Host miRNAs as biomarkers of SARS-CoV-2 infection: a critical review

Kato Pollet, ^{ab} Nathalie Garnier, ^{ab} Sabine Szunerits, ^b
 Annemieke Madder, ^c Didier Hober ^a and Ilka Engelmann ^{†*a}

MicroRNAs (miRNAs), small non-coding RNAs that regulate gene expression, have received increasing attention as potential biomarkers of different diseases, including viral infections. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection and the disease it is causing, coronavirus disease (COVID-19), has affected health, society and life worldwide since its pandemic spread. Differential expression of miRNAs in COVID-19 patients compared to healthy controls and also between different severity grades of COVID-19 has been described in several recent studies. In this review, we discuss in detail studies that investigated miRNA expression in body fluids of COVID-19 patients. Several studies found a different miRNA expression profile in COVID-19 patients compared to controls but also in different severity grades of the disease. We compared the main findings of the studies in order to identify miRNAs that have been identified as differentially expressed by more than one study and could serve as diagnostic or prognostic biomarkers of COVID-19. Finally, we highlight the challenges and perspectives associated to the use of miRNAs as biomarkers of COVID-19.

Introduction

A novel coronavirus, later named severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2), emerged in China at the end of 2019 and rapidly spread to cause a pandemic.^{1,2} SARS-CoV-2 belongs to the genus *Betacoronavirus* of the *Coronaviridae* family.² Coronaviruses are enveloped viruses with a positive-sense single-stranded RNA genome of 26–32 kb. Other members of this family are responsible for infections in humans, including the severe acute respiratory syndrome coronavirus

Kato Pollet

Kato Pollet is a PhD student at the University of Lille, in the Laboratory of Virology URL3610, working on the role of miRNAs in the pathogenesis of SARS-Coronavirus-2 infection. In 2019, she graduated with a bachelor's degree in "Pharmaceutical Sciences" at the University of Antwerp, Belgium. In 2021, she obtained a master's degree in "Drug development" at the University of Antwerp. She did internships in the laboratory of

Medical Biochemistry and in Pharmacy.

Nathalie Garnier

Nathalie Garnier is a PhD student at the University of Lille, in the Laboratory of Virology URL3610, working on the role of miRNAs in the pathogenesis of viral infections. In 2018, she graduated with a bachelor's degree in "Life Sciences" at the Sorbonne University in Paris. In 2020, she obtained a master's degree in "Virology" at the University of Strasbourg. She did internships at the Institute of Plant Sciences of Paris Saclay, at

the Laboratory of Bioimaging and Pathology in Strasbourg and at the Institute of Integrative Biology of the Cell of CNRS.

(SARS-CoV), the Middle East respiratory syndrome coronavirus (MERS-CoV), associated with severe disease, and viruses associated with clinically less severe infections, namely HCoV-OC43, HCoV-229E, HCoV-HKU1, HCoV-NL63.³

SARS-CoV-2 causes COVID-19, a disease presenting symptoms including fever or chills, cough, shortness of breath, fatigue, nausea, muscle ache, headache, nausea or vomiting, diarrhoea, sore throat, congestion or running nose, loss of smell (anosmia) and loss of taste (ageusia). Severity ranges from asymptomatic to critical illness with multi-organ failure, respiratory failure or shock and possible fatal outcome.⁴

Severe COVID-19 is associated with severe pulmonary disease and can present acute respiratory distress syndromes (ARDS), cardiac impairment, liver dysfunction, acute kidney injury and coagulopathy.⁵ A hyperinflammatory state termed cytokine storm contributes further to severe COVID-19.^{6,7} An imbalanced host immune response characterized by reduced type I interferon production and high expression of other cytokines has been suggested to drive severe COVID-19.^{8,9} TNF- α , IL-6, IL-8 and IL-10 are significantly elevated in patients with severe COVID-19.^{6,7,9}

miRNAs are small, noncoding RNAs that regulate gene expression. They bind to sequences that are often localized in

Sabine Szunerits

Sabine Szunerits graduated in chemistry from Queen Mary and Westfield College (University of London) and undertook postdoctoral work at the ENS Paris, Tufts University, Boston, ENSCPB, Bordeaux, and CEA Grenoble, France before starting her independent research career as Professor in 2004 at the INP Grenoble. Since 2009 she has been Full Professor at the University of Lille. Her research interests focus on the use of materials science and chemistry to tackle unmet medical and biosensing related problems. She is currently one of the Editors of Analytical and Bioanalytical Chemistry. In 2021 she was appointed as one of the two Editors in Chief of the RSC Journal Sensors and Diagnosis. In 2022, she was elected member of the American Institute for Medical and Biological Engineering (AIMBE).

Annemieke Madder

Prof. Dr. Annemieke Madder obtained her Ph.D in organic chemistry from Ghent University in 1997. Subsequently, she went for postdoctoral stays at the University of Milan and at the Karolinska Institute in Sweden. She returned to Ghent to take up tenure as assistant professor in 2002 and start her independent career. She was promoted to Professor at the Department of Organic and Macromolecular Chemistry in 2014 and Full Professor in 2022. Currently she is heading the Organic and Biomimetic Chemistry Research Group specializing in the design and synthesis of modified peptides and nucleic acids and methods for their conjugation and labeling.

Didier Hober

Professor of Virology, School of Medicine, University of Lille. Head of Department of Virology, School of Medicine, University of Lille. Head of Research Unit "Laboratoire de Virologie ULR3610", University of Lille and CHU Lille. Head of Service of Virology, CHU Lille. H factor: 48 (Google Scholar), publications: 271 in PubMed.

Ilka Engelmann

Ilka Engelmann graduated in medicine and specialized in microbiology. From 2004 to 2008, she worked as a virologist at Medizinische Hochschule Hannover, Germany. From 2008 to 2011, she did postdoctoral research at the Centre d'Immunologie de Marseille-Luminy, France. From 2011 to 2022, she was University lecturer at Lille University and staff virologist at Lille University Hospital, France. Since September 2022, she has been University lecturer at the University of Montpellier, staff virologist at Montpellier University Hospital and researcher at UMR1058 "Pathogenesis and Control of Chronic and Emerging Infections". She developed specific interest in the role of miRNAs in viral infections.

the 3'untranslated region (3'UTR) of a messenger RNA (mRNA) and inhibit translation or induce degradation of this mRNA.^{10–12} Biogenesis of miRNAs includes transcription by RNA polymerase II to pri-miRNAs that are further processed by Drosha giving rise to pre-miRNAs. Export to the cytoplasm is followed by Dicer processing, which generates miRNA duplexes that are loaded into an Argonaute protein to form a miRNA induced silencing complex (miRISC).^{12,13} miRNAs are involved in virtually all physiological and pathological processes, including viral infections and the antiviral immune response.¹³ As discussed in some recent work, viral infections change the expression profile of cellular miRNAs

(Fig. 1A).^{14–16} We recently reviewed data showing that acute and persistent enterovirus infection induced distinct miRNA expression changes in infected cells.^{15,17} Furthermore, different enterovirus types induced different miRNA expression changes and these were dependent on the cell type and the time point after infection.¹⁵ Concerning respiratory virus infections, Martinez-Espinoza and colleagues showed that infections with influenza A virus, human respiratory syncytial virus (HRSV), human metapneumovirus (HMPV), adenovirus and SARS-CoV-2 influenced the miRNA expression profile of different cell types *in vitro* but also in the blood of patients.¹⁶ Wu and

Fig. 1 Virus infection changes miRNA expression. A. Virus infection induces distinct changes of miRNA expression in different cell types and tissues. B. Virus infection induces miRNA expression changes in the blood and other body fluids of humans. These can be used as biomarkers.

colleagues reviewed data of HRSV and HMPV infections, demonstrating that these viruses induced distinct miRNA expression changes in different cell types *in vitro* and in clinical samples.¹⁴ These findings all point to miRNAs being important biomarkers for viral infections and being involved in the pathophysiology of viral infections.

miRNAs as biomarkers

miRNAs can be detected in several body fluids including plasma, serum, urine, saliva and semen.¹⁸ They are remarkably stable in these body fluids and storage for 24 hours at room temperature and up to ten freeze-thawing cycles had minimal impact on plasma and serum miRNA levels.^{19–23} The concentration of miRNAs in body fluids is known to change during various cancers and infectious diseases^{23–26} making miRNAs attractive candidates as biomarkers for viral infections and possibly allowing to distinguish an infected person from healthy controls (Fig. 1B).^{20,26–28} miRNA expression changes were documented in several viral infections, such as hepatitis B, hepatitis C, enterovirus infection, varicella, or influenza virus infection.^{26–28} Six miRNAs indeed allowed discriminating patients with enterovirus infections from healthy controls with areas under curve (AUC) above 0.80. A combination of these miRNAs resulted in a sensitivity of 97.1% and a specificity of 92.7% demonstrating a promising diagnostic performance.²⁹ miRNAs may also serve as prognostic biomarkers, *i.e.* distinguish between different grades of disease severity. For example, hsa-miR-150 levels were significantly higher in patients with severe influenza A/H1N1 disease and hsa-miR-876-5p expression was 9.5-fold higher in patients with severe enterovirus 71 infection when compared to patients with milder disease.^{30,31}

In the recent literature, studies reporting miRNA expression in COVID-19 patients have been published (Tables 1 and 2). Some of these aimed to identify miRNAs as biomarkers, whereas others included miRNA expression analysis as part of Omics approaches. Several studies also investigated a small number of preselected miRNA candidates. The objective of this review was to summarize data on the expression of miRNAs in body fluids of COVID-19 patients. These miRNAs have the potential to represent candidate biomarkers. We systematically searched for studies that describe human miRNA expression in body fluids of COVID-19 patients and reviewed studies that specifically investigated miRNAs as biomarkers for the diagnosis of SARS-CoV-2 infection and those that described miRNAs associated with different clinical courses of COVID-19.

Methods

For the elaboration of this review the PRISMA 2020 guidelines were followed.³²

Eligibility criteria

Studies that reported host miRNA expression in body fluids of COVID-19 patients and compared miRNA expression to healthy controls or between different severity groups of COVID-19 were included. Studies focusing on comparison of convalescent *versus* acute phase in COVID-19, after vaccination, compared to other diseases or between treatment responders and non-responders were not included.^{33–36} Studies with investigation of miRNA expression in tissues³⁷ were excluded because this specimen type would not be useful in routine for biomarker measurements. Studies that analyzed miRNA expression in COVID-19 restricted to a particular subpopulation, *e.g.* pregnant women,³⁸ were not included. Studies were grouped into studies that compared miRNA expression in COVID-19 patients *versus* controls and those that compared miRNA expression between different severity grades of COVID-19. Studies investigating miRNA expression in other than blood-derived specimen types were reported separately.

Information sources and search strategy

IE searched Pubmed (<https://pubmed.ncbi.nlm.nih.gov/>) on January 7th, 2022 with the search terms: “miRNA and COVID-19” and “miRNA and SARS-CoV-2”. These searches were performed in order to be exhaustive in the identification of potentially eligible studies. The two searches retrieved 380 and 312 articles respectively. Duplicate studies were removed, resulting in 379 studies for screening. Furthermore, four additional articles were identified by searching the reference lists of publications eligible for full-text review. Screening of studies was performed independently by two researchers (IE and KP) based on the content of the title and abstract. 75 full text articles were retrieved and 26 included in the review. Inconsistencies were discussed until consensus was obtained. A second search with the same search terms and same procedures was performed on April 6th, 2022, with the date limit January first, 2022 to April 6th, 2022. This search retrieved 75 and 54 articles for screening. Duplicates were removed resulting in 54 studies for screening of which 29 were retrieved and 14 were included. Furthermore, data of our study was included.³⁹ Fig. 2 presents the flow diagram combined for both searches. Data collection process: data was collected by one researcher (IE) and checked by two other researchers (KP and NG). Data collected was on differentially expressed miRNAs between COVID-19 patients and controls or different severity grades of COVID-19 patients. Furthermore, pre-analytical data, data on experimental procedures, normalization and statistical analysis was collected. Main differentially expressed miRNAs and study details were reported in Tables 1 and 2. A comparative analysis of differentially expressed miRNAs was performed and the miRNAs identified in the different studies reported in Table 1 were compared. Whenever possible, the information of the full name of the mature miRNA was retrieved from the articles, supplementary information, or

Studies with miRNA screening

Main findings	Patient numbers	Specimen type	Pre-analytical procedures	Extraction methods	miRNA quantification methods	Normalization methods	Statistical methods	Ref.
hsa-miR-3609, hsa-miR-199a-5p, hsa-miR-139-5p, hsa-miR-145-5p, hsa-miR-3651, hsa-miR-1273h-3p upregulated in severe <i>versus</i> mild COVID-19; hsa-miR-4632-5p, hsa-miR-6861-5p, hsa-miR-6802-5p, hsa-miR-5196-5p, hsa-miR-92b-5p, hsa-miR-6805-5p, hsa-miR-98-5p, hsa-miR-3185, hsa-miR-572, hsa-miR-371b-5p, hsa-miR-3180, hsa-miR-8073, hsa-miR-4750-5p, hsa-miR-6075, hsa-let-7i-5p, hsa-miR-1231, hsa-miR-885-3p downregulated in severe <i>versus</i> mild COVID-19	3 mild COVID-19 patients, 5 severe COVID-19 patients, 2 negative controls	Plasma	Centrifugation 15 min at 2000g, heat inactivation	Internal purification protocol of GenXPro GmbH, based on silica columns	TrueQuant small RNA kit (GenXPro GmbH), Illumina sequencing	Not indicated	DESeq, no correction for multiple testing mentioned	64
Upregulated in severe COVID-19: hsa-miR-4516, hsa-miR-362-5p, hsa-miR-548k, hsa-miR-320a-3p, hsa-miR-320b, hsa-miR-320c, hsa-miR-320d, hsa-miR-185-5p, hsa-miR-629-5p, hsa-miR-1180-3p, hsa-miR-502-3p; downregulated in severe COVID-19: hsa-miR-454-3p, hsa-miR-625-3p, hsa-miR-30b-5p, hsa-miR-192-5p, hsa-miR-451a, hsa-miR-197-3p, hsa-miR-29b-3p, hsa-miR-126-3p, hsa-miR-146b-5p, hsa-miR-30c-5p, hsa-miR-144-5p, hsa-miR-29a-3p, hsa-miR-363-3p, hsa-miR-99a-5p, hsa-miR-342-3p, hsa-miR-193b-3p, hsa-miR-190a-5p, hsa-miR-365b-3p, hsa-miR-122b-5p, hsa-miR-122-3p	32 severe, 52 moderate, 12 asymptomatic/mild COVID-19 patients, 13 controls	Plasma	Not indicated	miRNeasy Serum Plasma Advanced kit (Qiagen)	NEBNext Multiplex Small RNA Library Prep for Illumina (New England Biolabs), Illumina sequencing	DeSeq2	Generalized linear model with negative binomial distribution, FDR correction using the Benjamini-Hochberg method	65
Large number of differentially expressed miRNAs between the different groups; hsa-miR-22-3p and hsa-miR-3180-3p associated with lower probability of survival at 90 days and hsa-let-7f-1-3p, hsa-let-7g-5p, hsa-miR-1255a, hsa-miR-140-3p, hsa-miR-20a-5p, hsa-miR-363-5p, hsa-miR-4510, hsa-miR-6130 associated with better prognosis								

Table 1 (continued)

Studies with miRNA screening								
Main findings	Patient numbers	Specimen type	Pre-analytical procedures	Extraction methods	miRNA quantification methods	Normalization methods	Statistical methods	Ref.
Up in COVID-19: hsa-miR-6780b-3p, hsa-miR-6883-3p, hsa-miR-4769-5p, hsa-miR-6873-3p, hsa-miR-320b, hsa-miR-7111-3p, hsa-miR-4755-3p, hsa-miR-320c, hsa-miR-6511a-3p, hsa-miR-320d, hsa-miR-5187-3p, hsa-miR-4508, hsa-miR-4659a-5p; down in COVID-19: hsa-miR-4433b-5p, hsa-miR-16-2-3p, hsa-miR126-3p, hsa-miR-150-5p, hsa-miR-224-5p	4 mild COVID-19 patients, 4 severe/critical COVID-19, 4 controls	Plasma	Centrifugation at 2500 rpm at 4 °C for 10 min	miRNeasy Serum/Plasma Kit (Qiagen)	QIAseq miRNA Library Kit (Qiagen), Illumina sequencing	DESeq2	No correction for multiple testing mentioned	66
Down in severe <i>versus</i> mild COVID-19: hsa-miR-451a, hsa-miR-101-3p, hsa-miR-185-5p, hsa-miR-30d-5p, hsa-miR-25-3p, hsa-miR-342-3p, hsa-miR-30e-5p, hsa-miR-150-5p, hsa-miR-15b-5p, hsa-miR-29c-3p, hsa-miR-10b-5p, hsa-miR-16-2-3p, hsa-miR-186-5p, hsa-miR-16-5p, hsa-miR-425-5p, hsa-miR-187-3p, hsa-miR-125a-5p, hsa-miR-106b-3p, hsa-miR-22-3p, hsa-miR-144-5p, hsa-miR-151a-3p, hsa-miR-30a-5p, hsa-miR-92a-3p, hsa-miR-15a-5p, hsa-miR-195-5p, hsa-miR-4508, hsa-miR-194-5p, hsa-miR-140-3p, hsa-miR-142-5p, hsa-miR-99a-5p, hsa-miR-363-3p, hsa-let-7g-5p, hsa-miR-20a-5p, hsa-miR-144-3p, hsa-miR-10a-5p, hsa-miR-378a-3p, hsa-let-7f-5p, hsa-miR-660-5p, hsa-miR-3135b, hsa-miR-96-5p, hsa-miR-125b-5p, hsa-let-7i-5p	4 mild COVID-19 patients, 4 severe/critical COVID-19	Plasma	Centrifugation at 2500 rpm at 4 °C for 10 min	miRNeasy Serum/Plasma Kit (Qiagen)	QIAseq miRNA Library Kit (Qiagen), Illumina sequencing	DESeq2	No correction for multiple testing mentioned	66
Differentially expressed according to severity of COVID-19: hsa-miR-133a-3p, hsa-miR-122-5p, hsa-miR-126-3p, hsa-miR-21-5p, hsa-miR-197-3p, hsa-miR-320a-3p, hsa-miR-223-3p, hsa-miR-210-3p, hsa-miR-192-5p	Screening: 18 COVID-19 patients with mild to moderate disease, 18 with severe disease, 11 controls; validation: 6 mild, 39 moderate, 16 severe COVID-19 patients	Citrate/CTAD plasma	Centrifugation at 2000g for 15 min, 12 000g for 5 min	RNAseq: Maxwell RSC miRNA Tissue kit (Promega), RT-qPCR: miRNeasy Mini kit (Qiagen)	RNA-seq: RealSeq-Biofluids Plasma/Serum miRNA Library kit for Illumina sequencing (RealSeq Biosciences); RT-qPCR: miRCURY LNA RT kit (Exiqon), miRCURY LNA miRNA PCR	RNA-seq: not detailed; RT-qPCR: cel-miR-39-3p (Qiagen)	RNA-seq: the quasi-likelihood negative binomial generalized log-linear model functions of edge R v3.2828, DESeq2, Benjamini-Hochberg FDR correction; RT-qPCR: Student's <i>t</i> -tests/ Mann-Whitney <i>U</i> tests, using ANOVA	67

Up-regulated in COVID-19: hsa-miR-4443, hsa-miR-12116, hsa-miR-765, hsa-miR-1224-3p, hsa-miR-6886-3p, hsa-miR-6758-5p, hsa-miR-4716-5p, hsa-miR-1281, hsa-miR-6741-3p, hsa-miR-769-5p, hsa-miR-877-3p, hsa-miR-1469, hsa-miR-10401-5p, hsa-miR-7111-3p, hsa-miR-4646-3p, hsa-miR-204-3p, hsa-miR-7107-5p, hsa-miR-6510-5p, hsa-miR-6823-3p, hsa-miR-3196, hsa-miR-665, hsa-miR-7847-3p, hsa-miR-1268b, hsa-miR-139-3p; downregulated: hsa-miR-34b-3p	4 SARS-CoV-2-positive and 4 SARS-CoV-2-negative patients	Nasopharyngeal swabs	None	mirVana PARIS kit (Invitrogen)	Small RNA libraries were prepared using NEB Next Multiplex Small RNA Library Prep Set (Illumina)	DSeq2 median of ratios method	Unpaired two-tailed Mann-Whitney <i>U</i> test, not mentioned whether FDR was used	81

Fig. 2 PRISMA 2020 flow diagram for systematic reviews.

from technical information (namely, the Thermo Fisher Scientific Taqman miRNA assay ID). The direction of regulation (up- or downregulation) was also retrieved whenever possible. For studies that reported screening followed by validation, we took into account only validated miRNAs. For studies that only performed screening, the screening results were taken into account. Some studies lacked the information on whether the 3p or 5p form of the miRNA was differentially expressed, in which case we considered both forms. Some studies did not report whether miRNAs were up- or downregulated but only whether they were differentially expressed. These cases were still included in the analysis.

Figures

Figures were made by using images designed by Freepik (<https://fr.freepik.com>).

Results and discussion

A total of 41 studies met the inclusion criteria and were included in the review. Tables 1 and 2 show the main findings with pre-analytical and experimental details of these studies concerning miRNA expression measurements in blood-derived specimens (Table 1) and respiratory specimens (Table 2) given.

miRNAs in blood as biomarkers of SARS-CoV-2 infection

Several studies have investigated the correlation of miRNA dysregulation in patients suffering from severe to mild COVID-19 symptoms. Mainly blood-derived specimens from patients with different disease severity were used. The aim was to examine the differences in circulating miRNA expression in mild and severe disease as well as in healthy controls in order to identify miRNAs associated with COVID-

19 or COVID-19 severity. These studies have found several significantly dysregulated miRNAs (Table 1).

Diagnostic biomarkers

Several studies performed screening of miRNA expression and analyzed differential expression of miRNAs in COVID-19 patients compared to controls. In the study conducted by Fayyad-Kazan *et al.*, miRCURY LNA miRNome qPCR panels were used to identify differentially expressed miRNAs and a validation of miRNA candidates was performed by RT-qPCR (Table 1). hsa-miR-17-5p, hsa-miR-142-5p were both down-regulated whereas hsa-miR-15a-5p, hsa-miR-19a-3p, hsa-miR-19b-3p, hsa-miR-23a-3p, hsa-miR-92a-3p and hsa-miR-320a were up-regulated in 33 SARS-CoV-2-infected patients compared to 10 healthy controls.⁴⁰ The study contains a detailed description of methods used for quantification and normalization with the exception that it is not mentioned whether correction for multiple testing was performed (Table 1).

Sequencing was used in several studies to profile miRNA expression. Farr *et al.* reported 50 differentially expressed miRNAs between COVID-19 patients and healthy controls. They proposed three miRNAs (hsa-miR-423-5p, hsa-miR-23a-3p, hsa-miR-195-5p) that classified early SARS-CoV-2 infection accurately with an AUC = 1.0.⁴¹ A limitation of the study is the small patient number, especially for the comparison of COVID-19 with and without oxygen that was only based on 3 and 4 patients, respectively (Table 1). An additional comparison between COVID-19 patients and healthy controls was published by Li *et al.* in two articles.^{42,43} As far as miRNA expression is concerned, both articles seem to show the same data. The most differentially expressed miRNAs were hsa-miR-16-2-3p, hsa-miR-6501-5p, hsa-miR-618, hsa-miR-183-5p, hsa-miR-627-5p and hsa-miR-144-3p. However, fold-changes were moderate ranging from 1.3 to 2.3.⁴² This study is further limited by the small patient number and lack of description of whether a correction for multiple testing was used (Table 1).

Yang *et al.*⁴⁴ found differentially expressed miRNAs in COVID-19 patients compared to healthy controls: hsa-miR-19b-1-3p, hsa-miR-96, hsa-miR-19b-2-5p, hsa-miR-451a, hsa-miR-451b, hsa-miR-194-1-5p, hsa-miR-144, hsa-miR-486-2-3p, hsa-miR-15a, hsa-miR-29c-3p were downregulated in COVID-19 whereas hsa-miR-3609, hsa-miR-1244-1, hsa-miR-663a, hsa-miR-3916, hsa-miR-3687-2, hsa-miR-7846-3p, hsa-miR-5047, hsa-miR-3184-5p, hsa-miR-1248, hsa-miR-6891-3p were upregulated in COVID-19 patients. The small patient number remains a limitation of this study (Table 1).

Akula *et al.* found 8 differentially expressed miRNAs in plasma of COVID-19 patients compared to healthy controls by using sequencing and validation by RT-qPCR (Table 1).⁴⁵ Interestingly, hsa-miR-150-5p was subsequently shown to inhibit SARS-CoV-2 replication. Therefore, the observed downregulation of hsa-miR-150-5p in COVID-19 patients may promote SARS-CoV-2 replication.⁴⁵

A study with relatively large patient numbers identified several differentially expressed miRNAs between COVID-19 patients and controls (Table 1). Of note, the vast majority was downregulated in COVID-19: hsa-let-7i, hsa-let-7g, hsa-let-7f-2, hsa-let-7f-1, hsa-let-7d, hsa-miR-103a1, hsa-miR-126, hsa-miR-139, hsa-miR-15b, hsa-miR-16-1, hsa-miR-16-2, hsa-miR-181b1, hsa-miR-191, hsa-miR-21, hsa-miR-221, hsa-miR-222, hsa-miR-224, hsa-miR-23a, hsa-miR-23b, hsa-miR-25, hsa-miR-26a1, hsa-miR-30c1, hsa-miR-30c2, hsa-miR-30d, hsa-miR-320a, hsa-miR-92a1, hsa-miR-92a2, hsa-miR-93, hsa-miR-98, hsa-miR-151a, hsa-miR-340, hsa-miR-423, hsa-miR-425, hsa-miR-451a, hsa-miR-409, hsa-miR-454, hsa-miR-374b, hsa-miR-1244-1, hsa-miR-3609, hsa-let-7a2, hsa-let-7a1. Only three miRNAs were upregulated: hsa-miR-663b, hsa-miR-3687-2 and hsa-miR-3648-2.⁴⁶

Meidert *et al.* used NGS of serum-derived extracellular vesicles and identified several miRNAs dysregulated in patients with COVID-19 pneumonia compared to healthy controls. When RT-qPCR was used to validate the findings, hsa-miR-193a-5p and hsa-miR-197-3p were upregulated in COVID-19 pneumonia patients (Table 1).⁴⁷

Four studies investigated the expression of selected miRNAs by RT-qPCR: Donyavi *et al.* found that four specific miRNAs, hsa-miR-29a-3p, hsa-miR-146-3p, hsa-miR-155-5p and hsa-let-7b-3p were upregulated in PBMCs of COVID-19 patients compared to healthy controls.⁴⁸ ROC curve analysis revealed that hsa-miR-29a-3p, hsa-miR-146a-3p and hsa-miR-155-5p allowed discrimination between controls and COVID-19 patients. On the other hand, to distinguish post-acute from acute phase COVID-19, hsa-miR-29a-3p and hsa-miR-146-3p may be used.⁴⁸

Garg *et al.* included influenza infected patients in addition to COVID-19 and healthy controls. They found hsa-miR-21-5p, hsa-miR-155-5p, hsa-miR-499-5p upregulated in COVID-19 patients compared to healthy controls and influenza-ARDS patients. Hsa-miR-208a-3p was upregulated in both severe COVID-19 and influenza-ARDS groups compared to healthy controls. This shows that some miRNAs may be commonly dysregulated by different viral infections whereas others are dysregulated specifically.⁴⁹

In a large study, hsa-miR-10b-5p was found downregulated in the plasma of COVID-19 patients.⁵⁰ Wu *et al.* analyzed expression of 12 IFN signaling-related miRNAs in plasma of 29 COVID-19 patients and 29 controls and found higher levels of hsa-miR-29b-3p and hsa-miR-1246 levels in COVID-19 patients and lower hsa-miR-186-5p and hsa-miR-15a-5p lower in COVID-19 patients.⁵¹ One should note that plasma samples were heated in this study. These two studies report differential expression but did not perform ROC analysis to evaluate diagnostic performance of these miRNAs as biomarkers.

McDonald *et al.* measured hsa-miR-2392 expression by droplet digital PCR and found it upregulated in COVID-19 patients, in both serum and urine, and hsa-miR-2392 expression was higher in serum of COVID-19 patients necessitating ICU care.⁵² Hsa-miR-1-3p and hsa-miR-155-5p were downregulated in the serum of COVID-19 patients.⁵²

Abdolahi and colleagues used laboratory-developed RT-qPCR assays to quantify miRNA expression and found a downregulation of miR-200c-3p and miR-421-5p in COVID-19 patients.⁵³

miRNAs in blood associated with COVID-19 disease severity

Because miRNA expression not only differs between COVID-19 patients and healthy controls but also between severe and mild or moderate COVID-19, miRNAs may be useful as prognostic biomarkers for disease severity (Table 1).

Using sequencing, Tang *et al.* found that hsa-miR-146a-5p, hsa-miR-21-5p and hsa-miR-142-3p were downregulated whereas hsa-miR-3605-3p was upregulated in COVID-19 compared to healthy controls in whole blood after red blood cell lysis.⁵⁴ In contrast, hsa-miR-146a-5p was found upregulated in the serum of COVID-19 patients in another study.⁵⁵ Some miRNAs were upregulated only in patients with severe COVID-19, including hsa-miR-15b-5p, hsa-miR-486-3p and hsa-miR-486-5p, and some miRNAs were downregulated only in severe cases, including hsa-miR-181a-2-3p, hsa-miR-31-5p, and hsa-miR-99a-5p.⁵⁴ Another study limited by the small patient numbers and performing red blood cell lysis and sequencing, found hsa-miR-335-5p and hsa-miR-24-3p downregulated in severe COVID-19 (ref. 56) (Table 1). This leads to release of red blood cell miRNAs into the blood⁵⁷ and the authors thus measured a combination of miRNAs in blood cells, red blood cells and extracellular miRNAs.

Two studies used NGS and validation by RT-qPCR to identify miRNAs differentially expressed in different severity grades of COVID-19: a striking downregulation of the miR-320 family members including hsa-miR-320a, hsa-miR-320b and hsa-miR-320c was found in whole blood of patients with severe respiratory failure. Other strongly downregulated miRNAs were hsa-miR-4747-3p, hsa-miR-4429, hsa-miR-6729-3p and hsa-miR-1908-5p, with hsa-miR-374a-3p, hsa-miR-15a-3p, hsa-miR-3688-5p, hsa-miR-4721 being strongly upregulated in COVID-19 patients with severe respiratory failure.⁵⁸ The second study found that high serum levels of hsa-miR-320b and hsa-miR-483-5p were associated with a higher risk of mortality.⁵⁹ The discordance of the results concerning hsa-miR-320b may be due to the use of whole blood *versus* serum for miRNA expression measurements. This shows that the choice of the specimen type is very important and that expression of miRNAs differs between different blood fractions.

More so, Li *et al.* made a comparison between severe/critical and mild/moderate COVID-19 patients and investigated COVID-19 patients after recovery. This resulted in the observation that hsa-miR-155 and hsa-miR-130a were remarkably higher in the mild cases compared to severe/critical disease and healthy controls.⁶⁰ This study lacks on the other hand a detailed description of methods used for quantification and normalization of miRNA expression.

A study performed on 79 COVID-19 patients found that five miRNAs were up- and five miRNAs were downregulated in ICU COVID-19 patients compared to non ICU patients by using RT-qPCR⁶¹ (Table 1). However, the fold changes were modest. Hsa-miR-148a-3p, hsa-miR-486-5p and hsa-miR-451a were associated with ICU stay in multivariable analysis. Hsa-miR-16-5p, hsa-miR-92a-3p, hsa-miR-98-5p, hsa-miR-132-3p, hsa-miR-192-5p, hsa-miR-323a-3p were downregulated in patients who did not survive the ICU stay. The expression of two miRNAs, hsa-miR-192-5p and hsa-miR-323a-3p, predicted mortality during the ICU stay with an AUC of 0.80.⁶¹

Wilson *et al.* analyzed miRNA expression in plasma of 58 patients with mild, moderate or severe COVID-19 with Nanostring technology. A dysregulation of several miRNAs in severe COVID-19 was found, of which most were downregulated in severe COVID-19 (Table 1).⁶²

Parray *et al.* compared differential expression of miRNAs between three different COVID-19 severity groups. Multiple miRNAs were found upregulated and downregulated in severe *versus* asymptomatic COVID-19 as well as between severe and mild COVID-19 (Table 1).⁶³

Grehl and colleagues found 11 upregulated and 20 downregulated miRNAs in severe COVID-19 cases by next generation sequencing (Table 1).⁶⁴ This study was performed on a small number of patients and no correction for multiple testing was detailed in the article.

Another study compared the expression of miRNAs in severe, moderate, mild/asymptomatic COVID-19 patients and controls. They performed several comparisons between the different groups and found a large number of differentially expressed miRNAs. They further built a score based on the expression of ten miRNAs (hsa-miR-22-3p, hsa-miR-3180-3p, hsa-let-7f-1-3p, hsa-let-7g-5p, hsa-miR-1255a, hsa-miR-140-3p, hsa-miR-20a-5p, hsa-miR-363-5p, hsa-miR-4510 and hsa-miR-6130) that allowed to classify patients into low or high risk for mortality.⁶⁵

de Nicoletti *et al.* found several differentially expressed miRNAs between COVID-19 patients and uninfected controls as well as depending on COVID-19 severity (Table 1).⁶⁶ Only four patients per group were analyzed and it was not mentioned whether correction for multiple testing was applied.

A thoroughly conducted study that included a screening and a validation cohort found several differentially expressed miRNAs in COVID-19 patients with different disease severities⁶⁷ (Table 1). After adjustment for age and sex, hsa-miR-122-5p, and hsa-miR-133a-3p were the only miRNAs besides platelet- and endothelium-derived hsa-miR-126-3p that showed a significantly different expression in mild, moderate and severe COVID-19.⁶⁷ RT-qPCR measurements of hsa-miR-122-5p and hsa-miR-133a-3p classified patients into severe ($n = 16$) and non-severe ($n = 45$) COVID-19 with AUCs of 0.75 and 0.79, respectively.⁶⁷ Interestingly, hsa-miR-122-5p was also found in extracellular vesicles of COVID-19 patients and allowed to differentiate mild COVID-19 patients from

those who progressed to severe or critical disease with an AUC = 0.81.⁶⁸

Two studies specifically investigated the expression of hsa-miR-155. One found that hsa-miR-155 was overexpressed in COVID-19 *versus* controls, severe *versus* moderate COVID-19 and non-survivors *versus* survivors. AUC to distinguish COVID-19 patients from controls was 0.986 whereas for the distinction of severe and moderate patients AUC = 0.75.⁶⁹ The other study found hsa-miR-155 underexpressed in patients with COVID-19 compared to controls and underexpressed in patients who died compared to survivors with an AUC = 0.83 to differentiate survivors and non survivors.⁷⁰ These studies seem to have observed an opposite regulation of the same miRNA.

Keikha and coworkers published two articles on the expression of selected miRNAs in COVID-19. The first article reports that hsa-miR-31-3p, hsa-miR-29a-3p and hsa-miR-126-3p were decreased in more severe COVID-19 disease grades, whereas hsa-miR-17-3p was increased in more severe disease grades.⁷¹ Expression in healthy controls is not shown in the article. The second article, probably on the same cohort, showed that hsa-miR-21, hsa-miR-124, hsa-miR-146a were downregulated, whereas hsa-miR-326, hsa-miR-155, hsa-miR-27b were upregulated in COVID-19 patients with increased of disease severity.⁷²

Hsa-miR-4257 was downregulated in COVID-19 patients *versus* controls and in severe *versus* mild COVID-19 as reported by Agwa and colleagues.⁷³ ROC analysis revealed that hsa-miR-4257 expression could be used as biomarker to distinguish COVID-19 patients from controls with an AUC of 0.911.⁷³

Differential expression of two miRNAs was found by using whole serum of patients with severe and non-severe COVID-19, whereas ten distinct differentially expressed miRNAs were identified when using extracellular vesicles isolated from sera (Table 1).⁷⁴ This shows that the choice of the specimen type is very important and that expression of miRNAs differs between different blood fractions. Direct comparison of miRNA expression in different specimen types is therefore not recommended.⁷⁵

By using RNA-seq, another study found 20 differentially expressed miRNAs in serum-derived extracellular vesicles from patients with COVID-19 pneumonia compared to patients with COVID-19 ARDS. However, only one of these (hsa-miR-206) showed the same differential expression when RT-qPCR was used (Table 1).⁴⁷

In a relatively large study, six miRNAs, namely hsa-let-7a-5p, hsa-let-7d-5p, hsa-let-7f-5p, hsa-miR-98-5p, hsa-miR-340-5p, hsa-miR-378a-3p were found predictive of clinical outcome of COVID-19 among other biomarkers.⁷⁶

miRNAs in respiratory specimens

Lately, a few studies investigated miRNA expression in respiratory specimens of COVID-19 patients. This is of interest because it may be useful to identify biomarkers in

the same specimen type that is used for the diagnosis of SARS-CoV-2 infection by RT-PCR, *i.e.* nasopharyngeal specimens. This would avoid obtaining a blood specimen for biomarker measurement.

One study measured expression of hsa-miR-200c-3p in saliva of symptomatic non-hospitalized, hospitalized COVID-19 patients and patients without COVID-19 as well as in sublingual smears of ICU COVID-19 patients (severe group).⁷⁷ A higher expression of hsa-miR-200c-3p was found in the severe group (Table 2). However, given the difference in specimen types used in the different groups, this difference may be due to the different specimen type rather than the COVID-19 severity.⁷⁷ Of note, hsa-miR-200c-3p was found downregulated in the blood of COVID-19 patients in an independent study.⁵³

Molinero *et al.* studied miRNA expression in bronchial aspirate specimens of COVID-19 and non COVID-19 ICU patients. Rather than comparing the expression of single miRNAs, they compared expression ratios and found several differences of the expression of certain miRNA ratios when COVID-19 and non-COVID-19 as well as ICU survivors and nonsurvivors were compared (Table 2). They constructed a model for ICU mortality prediction and found that the best combination of miRNA ratios (hsa-miR-125b-5p/hsa-miR-34a-5p, hsa-miR-199a-5p/hsa-miR-9-5p, and hsa-miR-221-3p/hsa-miR-491-5p) had an AUC = 0.85 for predicting ICU mortality. The hsa-miR-199a-5p/hsa-miR-9-5p ratio showed an AUC = 0.80 for predicting ICU mortality.⁷⁸

Farr *et al.* investigated miRNA expression in anterior nares swabs and found six differentially expressed miRNAs between COVID-19 and uninfected patients (Table 2). Supervised machine learning identified a three-miRNA signature consisting of hsa-miR-30c-2-3p, hsa-miR-628-3p and hsa-miR-93-5p independently classified COVID-19 cases with 100% accuracy.⁷⁹

Eichmeier and colleagues identified 7 miRNAs in nasopharyngeal swabs by sequencing that were differentially expressed in COVID-19 positive and negative patients (Table 2). However, RT-qPCR comparison of the miRNA expression yielded different results.⁸⁰

Wu *et al.* studied miRNA expression in nasopharyngeal swabs specimens of 4 COVID-19 patients and 4 controls and identified several differentially expressed miRNAs, where most of them were upregulated in COVID-19 compared to controls (Table 2).⁸¹

We recently investigated miRNA expression in COVID-19 patients and found ten miRNAs associated with severe COVID-19 (Table 2). Interestingly, expression of most of these miRNAs was lower in severe than in non-severe COVID-19 patients. ROC analysis revealed that three of these miRNAs are promising candidate biomarkers for severe COVID-19, namely hsa-miR-125a-5p, hsa-miR-491-5p and hsa-miR-200b-3p. These miRNAs discriminated severe from non-severe cases with AUCs ranging from 0.76 to 0.79.³⁹

Comparison and overlap of miRNAs in different studies

When comparing the miRNAs identified in the different studies, the overlap is surprisingly small. As far as differential expression between COVID-19 patients and controls is concerned, 20 miRNAs were identified in at least two studies with the same deregulation when this was described. For studies, comparing the differential expression between different severity grades of COVID-19, the overlap was bigger: 35 miRNAs were identified in at least two studies with the same direction of deregulation when this was described. Applying more strict criteria, *i.e.* at least three studies with the same direction of deregulation when this was described, resulted in three miRNAs for the studies investigating differential expression between COVID-19 patients and controls, namely hsa-miR-126, hsa-miR-150-5p, hsa-miR-155. Interestingly, hsa-miR-155 was found downregulated in plasma and serum of COVID-19 patients in two studies,^{52,70} whereas it was found upregulated in plasma, serum, whole blood and PBMCs in four studies.^{48,49,60,69} Applying these stricter criteria for the studies investigating differential expression between different severity grades of COVID-19 resulted in six miRNAs, namely hsa-miR-126-3p, hsa-miR-140-3p, hsa-miR-192-5p, hsa-miR-451a, hsa-miR-98-5p, hsa-miR-99a-5p. These miRNAs can be considered as most robust and thus most promising but to be used as biomarkers.

The reasons for the small overlap of miRNAs identified as differentially expressed in the different studies are multiple. First, the choice of the patient population differs. Next, the definition of mild *versus* severe COVID-19 also is not uniform in the different studies. Another main factor is certainly the choice of the initial specimen: the use of whole blood, plasma, serum or extracellular vesicles. miRNAs found associated with severe COVID-19 were distinct when using serum or extracellular vesicles from serum.⁷⁴ Pre-analytical aspects and techniques used for miRNA extraction and expression profiling were also different (Tables 1 and 2). Normalization strategies and statistical methods were also diverse. Many studies did not report correction for multiple analyses and most did not validate their results in a validation cohort or by using a different technique. All these factors influence on the results.

Future perspectives and challenges

Before miRNA expression can be used in routine patient management, some challenges need to be overcome. These challenges are detailed in recent reviews^{75,82} and range from standardization of the specimen type, pre-analytical issues like specimen processing and storage, to data analysis and interpretation. The choice of the specimen type, including the blood fraction (plasma or serum) and anticoagulant (EDTA, heparin or citrate) influence both miRNA levels.⁵⁷ Impacts of potential confounders, including physiological factors (*i.e.* age and sex), body mass index, underlying

diseases and pharmacological treatments, on miRNA expression need to be taken into account.^{75,83,84} Pre-analytical factors, such as centrifugation and storage duration and temperature should be standardized. As far as analytical procedures are concerned, different RNA isolation protocols may impact the efficacy of small RNA isolation.^{75,82} Furthermore the technique chosen for miRNA quantification can impact on the results.⁸² The importance of controls used for monitoring of RNA extraction quality cannot be underestimated. Finally, the methods of normalization and statistical analyses also influence the results and should be critically reviewed.

Whereas the published studies reported relative quantification of miRNAs, the question of quantification for routine diagnostic use arises. Potentially, absolute quantification of miRNAs would be more useful in the routine diagnostic setting with cut-offs of miRNA expression levels associated with diagnostic or prognostic performance of the given miRNA to be defined.

The next steps may be to investigate influence of physiological factors on the expression of candidate biomarker miRNAs in order to determine whether age or sex influence their expression. The impact of infections with other viruses on their expression level also needs to be investigated in order to ascertain that the observed changes are specific to SARS-CoV-2 infection.

While a vast amount of data on miRNA expression in body fluids of COVID-19 patients is available, before the application of miRNAs as diagnostic or prognostic biomarkers, a number of technical and analytical issues have to be resolved first. Further studies with larger patient cohorts allowing for multivariable analysis taking into account confounding factors are necessary.
