. 2. This alternate method for obtaining compound **7** does not require the use of *n*-BuLi when the method is carried out on a large scale. Accordingly, dimethyl 5-bromoisophthalate **15** was reduced to diol **16** using DIBAL-H (93%). Using 1 equivalent of TBSCl, the mono silylated alcohol **7** was obtained in 36% yield. Both unreacted diol **16** and the disilylated diol also formed in the reaction can be recycled if desired to obtain additional alcohol **7**. Compound **7** was converted to compound **8** (90%) and then converted to compound **13** as described in Fig. 2. Compound **13** was reacted with PPh<sub>3</sub>

and I<sub>2</sub> to give iodinated TPDYNE precursor **17** (73%). Iodide **17** was converted into azide **18** using NaN<sub>3</sub> (90%) for use as described later.

Reaction conditions for attachment of the TPDYNE group to compounds with an amino or carboxyl were established using steroids containing these substituents at the 17β-position (Fig. 4). Using LiOH in DMF, aminosteroid **19** was reacted with TPDYNE **3c** to give steroid **20** (56%) and the MOM ether was

removed using HCl in MeOH to obtain steroid **21** (47%). Steroid carboxylic acid **22** was coupled to TPDYNE **3a** in an ester linkage using *N,N'*-dicyclohexylcarbodiimide to give steroid **23** (92%). Steroid **22** was coupled to TPDYNE **3e** in an amide linkage by first reacting the steroid with *N*-hydroxysuccinimide and *N,N'*-dicyclohexylcarbodiimide to give the intermediate *N*-succinimidyl ester (88%) and then reacting this intermediate with TPDYNE **3e** in DMF to give steroid **24** (52%).

As noted above, TPDYNE **3c** could not be attached to a steroid 17β-hydroxyl group in an ether linkage in yields of more than ~5%. Attempted reaction conditions included treating steroid **25** with either NaH or KH in THF at room temperature for 1 h followed by the addition of either **3b** or **3c** and then reflux for 16 h or continuing the reaction at room temperature for 16 h. Consequently, we used the TPDYNE precursor **17** to obtain a hydroxyl group modified with a TPDYNE group in an ether linkage (Fig. 5). Using KH in THF, TPDYNE precursor **17** was reacted with steroid **25** to give steroid **26** (90%). Removal of both MOM protecting groups from steroid **26** using HCl in MeOH gave steroid **27** (~100%). Oxidation of steroid **27** with MnO<sub>2</sub> gave steroid **28** which was immediately reacted with Bestmann–Ohira reagent to give steroid **29** (48% from steroid **27**).

In some circumstances where the nucleophilic groups in the molecule of interest cannot be used to attach a photo-labeling group without losing activity a strategy is needed whereby the TPDYNE group can be attached by means other

than a nucleophilic addition reaction. One such strategy if the molecule of interest contains an alkyne group would be to attach a TPDYNE azide containing reagent to it in a click reaction. TPDYNE **3d**, which was prepared only as an intermediate to prepare TPDYNE **3e**, could possibly be used for this purpose. However, reaction of compound **3e** with itself in the click reaction would likely lead to a poor yield of the desired click reaction with the molecule of interest. To avoid this problem the TPDYNE precursor **18** (Fig. 3) can be used in a click reaction and the TPDYNE group can be formed subsequently using the same sequence (27 to 29) described in Fig. 5. Thus, TPDYNE precursor **18** was attached to steroid **30** in a click reaction (Fig. 6) to form steroid **31** (50%). The MOM group was removed using HCl in MeOH to give steroid **32** (76%). Oxidation of steroid **32** with MnO<sub>2</sub> gave aldehyde **33** (52%) and the TPDYNE modified steroid **34** was formed from the aldehyde using the Bestmann–Ohira reagent (50%).

In conclusion, we report new synthetic methods for the preparation of a group of TPDYNE reagents. Additionally, we report reaction conditions for the attachment these reagents to hydroxyl, amino and carboxylic acid and alkyne groups using steroids as examples. We believe the methods reported will lead to an increased use of the TPDYNE group in chemical biology applications.
