## Introduction

Metal-ligand bonding is crucial to transition metal chemistry. The nature and strength of bonding between the metal and ligand determine the stability, geometry and reactivity of intermediates in catalytic reactions.<sup>1</sup> Thus, understanding the nature of the metal-ligand bond is very important.<sup>2,3</sup> Nitrogen trifluoride ( $\text{NF}_3$ ) is a stable and long known compound and was first synthesized by Otto Ruff and co-workers *via* the electrolysis of a  $\text{HF}/\text{NH}_4\text{F}$  mixture in 1928.<sup>4</sup> Although it has been widely used as a reactant in gas-phase reactions<sup>5</sup> and synthetic chemistry,<sup>6</sup> the coordination chemistry of this molecule as a Lewis base has received less attention, which is most likely due to its weak Lewis base character. Nevertheless, the proton affinity of  $\text{NF}_3$  has been experimentally measured many times since 1980.<sup>7</sup> Experimental and theoretical investigation on the complexes of  $\text{NF}_3$  with Lewis acids, such as  $\text{BH}_{3-n}\text{F}_n$  ( $n = 0-3$ )<sup>8</sup> and  $\text{AlH}_3$  (ref. 9), indicated that nitrogen trifluoride can act as a nitrogen donor to form  $\text{H}_3\text{B}-\text{NF}_3$ ,  $\text{F}_3\text{B}-\text{NF}_3$  and  $\text{H}_3\text{Al}-\text{NF}_3$  adducts. Nitrogen trifluoride complexes of coinage metals Cu, Ag and Au supported by ligands such as cyanogen and halides were studied by density functional theory.<sup>10</sup> In addition, theoretical studies on the metal ligand back-bonding in  $\text{Pd}(\text{NF}_3)$  and  $\text{LPd}(\text{NF}_3)$  ( $\text{L} = \text{NH}_3$ ,  $\text{PH}_3$ , CO) complexes using NBO analysis demonstrated that the  $\text{NF}_3$  ligand also has a strong  $\pi$  acceptor character.<sup>11</sup> Besides the neutral complexes, some nitrogen trifluoride ion complexes have also been studied

computationally.<sup>12</sup> It was found that the  $\text{H}^+$ ,  $\text{Li}^+$ ,  $\text{Na}^+$  and  $\text{K}^+$  nitrogen trifluoride complexes appear to form ion-dipole interactions and the  $\text{Li}^+$ ,  $\text{Mg}^+$  and  $\text{Be}^+-\text{NF}_3$  cations could be detected as stable products in the gas phase.

Recently, reactions of group 4, 6, 8, 9, and 11 metals, Th, and U with nitrogen trifluoride in excess neon and argon have been studied, and difluoroamino, fluoronitrenoid and nitride metal complexes ( $\text{F}_2\text{NMF}$ ,  $\text{FNMF}_2$ , and  $\text{NMF}_3$ ) have been prepared and characterized by matrix-infrared spectroscopy and theoretical calculations.<sup>13-16</sup> In contrast to the nitrogen trifluoride reactions reported above, the analogue ammonia molecule reacted with metal atoms to form  $\text{M}(\text{NH}_3)$  complexes first, which rearranged to  $\text{HMNH}_2$  *via* N-H bond insertion upon light excitation.<sup>17</sup> The weak N-F bond, which is only about half as strong as the N-H bond in the  $\text{NH}_3$  molecule,<sup>18</sup> makes the insertion reaction easier than that for the N-H bond. This may result in the spontaneous formation of N-F bond insertion complexes. Moreover, fluorine is the most electronegative element, the lone pair electronic density in the nitrogen atom of  $\text{NF}_3$  is decreased, and the dipole moment direction is also reversed as compared with those of  $\text{NH}_3$ ,<sup>19</sup> both of which make it less favourable to give the  $\text{M}(\text{NF}_3)$  complex with a M-N interaction. To the best of our knowledge, there are no experimental reports on the nitrogen trifluoride metal coordination in which the  $\text{NF}_3$  ligand does not immediately react further. Here we report the preparation of the nitrogen trifluoride complexes of group 10 metals  $\text{M}(\text{NF}_3)$  ( $\text{M} = \text{Pd, Pt}$ ) from laser ablated metal atoms with  $\text{NF}_3$  molecules and their spectroscopic identification in low-temperature neon and argon matrices. The nitrogen-coordination complexes will further isomerize to the more stable insertion products  $\text{FNMF}_2$  upon blue LED ( $\lambda = 470$  nm) light irradiation.

## Results and discussion

The title complexes were produced by the reactions of laser-ablated palladium, platinum atoms and nitrogen trifluoride in solid argon, and were recorded by FTIR absorption spectroscopy with isotopic substitutions. The IR spectra in the 1150–550 cm<sup>−1</sup> region using a 0.5% NF<sub>3</sub>/Ar mixture are represented in Fig. 1 and 2. After 60 min of sample deposition, common absorption bands due to NF and NF<sub>2</sub> radicals are observed,<sup>20</sup> which decrease on annealing but slightly increase on blue LED ( $\lambda = 470$  nm) light irradiation. No obvious absorption bands of molecular metal fluorides are observed. Besides these common product absorption bands, new metal dependent absorption bands were also detected, which can be classified into two groups based on their identical annealing and photochemical behaviours (labeled **A** and **B** in Fig. 1 and **C** and **D** in Fig. 2). Since some absorption bands are partially overlapped by the nitrogen trifluoride absorption bands, a difference IR spectrum taken from the spectrum after blue LED ( $\lambda = 470$  nm) light irradiation minus the spectrum after 20 K annealing is obtained and represented in Fig. S1 and S2.<sup>†</sup> Similar experiments were also performed using an isotopically labelled compound <sup>15</sup>NF<sub>3</sub> and a <sup>14</sup>NF<sub>3</sub> + <sup>15</sup>NF<sub>3</sub> mixture. The IR spectra in the selected region are shown in Fig. S1 and S2.<sup>†</sup> All observed band positions are listed in Table 1.

Experiments were also carried out with laser-ablated palladium, platinum atoms and NF<sub>3</sub> in excess neon. The spectra with 0.1% NF<sub>3</sub> and isotopic substitutions in neon are shown in Fig. S3–S6.<sup>†</sup> The same products as detected in argon are presented, but the Pd(NF<sub>3</sub>) product absorption bands are weaker than those detected in solid argon. The product absorption bands in solid neon are given in Table 1. The band positions are blue-shifted to higher wave numbers compared to those of the argon matrix.

Fig. 1 Infrared spectra in the 1150–550 cm<sup>−1</sup> region from co-deposition of laser-ablated Pd atoms with 0.5% NF<sub>3</sub> in argon. (a) After 60 min of sample deposition, (b) after annealing to 15 K, (c) after annealing to 20 K, and (d) after 10 min of blue LED ( $\lambda = 470$  nm) light irradiation. A: Pd(NF<sub>3</sub>); B: FNPdF<sub>2</sub>.

Fig. 2 Infrared spectra in the 1150–550 cm<sup>−1</sup> region from co-deposition of laser-ablated Pt atoms with 0.5% NF<sub>3</sub> in argon. (a) After 60 min of sample deposition, (b) after annealing to 15 K, (c) after annealing to 20 K, and (d) after 10 min of blue LED ( $\lambda = 470$  nm) light irradiation. C: Pt(NF<sub>3</sub>); D: FNPtF<sub>2</sub>.

The absorption bands at 834.4 and 771.3 cm<sup>−1</sup> labeled **A** (Fig. 1, trace c) are assigned to the Nitrogen-coordination Pd(NF<sub>3</sub>) complex. These absorption bands appeared after sample annealing to 15 K and increase remarkably when the matrix samples are annealed to 20 K, but disappeared totally under 10 min blue LED ( $\lambda = 470$  nm) light irradiation. Both bands are red-shifted compared to the N–F stretching vibration (1028.1 and 898.1 cm<sup>−1</sup>) modes of free NF<sub>3</sub> in argon.<sup>15</sup> In the experiment using the isotopic-labeled <sup>15</sup>NF<sub>3</sub> sample, the absorption bands shift to 813.8 and 753.7 cm<sup>−1</sup> with a <sup>14/15</sup>N isotopic shift of 20.6 and 17.6 cm<sup>−1</sup> respectively. The band position and isotopic splitting in the mixed <sup>14</sup>NF<sub>3</sub> + <sup>15</sup>NF<sub>3</sub> (1 : 1) experiment (Fig. S1<sup>†</sup>) confirm that only one NF<sub>3</sub> ligand is involved. Accordingly, the two absorption bands 834.4 and 771.3 cm<sup>−1</sup> are assigned to the symmetric and antisymmetric N–F stretching modes. The Pd(NF<sub>3</sub>) complex in solid neon is observed at 838.6 and 778.1 cm<sup>−1</sup>, which are only 4.2 and 6.8 cm<sup>−1</sup> blue-shifted from those in argon, indicating a weak matrix effect. This type of 1 : 1 metal-ligand complex with a metal coordinated by a nitrogen atom of the ligand is common for molecular complexes.<sup>21</sup>

In addition to the Pd(NF<sub>3</sub>) absorption bands, another group of absorption bands at 965.6, 612.3 and 575.5 cm<sup>−1</sup> labeled **B** (Fig. 1, trace d) are produced after sample co-deposition. These absorption bands increased under blue LED ( $\lambda = 470$  nm) light irradiation at the expense of group **A** absorption bands, indicating that product **B** is a structural isomer of product **A**, and is assigned to the FNPdF<sub>2</sub> complex. The 965.6 cm<sup>−1</sup> absorption band is mainly a F–N stretching vibration with a large <sup>14/15</sup>N shift (19.9 cm<sup>−1</sup>). The <sup>14/15</sup>N shift is close to those of 21.4 cm<sup>−1</sup> in FNCOf<sub>2</sub> and 18.9 cm<sup>−1</sup> in FNrhF<sub>2</sub>.<sup>16</sup> This band position is red-shift by 153.8 cm<sup>−1</sup> compared to the free NF radical (1119.4 cm<sup>−1</sup>),<sup>12</sup> indicating a strong interaction between

**Table 1** Experimentally observed vibrational frequencies ( $\text{cm}^{-1}$ ) and isotopic frequency shifts ( $\text{cm}^{-1}$ ) (in parentheses) of the  $\text{M}(\text{NF}_3)$  and  $\text{FNMF}_2$  ( $\text{M} = \text{Pd, Pt}$ ) complexes in solid matrices (neon and argon) in comparison with quantum-chemical calculations. Calculated IR intensities ( $\text{km mol}^{-1}$ ) are provided in square brackets (absorption bands above  $400 \text{ cm}^{-1}$  are listed)

<sup>a</sup> Absorption bands not observed or too weak. <sup>b</sup> Harmonic frequencies calculated at the B3LYP/aug-cc-pVTZ(-PP) and CCSD(T)/aug-cc-pVTZ(-PP) levels are listed for the  $^{106}\text{Pd}$  and  $^{195}\text{Pt}$  isotopologues. The complete set of vibrational frequencies is provided in ESI Tables S1 and S2. For the CCSD(T) calculations no intensities are available. <sup>c</sup> Tentative assignments based on calculated vibrational displacement vectors.

nitrogen and palladium. Two low bands are attributed to the  $\text{PdF}_2$  antisymmetric and symmetric stretching modes, which are lower than  $652.1$  and  $586.1 \text{ cm}^{-1}$  in  $\text{OPdF}_2$ .<sup>22</sup> The palladium isotope pattern of these bands is not resolved, and only the band at  $575.5 \text{ cm}^{-1}$  displays a small  $0.4 \text{ cm}^{-1}$  shift with the  $^{15}\text{NF}_3$  sample. The Pd-N stretch is too weak to be observed. The  $\text{FNPDf}_2$  complex in solid neon is observed at  $968.0$ ,  $625.5$  and  $588.0 \text{ cm}^{-1}$ . The band positions are  $2.4$ ,  $13.2$  and  $2.3 \text{ cm}^{-1}$  blue-shifted from argon to neon. The observation of **B** directly after sample deposition indicates that it can be generated during the sample deposition process initiated by the excitation from the ablation plume.

Similar absorption bands are also observed in the platinum experiments. The product absorption bands at  $849.5$  and  $696.3 \text{ cm}^{-1}$  labeled **C** (Fig. 2, trace c) are assigned to the  $\text{Pt}(\text{NF}_3)$  complex. These bands shifted to  $825.4$  and  $678.6 \text{ cm}^{-1}$  with  $^{15}\text{NF}_3$ , and only the pure isotopic counterparts were observed in the  $1:1$  mixed  $^{14}\text{NF}_3 + ^{15}\text{NF}_3$  experiment. The band positions and isotopic frequency shifts ( $24.1$  and  $17.7 \text{ cm}^{-1}$ ) are close to those of the  $\text{Pd}(\text{NF}_3)$  complex, indicating similar bonding mode between palladium and platinum. The bands at  $883.6$ ,  $790.8$ ,  $643.4$  and  $611.5 \text{ cm}^{-1}$  labeled **D** (Fig. 2, trace d) that appeared upon co-deposition and increased after blue LED ( $\lambda = 470 \text{ nm}$ ) light irradiation are assigned to the  $\text{FNPtF}_2$  molecule. The  $^{15}\text{NF}_3$  counterparts are detected at  $862.4$ ,  $770.6$ ,  $643.4$  and  $611.3 \text{ cm}^{-1}$  with isotopic shifts of  $21.2$ ,  $20.2$ ,  $0$  and  $0.2 \text{ cm}^{-1}$ . These absorption bands belong to the F-N and Pt-N stretching vibration as well as  $\text{PtF}_2$  antisymmetric and symmetric stretching modes. The  $\text{Pt}(\text{NF}_3)$  and  $\text{FNPtF}_2$  complexes are detected at  $849.5$ ,  $696.3$  and  $890.4$ ,  $798.7$ ,  $653.6$ , and  $622.6 \text{ cm}^{-1}$  respectively in solid neon. The photoisomerization reaction of metal nitrogen trifluoride complexes (**A** and **C**) to  $\text{FNMF}_2$  (**B** and

**D**) is reproducible in the neon matrix. No similar product absorption bands are observed in the  $\text{Ni} + \text{NF}_3$  experiments.

The structures and vibrational frequencies of  $\text{M}(\text{NF}_3)$  and  $\text{FNMF}_2$  ( $\text{M} = \text{Pd, Pt}$ ) in the closed shell singlet ground state were calculated at the B3LYP/aug-cc-pVTZ(-PP) and CCSD(T)/aug-cc-pVTZ(-PP) levels (for details see the ESI†). Among the four isomers, the  $\text{FNMF}_2$  isomer has the lowest energy (Fig. S7†). As shown in Fig. 3, the  $\text{Pd}(\text{NF}_3)$  and  $\text{Pt}(\text{NF}_3)$  complexes possess an  $^1\text{A}_1$  electronic ground state and nitrogen trifluoride is coordinated to the metal center through nitrogen forming a  $C_{3v}$  structure. The triplet states of  $[\text{Pd}(\text{NF}_3)]$  and  $[\text{Pt}(\text{NF}_3)]$  are less stable by  $33.0$  and  $25.1 \text{ kcal mol}^{-1}$  at the CCSD(T)/aug-cc-pVTZ(-PP)/B3LYP/aug-cc-pVTZ(-PP) level. The N-F bond distance in the nitrogen trifluoride ligand is significantly longer ( $1.399 \text{ \AA}$  for Pd and  $1.409 \text{ \AA}$  for Pt) than in free nitrogen trifluoride ( $1.371 \text{ \AA}$ ).<sup>23</sup> The calculated Pd-N distance in the complex is slightly longer ( $2.073 \text{ \AA}$ ) than that of  $\text{PdNCCN}$  ( $1.948 \text{ \AA}$ )<sup>24</sup> and  $\text{PdNNO}$

**Fig. 3** Calculated structures (bond lengths in Ångstroms and bond angles in degrees) of  $\text{M}(\text{NF}_3)$  ( $\text{M} = \text{Pd, Pt}$ ) and  $\text{FNPtF}_2$  at the CCSD(T)/aug-cc-pVTZ(-PP) level and of  $\text{FNPDf}_2$  at the B3LYP/aug-cc-pVTZ(-PP) level of theory.

(2.003 Å).<sup>25</sup> The predicted Pt–N bond distance is 1.885 Å and close to that of 1.893 Å in the PtNNO complex.<sup>25</sup> The FNPD<sub>2</sub> and FNPF<sub>2</sub> molecules are predicted to have an <sup>1</sup>A' ground state with a *C*<sub>2</sub> symmetric structure, and are more stable than the Pd(NF<sub>3</sub>) and Pt(NF<sub>3</sub>) isomers by 41.6 and 80.9 kcal mol<sup>-1</sup>, respectively. The triplet FNPD<sub>2</sub> and FNPF<sub>2</sub> species are 9.8 and 16.6 kcal mol<sup>-1</sup> higher in energy than the corresponding molecules in the singlet state. The computed Pd–N distance of 1.705 Å in FNPD<sub>2</sub> is significantly shorter with respect to the Pd–N<sup>Dip</sup> bond length of 1.872(3) Å in the (CAAC)Pd(Dip) compound [CAAC = cyclic (alkyl)(amino)carbene, Dip = 2,6-diisopropylphenyl]<sup>26</sup> and in the range of those for calculated palladium nitrenes (1.8–2.0 Å).<sup>27</sup> The predicted Pt–N bond length of 1.743 Å and shorter than that of the linear two-coordinated platinum complex Pt(NC<sup>t</sup>Bu<sub>2</sub>)<sub>2</sub> [1.814(4) Å, 1.818(4) Å],<sup>28</sup> but longer than that of the binary molecule PtN (1.703 Å).<sup>29</sup> The short bond length and large <sup>14/15</sup>N isotopic shift indicate that the M–N bond in FNMF<sub>2</sub> is a double bond with a nitrene structure in which the metal shows a formal oxidation state +II, which are similar to the Rh–N bond in the FNRF<sub>2</sub> molecule.<sup>16</sup> The calculated structures of the F<sub>2</sub>NMF and NMF<sub>3</sub> (M = Pd, Pt) isomers are shown in Fig. S8.<sup>†</sup>

The assignment of the M(NF<sub>3</sub>) and FNMF<sub>2</sub> (M = Pd, Pt) complexes is supported by theoretical calculations at the B3LYP and CCSD(T) levels of theory. As listed in Table 1, similar to the FNRF<sub>2</sub> complex,<sup>16</sup> the calculated absorption band positions and observed experimental values of the F–N and N–M stretching frequencies in the FNMF<sub>2</sub> complexes do not match perfectly due to strong vibrational coupling between these two vibrational modes. Additionally, the predicted wavenumbers as well as isotopic shifts in other vibrational stretching modes in the complexes M(NF<sub>3</sub>) and FNMF<sub>2</sub> (M = Pd, Pt) show good agreement with the experimental values. All in all, the comparison between the computed and observed IR spectra strongly supports that the experimentally observed products are the nitrogen trifluoride complex M(NF<sub>3</sub>) and FNMF<sub>2</sub> (M = Pd, Pt) molecules. The calculated vibrational frequencies and intensities of the possible further isomers F<sub>2</sub>NMF and NMF<sub>3</sub> are shown in Tables S1 and S2.<sup>†</sup> However, both hypothetical isomers show different spectral signatures than our observed spectra, which further supports our assignment of the experimental bands. The relative energies (kcal mol<sup>-1</sup>) of different isomers of F<sub>3</sub>NM (M = Pd, Pt) are given in Table S3.<sup>†</sup>

The bonding of Pd(NF<sub>3</sub>) and Pt(NF<sub>3</sub>) complexes is of particular interest. By taking Pt(NF<sub>3</sub>) as an example. Fig. 4 shows the highest-lying occupied molecular orbitals. The HOMO and HOMO-1 are metal based 6s and 5d<sub>xy/x<sup>2</sup>-y<sup>2</sup></sub> nonbonding orbitals. The HOMO-2 is doubly degenerate metal d<sub>π</sub> orbital and composed of metal 5d<sub>xz/yz</sub> and the LUMO of nitrogen trifluoride. The HOMO-3 and HOMO-4 are only composed of ligand orbitals. The HOMO-5 is a ligand-based orbital that comprises some weak ligand to metal σ donation. Previous reports have proved that the bonding of lone-pair ligands to transition metals is generally consisted of σ donation from the ligand to the metal and π back-donation from the metal to the ligand.<sup>2</sup> Based on this assumption, the Pt 5d<sub>z<sup>2</sup></sub> orbital should be considered as an empty σ orbital to accept electron donation of

Fig. 4 Shape of the selected highest-lying occupied molecular orbitals of Pt(NF<sub>3</sub>) at the B3LYP/aug-cc-pVTZ level.

the NF<sub>3</sub> HOMO and the back-donation of the Pt π electrons to the NF<sub>3</sub> LUMO upon the formation of the Pt(NF<sub>3</sub>) complex. The donation interaction between the HOMO of NF<sub>3</sub> and a vacant Pt 5d<sub>z<sup>2</sup></sub> orbital with σ symmetry stabilizes the Pt–N and N–F bonds, while the back-donation from the Pt d<sub>π</sub> orbital to the NF<sub>3</sub> LUMO causes the destabilization of the N–F bond. Consistent with this notion, the N–F stretching frequencies of the Pt(NF<sub>3</sub>) complex are red-shifted compared to the neutral nitrogen trifluoride. The Pd(NF<sub>3</sub>) complex has a quite similar bonding situation to Pt(NF<sub>3</sub>). The palladium complex shows a lower N–F stretching frequency and the comparison with the platinum species suggests that the palladium complex has an even stronger back-donation. This shift can be explained by the different energy levels of the valence (*n* - 1)d and ns orbitals of the 4d and 5d transition metal atoms, which has been discussed for group 10 transition metal nitrous oxide complexes<sup>25</sup> as well as group 11 transition metal carbonyl complexes.<sup>30</sup>

The spectra illustrated in Fig. 1 and 2 clearly suggest that the N-coordination M(NF<sub>3</sub>) complexes are generated by the reactions of ground state palladium (<sup>1</sup>S) and platinum (<sup>3</sup>D) atoms with nitrogen trifluoride in solid neon and argon matrices. These association reactions are calculated to be exothermic by 11.0 (Pd), and 28.5 kcal mol<sup>-1</sup> (Pt) [CCSD(T)/aug-cc-pVTZ level], respectively, and require negligible activation energy, as the M(NF<sub>3</sub>) absorption bands increase on annealing, while a similar reaction product for nickel is predicted to be endothermic and was not observed. The bonding energies of nitrogen trifluoride are very close to those of the PdNNO and PtNNO complexes,<sup>25</sup> which are produced between Pd/Pt metals and nitrous oxide, but lower than that of PdNCCN and PtNCCN cyanogen complexes.<sup>24</sup> The M(NF<sub>3</sub>) complexes rearrange to the FNMF<sub>2</sub> isomers under blue LED ( $\lambda = 470$  nm) light irradiation. These isomerization reactions are computed to be exothermic by 41.6 (Pd) and 80.9 (Pt) kcal mol<sup>-1</sup> at the CCSD(T)/aug-cc-pVTZ(-PP)//B3LYP/aug-cc-pVTZ(-PP) level of theory. The isomeric pathway is predicted to proceed *via* two transition states involving the sequence M(NF<sub>3</sub>)

→  $\text{F}_2\text{NMF} \rightarrow \text{FNMF}_2$ . Fig. S9† shows the pathway where the first step  $\text{M}(\text{NF}_3) \rightarrow \text{F}_2\text{NMF}$  involves an activation energy barrier of 24.6 (Pd) and 19.1 (Pt) kcal mol<sup>-1</sup>. The second step  $\text{F}_2\text{NMF} \rightarrow \text{FNMF}_2$  requires to cross a lower barrier of 10.0 (Pd) and 17.6 (Pt) kcal mol<sup>-1</sup>. Both two energy barriers 34.6 (Pd) and 36.7 (Pt) kcal mol<sup>-1</sup> are lower than the energy of LED ( $\lambda = 470$  nm) light (60.8 kcal mol<sup>-1</sup>). Consistent with the low bonding energy, the  $\text{M}(\text{NF}_3)$  complexes underwent decomposition to form metal atoms and  $\text{NF}_3$  molecules when the matrix samples were subjected to blue LED ( $\lambda = 470$  nm) light photolysis and result in low efficiency to yield  $\text{FNMF}_2$  complexes. Further work is currently underway to study the reactions of group 10 metal atoms with phosphorus trifluoride ( $\text{PF}_3$ ).

## Conclusions

In summary, we described the formation of N-coordination nitrogen trifluoride complexes  $\text{M}(\text{NF}_3)$  (M = Pd, Pt) by the reaction of laser-ablated group 10 transition metal atoms with  $\text{NF}_3$  in solid neon and argon matrices. These molecular complexes were characterized by matrix-isolation infrared absorption spectroscopy and quantum-chemical calculations. The complexes rearrange to the  $\text{FNMF}_2$  isomer under blue LED ( $\lambda = 470$  nm) light irradiation, which is identified to be a fluoronitrenoid complex with a N–M double bond. The bonding in these nitrogen trifluoride complexes involves the electron donation of the HOMO of the nitrogen trifluoride to the empty metal  $d_{z^2}$  orbital and back-donation of the metal  $\pi$  electrons to the LUMO of nitrogen trifluoride. Although the detected metal nitrogen trifluoride products have low thermodynamic stability and can only be isolated in cryogenic matrices, they enrich and extend the arsenal of transition metal coordination chemistry and provide a deeper understanding of the fluorine specific interactions.

## Data availability

Data supporting this manuscript is available within the ESI† and available on request.

## Author contributions

GD planned and performed the experiments and carried out the quantum chemical calculations. He wrote the first draft of the manuscript. YL performed some of the experiments. TS helped with the design of the experiments and proof read the manuscript. SR guided and advised the project and proof read the manuscript.

We gratefully acknowledge the Zentraleinrichtung für Datenverarbeitung (ZEDAT) of the Freie Universität Berlin for the

allocation of computing resources. We thank the ERC Project HighPotOx as well as the CRC 1349 (SFB 1349) Fluorine Specific Interactions – Project-ID 387284271 – for continuous support. Open access funding was enabled and organized by Projekt DEAL. G. D thanks the Alexander von Humboldt Foundation (AvH) for a research scholarship.
