# Template-assisted synthesis of isomeric copper(I) clusters with tunable structures showing photophysical and electrochemical properties†

Jun-Jie Fang, Zheng Liu, Yang-Lin Shen, Yun-Peng Xie \* and Xing Lu \*

A comparative study of structure–property relationships in isomeric and isostructural atomically precise clusters is an ideal approach to unravel their fundamental properties. Herein, seven high-nuclearity copper(I) alkynyl clusters utilizing template-assisted strategies were synthesized. Spherical Cu<sub>36</sub> and Cu<sub>56</sub> clusters are formed with a [M@V(PO<sub>4</sub>)<sub>6</sub>] (M: Cu<sup>2+</sup>, Na<sup>+</sup>, K<sup>+</sup>) skeleton motif, while peanut-shaped Cu<sub>56</sub> clusters feature four separate PO<sub>4</sub> templates. Experiments and theoretical calculations suggested that the photophysical properties of these clusters are dependent on both the inner templates and outer phosphonate ligands. Phenyl and 1-naphthyl phosphate-protected clusters exhibited enhanced emission features attributed to numerous well-arranged intermolecular C–H⋯π interactions between the ligands. Moreover, the electrocatalytic CO<sub>2</sub> reduction properties suggested that internal PO<sub>4</sub> templates and external naphthyl groups could promote an increase in C<sub>2</sub> products (C<sub>2</sub>H<sub>4</sub> and C<sub>2</sub>H<sub>5</sub>OH). Our research provides new insight into the design and synthesis of multifunctional copper(I) clusters, and highlights the significance of atomic-level comparative studies of structure–property relationships.

## Introduction

During the past few decades, atomically precise metal nano-clusters have contributed significantly to the rapid development of nanomaterials by elucidating structure–property relationships.<sup>1–6</sup> Alkynyl ligands have more abundant coordination modes than the commonly used thiolate and phosphine ligands, and therefore alkynyl-protected coinage metal clusters have remarkable structures.<sup>7–11</sup> However, the reaction between alkynyl ligands and Cu<sup>+</sup> often produces insoluble polymers, which increases the difficulty of synthesis and isolation.<sup>12,13</sup> To address this issue, template agents have been introduced into the synthesis process to balance the charge distribution of the clusters and prevent or interrupt the formation of insoluble polymers resulting from the reaction between alkynyl and Cu<sup>+</sup>. As a result, the synthesis of high-nuclearity copper(I) alkynyl clusters with larger size and unique properties has been facilitated.<sup>14–17</sup>

Polyoxometalates (POMs) have attracted considerable attention due to their structural diversity and desirable properties in materials science, medicinal chemistry, and catalysis.<sup>18–20</sup>

Previous studies have reported silver alkynyl clusters with richer structures and more unique properties constructed with POMs.<sup>21–24</sup> Polyoxovanadates and polyoxomolybdates, both members of the POM family, constitute a fascinating family of polynuclear oxo-anions that exhibit variable coordination geometries, but have a strong tendency to exhibit mixed-valent states,<sup>25–27</sup> which leads to the easy oxidation of Cu<sup>+</sup>. This oxidizability significantly increases the difficulty in synthesizing copper(I) alkynyl clusters constructed with POMs.

Metal phosphonates not only exhibit various structures ranging from discrete molecules to multi-dimensional coordination polymers that provide a bridge for the construction of high-nuclearity metal clusters,<sup>28–30</sup> but also hold potential applications in biotechnology, water treatment, photochemistry, and magnetism.<sup>31–34</sup> We previously reported the use of (<sup>n</sup>Bu/<sup>t</sup>Bu)PO<sub>3</sub>H<sub>2</sub> as precursors to construct a series of silver clusters. (<sup>n</sup>Bu/<sup>t</sup>Bu)PO<sub>3</sub>H<sub>2</sub> units serve as tripod pillars that have a variety of coordination modes with metals and can be used as structure-directing templates to form enlarged composite clusters.<sup>23,24,35–37</sup> However, the reactions of polyoxometalates and phosphonates in this system are complicated, and V/P elements tend to exhibit multiple valent states that are prone to oxidize Cu<sup>+</sup>. Consequently, it is more difficult to synthesize copper(I) clusters with POM or phosphonate templates than silver(I) clusters. So far, only a few successfully synthesized copper(I) alkynyl clusters constructed with POM or phosphonate templates have been reported, including Mak's previously reported Cu<sub>33</sub>,<sup>38</sup> Cu<sub>46</sub>,<sup>39</sup> Cu<sub>47</sub>,<sup>39</sup> Cu<sub>62</sub> (ref. <sup>38</sup>) and our reported Cu<sub>25</sub>.<sup>40</sup>

Recently, atomically precise copper clusters and their correlations between structures and properties have received a lot of attention, particularly with regard to photoluminescence<sup>41,42</sup> and CO<sub>2</sub> reduction reaction (CO<sub>2</sub>RR).<sup>43–45</sup> For example, Jin *et al.* found that the phosphorescence quantum efficiency of M@Cu<sub>14</sub> (M: Au, Cl) nanoclusters can be tuned by a single-atom kernel.<sup>46</sup> Zang *et al.* observed that Au doping in the innermost shell of Au<sub>12</sub>(AgCu)<sub>38</sub> significantly enhances near-infrared photoluminescence intensity.<sup>47</sup> Bakr *et al.* reported that extended C–H⋯π and π⋯π intermolecular ligand interactions significantly enhance photoluminescence.<sup>48</sup> Atomically precise clusters with well-defined architectures and chemical compositions have attracted attention in the field of heterogeneous catalysis.<sup>49–53</sup> For instance, Liu *et al.* synthesized Cu<sub>32</sub>H<sub>20</sub>L<sub>12</sub> (L: S<sub>2</sub>P(O<sup>i</sup>Pr)<sub>2</sub>) exhibiting high selectivity (FE<sub>HCOOH</sub> = 89% at −0.3 V, 83% at −0.4 V) for the CO<sub>2</sub>RR.<sup>54</sup> Zang *et al.* observed that ditetrahedron-shaped Cu<sub>8</sub> exhibited a higher FE<sub>HCOOH</sub> (≈92%) at −1.0 V than the cube-shaped Cu<sub>8</sub>.<sup>55</sup> Tang *et al.* reported that M<sub>15</sub> (Au<sub>7</sub>Ag<sub>8</sub>, Ag<sub>9</sub>Cu<sub>6</sub>, and Au<sub>2</sub>Ag<sub>8</sub>Cu<sub>5</sub>) exhibits drastically different CO<sub>2</sub>RR performances in a wide voltage range.<sup>56</sup> These atomically precise clusters facilitate systematic comparative studies of structure–property relationships.

In this study, we designed a synthesis strategy to address the aforementioned challenges by adding weak reducing agents and phosphonate ligands, successfully synthesizing seven copper(I) alkynyl clusters. Single crystal structure analysis revealed that the structural modulation of these clusters can be achieved through the bonding of metal cations to templates. One Cu<sup>2+</sup>, Na<sup>+</sup>, or K<sup>+</sup> ion captured by six VO<sub>4</sub> or PO<sub>4</sub> tetrahedrons constructs a [M@{(V/PO)<sub>4</sub>}]<sub>6</sub> (M: Cu<sup>2+</sup>, Na<sup>+</sup>, K<sup>+</sup>) skeleton, which tends to form structurally similar spherical Cu<sub>36</sub> and Cu<sub>56</sub> clusters. Meanwhile, in the reaction system where Na<sup>+</sup> and K<sup>+</sup> ions are replaced with NH<sub>4</sub><sup>+</sup>, peanut-shaped Cu<sub>56</sub> clusters can be constructed from four PO<sub>4</sub> tetrahedrons. The crystalline-state emissions of these clusters depend on the inner templates and the outer phosphonate ligands. The surfaces of PhOPO<sub>3</sub><sup>2−</sup> and 1-NaphOPO<sub>3</sub><sup>2−</sup> protected clusters are interconnected through numerous well-arranged intermolecular C–H⋯π interactions between the ligands of adjacent clusters, leading to enhanced emission. Electrochemical measurements of CO<sub>2</sub> reduction reaction showed that PO<sub>4</sub>-encapsulated Cu<sub>56</sub> possesses higher catalytic activity for the CO<sub>2</sub>RR than VO<sub>4</sub>-encapsulated Cu<sub>56</sub>, and the PO<sub>4</sub> template and external naphthyl group can improve the yield of C<sub>2</sub> products (C<sub>2</sub>H<sub>4</sub> and C<sub>2</sub>H<sub>5</sub>OH).

## Results and discussion

### Synthesis and general characterization

The synthesis of clusters, [Cu<sup>II</sup>(VO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(<sup>t</sup>BuPO<sub>3</sub>)<sub>6</sub>(V<sub>3</sub>O<sub>3</sub>OH)(V<sub>3</sub>O<sub>6</sub>OH)(<sup>t</sup>BuC≡C)<sub>18</sub>] (1), [Cu<sup>II</sup>(VO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(<sup>t</sup>BuPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>26</sub>]F<sub>2</sub> (2), [Na<sup>I</sup>(PO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(<sup>t</sup>BuPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>26</sub>]F (3-Na), [K<sup>I</sup>(PO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(<sup>t</sup>BuPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>26</sub>]F (3-K), [Na<sup>I</sup>(PO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(PhOPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>26</sub>]F (3-PhOPO<sub>3</sub>, PhOPO<sub>3</sub> = phenyl phosphate), [Na<sup>I</sup>(PO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(1-NaphOPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>26</sub>]F (3-NaphOPO<sub>3</sub>, 1-NaphOPO<sub>3</sub> = 1-naphthyl

phosphate), [(PO<sub>4</sub>)<sub>4</sub>@Cu<sup>I</sup><sub>56</sub>(1-NaphOPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>32</sub>] (4), requires meticulous control over various phosphonates and vanadates.

To achieve this, we employed three different phosphonate ligands with varying steric hindrances to regulate their structures (Fig. 1). Reaction conditions were optimized to obtain the crystalline products, including the ratio of template precursors and (<sup>t</sup>Bu/Ph/O/1-NaphO)PO<sub>3</sub>H<sub>2</sub> ligands, time of ultrasonic conditions, amount of Et<sub>3</sub>N used, amount of PhMe<sub>2</sub>SiH added, and solvothermal temperature. Adjusting the addition ratio of NH<sub>4</sub>VO<sub>3</sub> and <sup>t</sup>BuPO<sub>3</sub>H<sub>2</sub> allowed us to obtain single crystals of 1 and 2. It should be noted that precise control of the amount of PhMe<sub>2</sub>SiH added was crucial to overcome the oxidizability of template precursors. Under natural light, the appearance of single crystals of 1–4 is dark red blocky and yellow blocky, respectively (Fig. S1†).

We elucidated the molecular structures of 1–4 through single crystal X-ray diffraction (SCXRD), and we have listed their crystal data, structure refinement, and selected bond lengths in ESI Tables 1, 2 and 5–12.† SCXRD analysis revealed that clusters 1 and 4 are both neutral clusters. While crystals of 1 and 4 are insoluble in common solvents, other crystals dissolve easily in CH<sub>2</sub>Cl<sub>2</sub>, CH<sub>3</sub>OH, and CH<sub>3</sub>CH<sub>2</sub>OH, providing opportunities to examine their solution stabilities and ionic valences using electrospray ionization mass spectrometry (ESI-MS). For example, in the positive ion mode ESI-MS of 2 dissolved in CH<sub>3</sub>OH and CH<sub>2</sub>Cl<sub>2</sub>, the two-charge prominent peaks centered at *m/z* = 3598.27 (2-a), 3608.24 (2-b), and 3617.23 (2-c) are assigned formulas of [Cu<sup>II</sup>@(VO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(<sup>t</sup>BuPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>25</sub>F<sub>2</sub> + H]<sup>2+</sup> (calcd *m/z* = 3598.54), [Cu<sup>II</sup>@(VO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(<sup>t</sup>BuPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>25</sub>F<sub>2</sub> + H<sub>2</sub>O + H]<sup>2+</sup> (calcd *m/z* = 3608.05), and [Cu<sup>II</sup>@(VO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>56</sub>(<sup>t</sup>BuPO<sub>3</sub>)<sub>6</sub>(<sup>t</sup>BuC≡C)<sub>25</sub>F<sub>2</sub> + (H<sub>2</sub>O)<sub>2</sub> + H]<sup>2+</sup> (calcd *m/z* = 3617.05), respectively (Fig. 2). We accurately identified other species produced by ionization of one or two <sup>t</sup>BuC≡C<sup>−</sup> ligands from the cations of the pristine clusters or by

(b) Molecular structures of <sup>t</sup>BuPO<sub>3</sub>H<sub>2</sub>, PhOPO<sub>3</sub>H<sub>2</sub>, and 1-NaphOPO<sub>3</sub>H<sub>2</sub> ligands. Color codes: P, purple; O, red; C, gray. Hydrogen atoms are omitted for clarity.

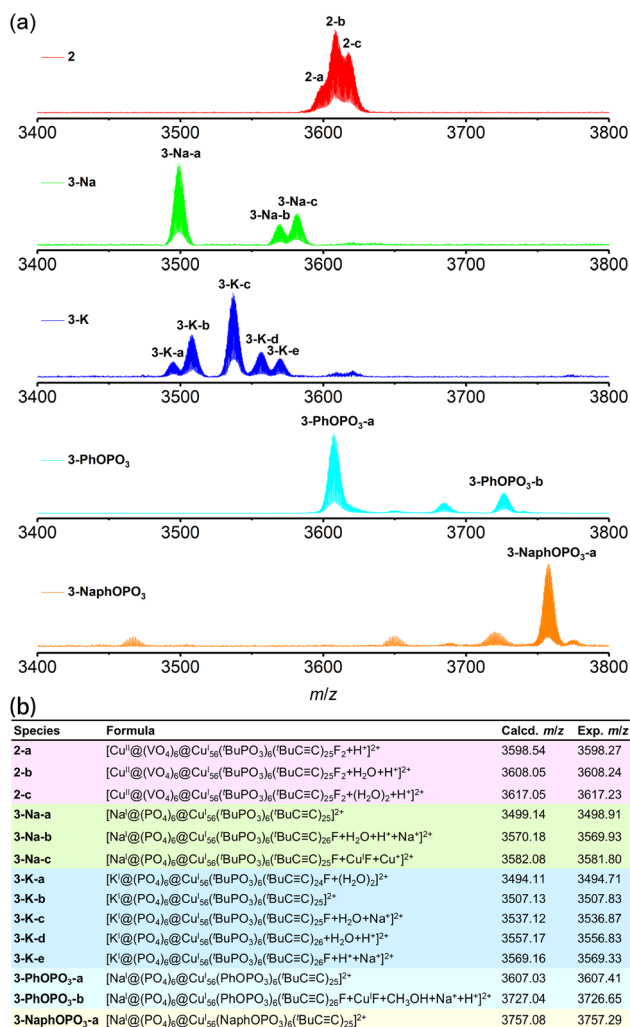

Fig. 2 Electrospray ionization mass spectra. (a) Experimental isotope distributions of selected peaks for 2–3-NaphOPO<sub>3</sub> (positive-ion mode, dissolved in CH<sub>2</sub>Cl<sub>2</sub> and CH<sub>3</sub>OH mixed solution). (b) The table is the formula assignment for these peaks.

further addition of H<sup>+</sup>, Na<sup>+</sup>, or H<sub>2</sub>O, indicating that these clusters are well stabilized in solution (Fig. S10–S15†).

Powder X-ray diffraction (PXRD) patterns of them *versus* the calculated patterns from single-crystal X-ray diffraction revealed their high phase purity, as shown in Fig. S16†. Their good thermal stability under the crystalline-state below 220 °C is exhibited in their thermogravimetric analysis (TGA) diagrams (Fig. S17†). Taking sample 2 as an example, the major weight loss (56.9%) in the range of 300–440 °C corresponds to a large proportion of ligand (tBuC≡C<sup>−</sup> and tBuPO<sub>3</sub><sup>2−</sup>) decomposition, with a second weight loss (1.5%) between 440 and 800 °C that may be attributed to a fraction of ligand (tBuC≡C<sup>−</sup> and tBuPO<sub>3</sub><sup>2−</sup>), Cu<sup>I</sup>, and [VO<sub>4</sub>]<sup>3−</sup> volatilization. The Fourier transform infrared (FT-IR) spectra confirmed the existence of alkynyl (2090 cm<sup>−1</sup>) in these clusters (Fig. S18†).

### Crystal structures of 1–4

Metal clusters can be synthesized using a variety of building blocks, and as previously reported, cap-shaped

Fig. 3 The detailed structure analysis of 1 and 2. VO<sub>4</sub> tetrahedrons are highlighted in green. (a) [Cu<sup>II</sup>(VO<sub>4</sub>)<sub>6</sub>@(tBuPO<sub>3</sub>)<sub>6</sub>(V<sub>3</sub>O<sub>3</sub>OH)(V<sub>3</sub>O<sub>6</sub>OH)]<sup>18−</sup> skeleton. (b) [Cu<sub>36</sub>(tBuC≡C)<sub>18</sub>]<sup>18+</sup> ring. (c) Overview of the total structure of [Cu<sup>II</sup>(VO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>36</sub>(tBuPO<sub>3</sub>)<sub>6</sub>(V<sub>3</sub>O<sub>3</sub>OH)(V<sub>3</sub>O<sub>6</sub>OH)(tBuC≡C)<sub>18</sub>]<sup>18−</sup>. (d) [Cu<sup>II</sup>@(VO<sub>4</sub>)<sub>6</sub>]<sup>16−</sup> kernel. (e) Wreath-shaped [Cu<sub>24</sub>(tBuC≡C)<sub>18</sub>]<sup>6+</sup> ring. (f) Wheel-shaped [Cu<sup>II</sup>@(VO<sub>4</sub>)<sub>6</sub>@Cu<sub>24</sub>(tBuC≡C)<sub>18</sub>]<sup>10−</sup> unit viewed from the c-axis. (g) Cap-shaped [Cu<sub>16</sub>(tBuC≡C)<sub>4</sub>(tBuPO<sub>3</sub>)<sub>3</sub>]<sup>6+</sup> peripheral structural unit. (h) Wheel-shaped [Cu<sup>II</sup>@(VO<sub>4</sub>)<sub>6</sub>@Cu<sub>24</sub>(tBuC≡C)<sub>18</sub>]<sup>10−</sup> unit viewed from the b-axis. (i) Overview of the total structure of [Cu<sup>II</sup>@(VO<sub>4</sub>)<sub>6</sub>@Cu<sup>I</sup><sub>36</sub>(tBuPO<sub>3</sub>)<sub>6</sub>(tBuC≡C)<sub>26</sub>]<sup>2+</sup>. Color codes: Cu<sup>I</sup>, yellow; Cu<sup>II</sup>, light blue; V, green; P, purple; O, red; C, gray. Hydrogen atoms are omitted for clarity.

[VO<sub>2</sub>(OH)(tBuPO<sub>3</sub>)<sub>2</sub>]<sup>2−</sup>, [(VO<sub>2</sub>)(tBuPO<sub>3</sub>)<sub>2</sub>]<sup>3−</sup>, [V<sub>3</sub>O<sub>6</sub>(OH)(tBuPO<sub>3</sub>)<sub>3</sub>]<sup>4−</sup>, and [V<sub>4</sub>O<sub>8</sub>(tBuPO<sub>3</sub>)<sub>4</sub>]<sup>4−</sup> units have been found to be versatile for the anion-templated synthesis of high-nuclearity silver(i) clusters.<sup>24,37</sup> Herein we report the successful formation of copper clusters using [VO<sub>4</sub>]<sup>3−</sup>/[PO<sub>4</sub>]<sup>3−</sup> tetrahedrons and [(tBu/PhO/1-NaphO)PO<sub>3</sub>]<sup>2−</sup> ligands as demonstrated in Fig. 3. The resulting cluster 1 crystallizes in the R3c space group, being assembled from one penetrating [Cu<sup>II</sup>(VO<sub>4</sub>)<sub>6</sub>@(tBuPO<sub>3</sub>)<sub>6</sub>(V<sub>3</sub>O<sub>3</sub>OH)(V<sub>3</sub>O<sub>6</sub>OH)]<sup>18−</sup> skeleton and one [Cu<sub>36</sub>(tBuC≡C)<sub>18</sub>]<sup>18+</sup> ring at the waist with argentophilic Cu⋯Cu bond distances in the range 2.511–3.016 Å. The [Cu<sub>36</sub>(tBuC≡C)<sub>18</sub>]<sup>18+</sup> ring has a van der Waals diameter of approximately 19.8 Å (Fig. S2†). The oxidizability of vanadate *in situ* generated a Cu<sup>2+</sup> cation,<sup>39</sup> which is bridged by six [VO<sub>4</sub>]<sup>3−</sup> tetrahedrons, forming an elongated octahedral coordination geometry Cu<sup>II</sup>O<sub>6</sub>.

By reducing the addition of vanadates and reaction time, cluster 2 was successfully synthesized. Furthermore, clusters 3-Na, 3-K, 3-PhOPO<sub>3</sub>, and 3-NaphOPO<sub>3</sub> were obtained by replacing vanadates with phosphonates resulting in crystal structures similar to cluster 2. For instance, SCXRD analysis and ESI-MS revealed that the overall charge balance of cluster 2 against the cationic cluster is provided by two F<sup>−</sup> counteranions. As

shown in Fig. 3, spherical cluster **2** has a multishelled core architecture of  $\text{Cu}^{\text{II}}@(\text{VO}_4)_6@(\text{Cu}^{\text{I}}_{56}(\text{BuPO}_3)_6(\text{BuC}\equiv\text{C})_{26})$ , with argentophilic  $\text{Cu}\cdots\text{Cu}$  bond distances in the range 2.423–3.055 Å. Furthermore, the *in situ* generated  $\text{Cu}^{2+}$  cation is encapsulated in six  $[\text{VO}_4]^{3-}$  templates. The wreath-shaped  $[\text{Cu}_{24}(\text{BuC}\equiv\text{C})_{18}]^{6+}$  ring has a hexagonal inner  $\text{Cu}_{12}$  unit, which is connected with the  $[\text{Cu}^{\text{II}}@(\text{VO}_4)_6]^{16-}$  polyoxoanion template to form the wheel-shaped  $[\text{Cu}^{\text{II}}@(\text{VO}_4)_6@(\text{Cu}_{24}(\text{BuC}\equiv\text{C})_{18})]^{10-}$  unit with a van der Waals diameter of about 20.4 Å (Fig. S2†). Cluster **2** is formed by fusing two cap-like  $[\text{Cu}_{16}(\text{BuC}\equiv\text{C})_4(\text{BuPO}_3)_3]^{6+}$  peripheral structural units staggered exactly by  $60^\circ$  on the upper and lower sides of the wheel-shaped unit. The packing pattern of crystal **2** shows that these molecules are well-arranged through intermolecular  $\text{C}\cdots\text{H}\cdots\text{F}$  interactions (4.079, 4.119, and 4.244 Å) (Fig. S3†).

Both spherical copper clusters,  $\text{Cu}_{36}$  and  $\text{Cu}_{56}$ , have similar internal distorted octahedron kernels, which are often observed in POMs.<sup>57</sup> As shown in Fig. 4, internal elongated  $\text{MO}_6$  octahedron skeletons are regulated by external distinct cap-shaped units. Specifically, the  $\text{Cu}^{\text{II}}\text{O}_6$  octahedron of cluster **1** has  $\text{Cu}^{\text{II}}\cdots\text{O}_\text{V}$  ( $\text{O}_\text{V}$ : oxygen atom of the  $[\text{VO}_4]^{3-}$  templates) bond distances ranging between 2.071 and 2.083 Å, whereas the  $\text{Cu}^{\text{II}}\cdots\text{O}_\text{V}$  bond distances in cluster **2**, capped by  $[\text{Cu}_{16}(\text{BuC}\equiv\text{C})_4(\text{BuPO}_3)_3]^{6+}$  units, are longer and range between 2.265, 2.270 and 2.310 Å. Additionally, cluster **3-K** has a  $\text{K}^+$  ion core with a larger ion radius than the  $\text{Na}^+$  ion, causing a larger  $\text{KO}_6$  octahedron ( $\text{K}\cdots\text{O}_\text{P}$  ( $\text{O}_\text{P}$ : oxygen atom of the  $[\text{PO}_4]^{3-}$  templates) bond distances: 2.634, 2.635, and 2.669 Å) than the  $\text{NaO}_6$  octagonal. The steric hindrances of outer phosphonate ligands increase from  $\text{BuPO}_3^{2-}$ ,  $\text{PhOPO}_3^{2-}$  to  $1\text{-NaphOPO}_3^{2-}$ , resulting

in a gradual increase of the internal  $\text{NaO}_6$  octagon size and the change of the space group from  $P2_1/n$ ,  $C2/c$ , to  $P\bar{1}$ .

In the reaction system where  $\text{Na}_2\text{HPO}_3$  and  $\text{K}_2\text{HPO}_3$  are replaced by  $(\text{NH}_4)_3\text{PO}_3$ , cluster **4** can be constructed from  $\text{PO}_4$  tetrahedrons without the presence of  $\text{Na}^+$  or  $\text{K}^+$  ions. As shown in Fig. 5, cluster **4** possesses a peanut-shaped structure that consists of four separate  $[\text{PO}_4]^{3-}$  tetrahedrons, thirty-two  $\text{BuC}\equiv\text{C}^-$  ligands, six  $1\text{-NaphOPO}_3^{2-}$  ligands, and fifty-six  $\text{Cu}^+$  ions with argentophilic  $\text{Cu}\cdots\text{Cu}$  bond distances ranging from 2.401 to 3.056 Å. The absence of metal cations inside the cluster allows for the aggregation of  $[\text{PO}_4]^{3-}$  tetrahedrons into the cluster. Cluster substructures  $[(\text{PO}_4)_2@(\text{Cu}^{\text{I}}_{28}(1\text{-NaphOPO}_3)_3(\text{BuC}\equiv\text{C})_{16})]^{4+}$  are bridged by four  $1\text{-NaphOPO}_3^{2-}$  ligands, with each oxygen atom coordinated to one copper atom.

It is noteworthy that the replacement of  $\text{BuPO}_3^{2-}$  ligands with  $\text{PhOPO}_3^{2-}$  and  $1\text{-NaphOPO}_3^{2-}$  ligands leads to the

Fig. 4 Overview of the total structures of spherical  $\text{Cu}_{36}$  and  $\text{Cu}_{56}$  clusters, and their internal distorted  $\text{MO}_6$  ( $\text{M}$ :  $\text{Cu}^{2+}$ ,  $\text{Na}^+$ ,  $\text{K}^+$ ) octahedron kernels. (a) **1**, (b) **2**, (c) **3-Na**, (d) **3-K**, (e) **3-PhOPO<sub>3</sub>**, and (f) **3-1-NaphOPO<sub>3</sub>**. Color codes: Na, light blue; K, dark blue;  $\text{Cu}^{\text{I}}$ , yellow;  $\text{Cu}^{\text{II}}$ , sky blue; V, green; P, purple; O, red; C, gray. Hydrogen atoms are omitted for clarity.

Fig. 5 The detailed structure analysis of **4**.  $\text{PO}_4$  tetrahedrons are highlighted in pink. (a) Peanut-shaped  $[(\text{PO}_4)_4@(\text{Cu}^{\text{I}}_{56}(1\text{-NaphOPO}_3)_6(\text{BuC}\equiv\text{C})_{32})]$ . (b) Two asymmetric units of **4** bridged by four  $1\text{-NaphOPO}_3^{2-}$  ligands. (c) The intermolecular  $\text{C}\cdots\text{H}\cdots\pi$  interactions between  $1\text{-NaphOPO}_3^{2-}$  ligands of adjacent clusters in **4**. Color codes: Cu, yellow; P, purple; C, gray; O, red; H, white.

formation of numerous strong intermolecular C–H $\cdots\pi$  interactions between adjacent clusters. Fig. S6–S8† demonstrate how nearby 1-NaphOPO<sub>3</sub><sup>2−</sup> and <sup>t</sup>BuC $\equiv$ C<sup>−</sup> ligands in cluster **4** form intermolecular C–H $\cdots\pi$  interactions at distances ranging from 2.862 to 3.626 Å. In cluster **3-PhOPO<sub>3</sub>**, intermolecular C–H $\cdots\pi$  interactions (at distances of 3.479 and 3.754 Å) are formed by PhOPO<sub>3</sub><sup>2−</sup> ligands, while in cluster **3-NaphOPO<sub>3</sub>**, intermolecular C–H $\cdots\pi$  interactions (at distances of 2.821, 3.342, and 3.598 Å) are formed by 1-NaphOPO<sub>3</sub><sup>2−</sup> ligands. These strong interactions between adjacent clusters are crucial to their luminous properties.

The coordination modes of alkynyl and phosphonate ligands with Cu<sup>+</sup> result in a diverse range of crystal structures, as demonstrated in Fig. S9.† Seven coordination modes, including  $\mu_2\text{-}\eta^1_\sigma$ ,  $\eta^1_\pi$ ;  $\mu_3\text{-}\eta^1_\sigma$ ,  $\eta^1_\sigma$ ,  $\eta^1_\pi$ ;  $\mu_3\text{-}\eta^1_\sigma$ ,  $\eta^1_\pi$ ,  $\eta^1_\pi$ ;  $\mu_3\text{-}\eta^1_\sigma$ ,  $\eta^1_\sigma$ ,  $\eta^1_\sigma$ ;  $\mu_4\text{-}\eta^1_\sigma$ ,  $\eta^1_\sigma$ ,  $\eta^1_\sigma$ ,  $\eta^1_\sigma$ ;  $\mu_4\text{-}\eta^1_\sigma$ ,  $\eta^1_\sigma$ ,  $\eta^1_\pi$ ;  $\mu_4\text{-}\eta^1_\sigma$ ,  $\eta^1_\sigma$ ,  $\eta^1_\pi$ ,  $\eta^1_\pi$ , are observed. Overall, the introduction of multiple VO<sub>4</sub> and PO<sub>4</sub> tetrahedrons with abundant terminal oxygen atoms during the synthesis of copper(i) alkynyl clusters not only balances the positive charges on the Cu(i) shells, but also effectively prevents or interrupts insoluble polymers formed by the reaction of alkynyl with Cu<sup>+</sup>.

### Photophysical properties

The optical properties of seven Cu<sub>36</sub> and Cu<sub>56</sub> clusters in their crystalline state were investigated through a series of spectroscopic analyses (Fig. 6a). The absorption features of clusters constructed by VO<sub>4</sub> tetrahedrons were found to be similar. Similarly, the absorption features of clusters constructed by PO<sub>4</sub> tetrahedrons had peaks located at 200–400 and 720 nm (except **4**), indicating that the electronic structures of these clusters are similar and in agreement with the single crystal data. The analysis of the absorption spectra revealed that clusters constructed by PO<sub>4</sub> tetrahedrons have an optical band gap in the range of 1.93–2.64 eV (Fig. S19†).

Photoluminescence (PL) properties correlate with both the optical absorption behaviors and crystal structures.<sup>58,59</sup> The PL spectra of cluster **2** in its crystalline state showed emission peaks at 444, 468, 507, 572, 654, and 670 nm, indicating a mechanism of multiple-exciton emission (Fig. 6b). As the temperature decreased, the luminescence intensity increased slightly, while the peak position remained unchanged. No luminescence thermochromism was observed, indicating that temperature has little effect on the tight packing and bond lengths in the crystal structure (argentophilic Cu $\cdots$ Cu bond average distances of 2.723 Å and 2.710 Å were observed in **2** and **2-100 K**, respectively). Clusters **1** and **4** both exhibited yellow emission centered at 574 nm. Meanwhile, **2-Na**, **2-K**, **3-PhOPO<sub>3</sub>**, and **3-NaphOPO<sub>3</sub>** exhibited a main emission peak at 430 nm and a shoulder peak at 710 nm.

The photoluminescence quantum yield (PLQY) of these clusters ranges from 1.05% to 3.65% (ESI Table S3†). Clusters protected by PhOPO<sub>3</sub><sup>2−</sup> and 1-NaphOPO<sub>3</sub><sup>2−</sup> ligands exhibited three times higher luminescence intensity than those protected by <sup>t</sup>BuPO<sub>3</sub><sup>2−</sup> ligands. There was a slightly enhanced quantum yield for clusters protected by PhOPO<sub>3</sub><sup>2−</sup> and 1-NaphOPO<sub>3</sub><sup>2−</sup> ligands. The strong intramolecular C–H $\cdots\pi$  interactions

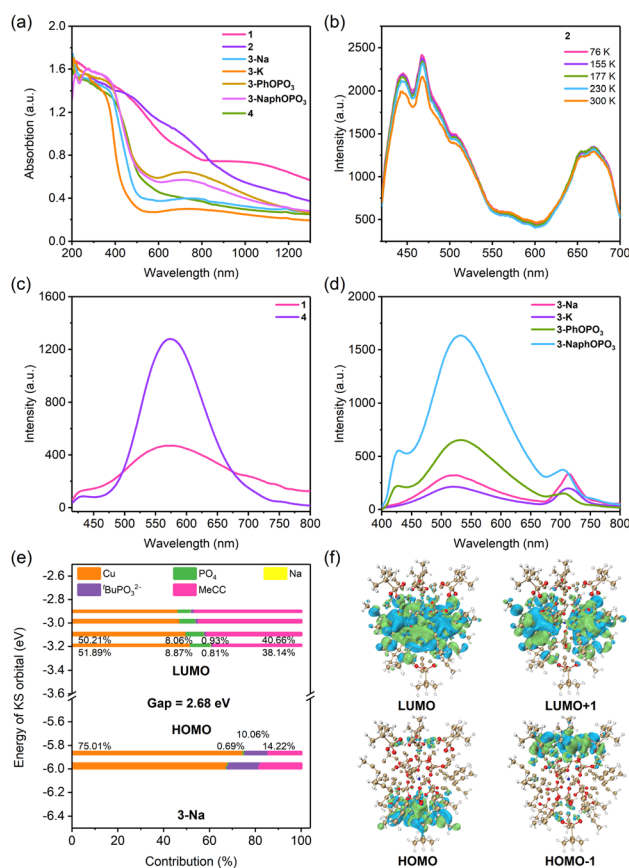

Fig. 6 Optical properties and electronic structures of clusters Cu<sub>36</sub> and Cu<sub>56</sub> in the crystalline state ( $\lambda_{\text{ex}}$  = 380 nm). (a) UV-Vis absorption spectra. (b) Temperature-dependent emission spectra of **2**. (c) Photoluminescence emission spectra of **1** and **4**. (d) Photoluminescence emission spectra of **3-Na**, **3-K**, **3-PhOPO<sub>3</sub>**, and **3-NaphOPO<sub>3</sub>**. (e) Composition analysis of frontier Kohn-Sham orbitals of **3-Na**. (f) Electronic density diagrams of the HOMO−1, HOMO, LUMO, and LUMO+1 of **3-Na** (isovalue = 0.010 a.u.).

connecting adjacent clusters restrict the rotation and vibration of some <sup>t</sup>BuC $\equiv$ C<sup>−</sup>, PhOPO<sub>3</sub><sup>2−</sup>, and 1-NaphOPO<sub>3</sub><sup>2−</sup> ligands and effectively decrease nonradiative decay, accounting for the enhanced emission. The PL lifetime decay curves of each metal cluster were examined to determine the key characteristics of their excited state dynamics. For **2**, decay curves of the 468 and 670 nm peaks were well fitted using a double exponential function, while other clusters required a triple exponential function for adequate fitting (Fig. S20–S22 and Table S3†). The exciton lifetimes  $\tau_1$  and  $\tau_2$  for the 670 nm peak of **2** at 300 K were determined to be 4.36 (97.72%) and 59.23 ns (2.28%), respectively, and were observed to remain relatively stable at different temperatures. In contrast, other clusters were found to have a contribution from microsecond lifetime processes; for example, in **3-Na**, the exciton lifetimes  $\tau_1$ ,  $\tau_2$ , and  $\tau_3$  for the 670 nm peak were determined to be 38.20 (62.79%), 361.17 (21.31%), and 2315.16 ns (15.90%), respectively.

To further elucidate the PL mechanism, density functional theory (DFT) calculations were performed using the ORCA 5.0.3 program.<sup>60,61</sup> Based on the single-crystal data, <sup>t</sup>BuC $\equiv$ C<sup>−</sup> was

replaced with  $\text{MeC}\equiv\text{C}^-$  to reduce the computational cost. In Fig. 6 and S23–S26,<sup>†</sup> the highest occupied molecular orbitals (HOMO and HOMO–1) of spherical  $\text{Cu}_{56}$  clusters were mainly located on the upper and lower cap-shaped structural units, while the lowest unoccupied molecular orbitals (LUMO and LUMO+1) were distributed on the wheel-shaped structural units at the waist. Comparative analysis of the contribution of different components to the LUMO and HOMO suggests that the PL mechanism arises from alkynyl  $\rightarrow \text{Cu}(\text{I})$   $^3\text{LMCT}$  (ligand to metal charge transfer) excited states that are modified by encapsulated templates and outer phosphonate ligands within the crystal structure.<sup>62</sup>

### Electrochemical properties

ESI-MS reveals that  $^t\text{BuC}\equiv\text{C}^-$  ligands can be isolated from the as-prepared clusters in solution. Fig. S27<sup>†</sup> illustrates the space-filling model structures of the spherical  $\text{Cu}_{56}$  clusters with the removal of a  $^t\text{BuC}\equiv\text{C}^-$  ligand exposing several active sites formed by the Cu atoms. These spherical  $\text{Cu}_{56}$  clusters have similar configurations while differing in terms of their encapsulated templates and external phosphonate ligands, which could result in distinct catalytic behaviors for the  $\text{CO}_2\text{RR}$ .<sup>55</sup>

We conducted electrochemical experiments on **2**, **3-Na**, and **3-NaphOPO<sub>3</sub>** clusters for the  $\text{CO}_2\text{RR}$  at different constant current densities ( $-50$  to  $-500 \text{ mA cm}^{-2}$ ) in a flow cell, analyzing the gas and liquid products by gas chromatography (GC) and  $^1\text{H}$  NMR, respectively. At low current densities  $\text{HCOOH}$ ,  $\text{CO}$ , and  $\text{H}_2$  are the primary products, while at higher current densities,  $\text{C}_2\text{H}_4$  and  $\text{C}_2\text{H}_5\text{OH}$  emerge in greater quantities (Fig. 7 and S28–S32<sup>†</sup>). Among these clusters, **3-Na** and **3-NaphOPO<sub>3</sub>** display similar  $\text{CO}_2\text{RR}$  properties. As the applied current density increases ( $-50$  to  $-500 \text{ mA cm}^{-2}$ ), the faradaic efficiency for  $\text{C}_1$  products initially rises and subsequently declines gradually, whereas the faradaic efficiency for  $\text{C}_2$  products ( $\text{FE}_{\text{C}_2\text{H}_4} + \text{FE}_{\text{C}_2\text{H}_5\text{OH}}$ ) generally increases over the same range

of current densities. Notably, **2** exhibits higher faradaic efficiency for  $\text{H}_2$  than **3-Na** and **3-NaphOPO<sub>3</sub>**. At a current density of  $-200 \text{ mA cm}^{-2}$ , **3-Na** demonstrates the highest faradaic efficiency for  $\text{C}_1$  products ( $\text{FE}_{\text{CO}} \sim 30\% + \text{FE}_{\text{HCOOH}} \sim 30\%$ ) and the lowest faradaic efficiency for  $\text{H}_2$  ( $\sim 17\%$ ). Under current densities ranging from  $-50$  to  $-500 \text{ mA cm}^{-2}$ , **3-NaphOPO<sub>3</sub>** displays higher  $\text{FE}_{\text{C}_2}$  products than the two other clusters, reaching up to  $\sim 45\%$  at  $-500 \text{ mA cm}^{-2}$ , with respective faradaic efficiencies for  $\text{C}_2\text{H}_4$  and  $\text{C}_2\text{H}_5\text{OH}$  of  $\sim 30\%$  and  $\sim 15\%$ . Compared with the  $\text{VO}_4$  template, the internal  $\text{PO}_4$  template and external naphthyl groups can promote C–C coupling, resulting in an increase in  $\text{C}_2$  products. This observation indicates that  $\text{CO}_2\text{RR}$  properties are not solely reliant on surface morphology but also influenced by the internal  $\text{VO}_4/\text{PO}_4$  tetrahedral template.

Moreover, we selected **3-Na** and **3-NaphOPO<sub>3</sub>** clusters with a higher  $\text{FE}_{\text{C}_1}$  as examples to evaluate their stability using chronoamperometric measurements. The current densities of gaseous products remained stable for at least 720 minutes, as shown in Fig. 7d and S29.<sup>†</sup> Despite minor fluctuations in the faradaic efficiencies of  $\text{CO}$ ,  $\text{C}_2\text{H}_4$ , and  $\text{H}_2$  at the start of the measurement, the overall current density remained relatively constant over the 720-minute period, indicating favorable catalytic sustainability. Finally, we compared these three clusters with atomically precise metal clusters exhibiting  $\text{CO}_2\text{RR}$  properties previously reported. As summarized in ESI Table 4,<sup>†</sup> it is worth noting that the  $\text{CO}$  selectivity of these three clusters is lower than that of gold clusters,<sup>45</sup> However, **3-NaphOPO<sub>3</sub>** exhibits better faradaic efficiency for  $\text{C}_2$  products, and copper, with its lower price, presents a more competitive alternative to gold.

## Conclusions

In conclusion, we present template-assisted strategies for the customization of seven high-nuclearity copper(I) alkynyl clusters at the atomic level. Single-crystal structural analysis reveals the multishelled core architecture of spherical  $\text{Cu}_{36}$  and  $\text{Cu}_{56}$  clusters assembled by a  $[\text{M}@\text{(V/PO}_4)_6]$  ( $\text{M}$ :  $\text{Cu}^{2+}$ ,  $\text{Na}^+$ ,  $\text{K}^+$ ) skeleton, while the peanut-shaped  $\text{Cu}_{56}$  cluster is constructed using four separate  $\text{PO}_4$  templates. The crystalline-state emissions of these clusters are dependent on the inner templates and outer phosphonate ligands. The enhanced luminescence observed can be attributed to numerous well-arranged intermolecular  $\text{C–H}\cdots\pi$  interactions between the ligands of phenyl and 1-naphthyl phosphate protected clusters. The electrocatalytic properties of  $\text{CO}_2$  reduction reaction are affected by both the surface morphology and the internal  $\text{VO}_4/\text{PO}_4$  template. Specifically, internal  $\text{PO}_4$  templates and external naphthyl groups could promote an increase in  $\text{C}_2$  products. This study provides ingenious strategies for tailoring the structures of nanoclusters at an atomically precise level and highlights the significance of atomic-level comparative studies of structure–property relationships.

## Data availability

All experimental and computational data are included in the ESI.<sup>†</sup> Crystallographic data for the structures reported in this

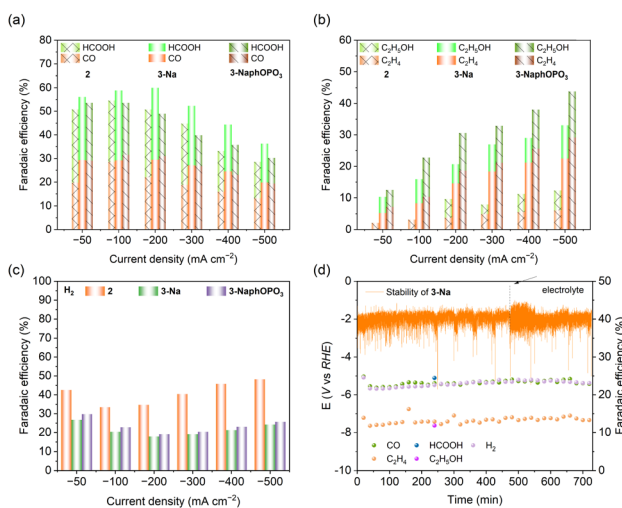

Fig. 7 Electrocatalytic performances. (a)–(c) Faradaic efficiencies of **2**, **3-Na**, and **3-NaphOPO<sub>3</sub>** at different applied current densities ( $0.5 \text{ M KHCO}_3$ ). (d) Stability tests of the electrocatalysts for  $\text{CO}_2$  reduction (**3-Na** at  $-200 \text{ mA cm}^{-2}$ ).
