rsc.li/sensors

In this study, we report the first combination of mid-infrared (MIR) interband cascade light emitting diodes (ICLEDs) with a central emission wavelength at 4.0 μm and 3.4 μm , respectively, combined with a substrate-integrated hollow waveguide (iHWG) for the detection of CO_2 and CH_4 analyzing the antisymmetric stretching of CO_2 at 2345 cm^{-1} , and the CH stretching rovibrational mode of CH_4 at 3020 cm^{-1} . The obtained calibration functions in the concentration range from 1000 to 10 000 ppm_v enabled deriving detection limits in the range of 386–407 ppm_v for CO_2 , and of 302–338 ppm_v for CH_4 . The combination of iHWG and ICLED technology is a pioneering step toward a new generation of miniaturized and low-cost mid-infrared optical sensing devices for rapid gas diagnostics and exceedingly small sample volumes.

Introduction

The need for low-cost yet bright light sources in the infrared spectral range from 2 to 20 μm has been growing in recent years. In particular, the 3–6 μm regime is of great importance for the detection of gaseous molecules in environmental analysis, process monitoring and even in biomedical diagnostics. In this spectral window, many relevant gases including but not limited to NH_3 (2.1 μm), CH_4 (2.35 μm and 3.3 μm), HCl (3.5 μm), N_2O (3.9 μm and 4.5 μm), SO_2 (4 μm), CO_2 (4.25 μm), and CO (2.3 μm and 4.6 μm) have molecule-specific vibrational, rovibrational, and rotational transitions.¹

Infrared spectroscopy with its inherent molecular selectivity is ideally suited for the selective, sensitive and rapid detection and/or monitoring of molecular constituents, and represents an effective alternative to conventionally used methods such as *e.g.*, gas chromatography coupled with mass spectrometry or other complex detection schemes. Furthermore, given recent developments in IR waveguide, light source, and detector technology,^{2–4} infrared spectroscopy shows unrivaled potential for molecular sensor miniaturization serving as a versatile and modular analytical tool.

Nowadays, the specific molecular vibrational, rovibrational, and rotational transitions in the MIR regime in a sensing format are typically excited by narrowband light sources such as quantum-cascade lasers (QCLs). QCLs were first experimentally described in 1994⁵ and are based on intersubband transitions between constructed conduction band states in complex heterostructures instead of electron–hole recombination in a semiconductor bandgap.^{6,7} These electron transitions lead to efficient photon emission in the MIR range enabling a wide variety of spectroscopic and sensing applications.^{8–11} These are mostly built on InGaAs/InAlAs material systems, which however are limited to wavelengths $\lambda > 5 \mu\text{m}$ due to conduction band offset. New QCL material systems have been researched,^{12–15} but they are less advanced in both fabrication and processing than the common InGaAs/InAlAs materials, and thus QCLs using such new materials are not yet well-developed.

An alternative to QCLs is provided by interband cascade lasers (ICLs), which were proposed and realized at about the same time as QCLs.^{16,17} ICLs are based on electron–hole recombination of type-II interfaces, where, for example, electrons of the InAs conduction band recombine with the holes of the InGaSb valence band. With this design, it is possible to operate ICLs in continuous wave (cw) mode at room temperature, at exceedingly low required electrical power and within a spectral wavelength range of 3–7 μm .

However, ICLs are not cost-efficient due to their design complexity, and are therefore of limited suitability for low-cost sensing applications. LED-like emitters are a cost-efficient alternative to lasers given their small dimensions,

long-term reliability and broadband, incoherent radiation emission characteristics. Interband cascade light diodes (ICLEDs) – similar to ICLs – use electron–hole recombination in type-II structures as their core radiation emission mechanism, however, do not have an upper and lower optical cladding layer. Owing to recent developments, ICLEDs can also be operated at room temperature in cw mode, are characterized by a very low electrical power consumption, and provide output powers in some cases >1 mW in the 3–8 μm range.^{18–24}

In addition to the light source, a compact combination with an appropriate waveguide and an efficient gas cell is required for the development of miniaturized gas sensors. Griffiths *et al.*²⁵ first reported an applied combination of waveguide and gas cell in the form of a so-called hollow waveguide (HWG) in the 1980s. An innovative alternative providing the combination of an efficient photonic waveguide and a highly miniaturized gas cell was pioneered by Mizaikoff and colleagues.²⁶ So-called substrate-integrated hollow waveguides (iHWGs) integrate photon guidance and gas cell, and enable analyzing exceedingly small gas sample volumes with excellent signal-to-noise ratio.^{26–28}

The scope of the present study was the demonstration of the first ICLED-iHWG combination, which provides a perspective on a potentially miniaturized, cost-effective, small-volume gas sensor for carbon dioxide (CO_2) and methane (CH_4) based on ICLED light sources.

Material and methods

Experimental setup

The optical setup for gas sample flow-through measurements is illustrated schematically in Fig. 1. The system comprises a thermoelectrically cooled ICLED emitting at a central wavelength of 4.0 μm (2500 cm^{-1}) or 3.4 μm (2941 cm^{-1}), respectively (fabricated by nanoplus Nanosystems and Technologies GmbH, Gerbrunn, Germany) mounted on a TO66 socket (TO66 Heatsink Cube, nanoplus Nanosystems and Technologies GmbH, Germany). For convenience, a Fourier transform infrared spectrometer (FTIR) was used for signal read-out and for spectrally analyzing the radiation after passing through the iHWG focused onto an internal mercury cadmium telluride (MCT) detector cooled with liquid nitrogen (N_2). Once the signal characteristics are determined, a dedicated detector matching the footprint of the ICLED-iHWG assembly will be implemented in lieu of the FTIR.

IR radiation emitted by the ICLED (red line) was coupled into the interferometer of the FTIR spectrometer (Vertex 70, Bruker Optic GmbH, Ettlingen, Germany) and subsequently coupled into the iHWG located inside the sample chamber of the FTIR system. After propagating through the iHWG, MIR radiation at the distal end (orange line) was focused onto an MCT detector (InfraRed Associates Inc., Stuart, FL, USA) with an active detector element area of 4 mm^2 matching the iHWG channel dimensions.

The ICLEDs used in this study had a nine-stage structure grown *via* molecular beam epitaxy on low-doped GaSb with a $640\text{ }\mu\text{m}$ squared mesa. The flip-chip mounted device can reach a maximum cw output power up to 5.1 mW at room temperature with a driving current of 600 mA. Further information and characterization of the ICLED can be found elsewhere.²⁹ To operate the ICLED, the chip was mounted

Fig. 1 Schematic of the sensor setup (ICLED: interband cascade laser light emitting diode; aspheric lens; OAPM: off-axis parabolic mirror; iHWG: integrated hollow waveguide; MCT-detector: mercury cadmium telluride detector).

Fig. 3 ICLED spectral emission (black) superimposed with a) FTIR-recorded CO₂ absorption spectrum (red) and the 4.0 μm central wavelength ICLED (black) and b) FTIR-recorded CH₄ absorption spectrum (red) and the 3.4 μm central wavelength ICLED (black). The ICLED spectral emission spectrum was likewise analyzed via the FTIR and smoothed with the Savitzky–Golay filter for better illustration.

onto a compact ($5 \times 4.8 \times 5 \text{ cm}^3$, $L \times W \times H$) heat sink, which allows thermoelectric cooling. For driving current and temperature control, a laser diode controller (TLD001, Thorlabs GmbH, Dachau/Munich, Germany) was used together with a TEC controller (TTC001, Thorlabs GmbH, Dachau/Munich, Germany) to ensure stable driving current and temperature, respectively. The ICLED was operated with a driving current of 200 mA and set to an operating temperature of 25 °C for all measurements.

Measurements procedure

For the gas measurements, CO₂ (1.00% carbon dioxide in N₂, Westfalen AG, Münster, Germany) and CH₄ (1.00% methane in N₂, Westfalen AG, Münster, Germany) were used. To produce gas mixtures, a customized gas mixing system (GMS) based on mass flow controllers was used, which was developed in collaboration with Lawrence Livermore National Laboratory (LLNL; Livermore/CA, USA).

Before starting the IR experiments, the iHWG gas flow-through cell was purged for three minutes using N₂ gas (99.999% N₂, MTI IndustrieGase AG, Neu-Ulm, Germany) at a flow rate of 200 mL min⁻¹. After purging, the IR background spectra was recorded. In the next step, a defined gas mixture of N₂ and CO₂ or CH₄ for the respective ICLED was set at the gas mixing system and the flow-through cell was flushed with the specified sample concentration at a flow rate of 200 mL min⁻¹ for three minutes. In the conducted experiments the CO₂ and CH₄ concentrations ranged from 1000 to 10 000 ppm_v. In the following, three repeated sample measurements were initiated. After recording the IR spectra of the set analyte concentration, the GMS was turned to N₂ to restart the purging step, and then the measurement step was repeated with the next higher concentration resulting in a total of 30 data points per measurement series. Three independent series of measurements were performed to verify and reproduce the data.

IR data acquisition and evaluation

For the IR data acquisition and processing the OPUS 8.1 (Bruker Optik GmbH, Ettlingen, Germany) software package was used recording CO₂ and CH₄ in the spectral range of 3000 to 2000 cm⁻¹ and 4000 to 2600 cm⁻¹, respectively (spectral res. 2 cm⁻¹) using a Blackman–Harris three-term apodization function and averaging 256 scans. Baseline correction was performed in the region 2385–2280 cm⁻¹ for CO₂ and 3025–3005 cm⁻¹ for CH₄ using the Essential eFTIR spectroscopy software toolbox (Essential FTIR, Madison WI, USA).

The suitability of ICLEDs for the quantification of relevant gases was evaluated by establishing calibration functions, and calculating the limit of detection (LOD), and limit of quantification (LOQ = 3 × LOD) for CO₂ and CH₄. To determine the LOD and LOQ, the peak areas of the antisymmetric stretching mode of CO₂ at 2345 cm⁻¹, and the area of the CH stretching rovibrational mode of CH₄ at 3020 cm⁻¹ were integrated using the Essential eFTIR spectroscopy software.

Subsequently, a linear correlation between the integrated peak area and the concentration was established, and the confidence and the prediction interval were calculated according to the approach of Hubaux and Vos.³⁰

Substrate-integrated hollow waveguide

Fig. 2 shows the cross-sectional view of the iHWG (75 × 25 × 20 mm, $L \times W \times H$) used in this study. The iHWG was fabricated from aluminum substrates and provides an optical path length of 70 mm with a hollow channel cross-section of 4 × 4 mm². The cover substrate on top has two threaded ports that serve as gas inlets and outlets into the radiation and gas propagation channel. To achieve high surface reflectance, the iHWG surfaces were polished to a mirror-like finish using commercially available diamond polishing suspensions. The three individual parts of the iHWG were sealed together and bonded with epoxy to

Fig. 4 Comparison of three separately prepared concentration series for CO₂ – a)–c) and CH₄ – d)–f) – respectively evaluated using the asymmetric stretching mode of CO₂ at 2345 cm⁻¹ and the CH stretching rovibrational mode of CH₄ at 3020 cm⁻¹. Based on the integrated peak areas, linear trend (red), confidence interval (blue), prediction interval (green) and LOD as well as LOQ were calculated.

ensure a gas-tight interface. Finally, to obtain a miniaturized gas cell, both ends were sealed gas-tight with MIR-transparent BaF₂ windows and epoxy, thus creating a highly miniaturized gas cell with a volume of 1120 μL. Details on iHWG technology can be found elsewhere.^{31–34}

Results and discussion

Verifying a suitable spectral overlap between the spectral emission of the ICLEDs and the characteristic absorption bands of CO₂ and CH₄, the emission spectra of the ICLEDs at

Table 1 Summary of SNR for CO₂ and CH₄ at 1000 ppm_v derived from the data shown in Fig. 4

	SNR
CO ₂	
(a)	14.2
(b)	11.6
(c)	13.0
CH ₄	
(d)	22.0
(e)	19.6
(f)	19.0

200 mA driving current were recorded using the FTIR spectrometer. The obtained spectra were smoothed with the Savitzky–Golay filter for better illustration, and then compared with the FTIR-recorded spectra of CO₂ and CH₄ using an iHWG. In Fig. 3 the IR spectra of the two ICLEDs radiation spectra (black) are superimposed onto the CO₂ and the CH₄ spectrum, respectively (red) clearly indicating the suitability of the ICLED emission for sensing CO₂ or CH₄.

Fig. 4 illustrates the integrated peak area of the antisymmetric stretching mode at 2345 cm⁻¹ of CO₂ and the CH stretching rovibrational mode of CH₄ at 3020 cm⁻¹ vs. the analyzed concentrations, respectively. The three independent measurement series for each analyte followed a linear trend with an *R*² value of >0.99 confirming the suitability of the established calibration model for quantitative analysis. To estimate the achievable LOD at the previously mentioned conditions, the suitability of ICLEDs was evaluated based on the calculated calibration functions. The resulting LODs were in the range of 386–407 ppm_v for CO₂, and of 302–338 ppm_v for CH₄. In addition, the obtained measurements were highly reproducible allowing the detection of small CO₂ and CH₄ sample volumes *via* the combination of ICLEDs with iHWGs.

To further characterize the performance of the sensor concept and the potential influence of stochastic and electronic noise, the signal-to-noise ratio (SNR) for the respective CO₂ and CH₄ measurements at 1000 ppm_v was derived.

Table 1 summarizes the SNRs for CO₂ – (a), (b), and (c) shown in Fig. 4, and for CH₄ – (d), (e), (f). SNRs of 11.6 to 14.2 for CO₂ and 19.0 to 22.0 for CH₄ were achieved, which is satisfactory considering that only a small portion of the IR light emitted by the ICLED led to the respective molecular transitions. The difference in SNR between the 4.0 μm ICLED and the 3.4 μm ICLED can be explained by the fact that CH₄ absorbs at the central emission wavelength of the 3.4 μm ICLED corresponding to the peak output power, while the CO₂ absorption is not located at the central emission wavelength of the 4.0 μm ICLED.

Comparing our results with recently published miniaturized gas sensor prototypes for CO₂ and CH₄ detection based on MIR LEDs,^{35–37} it was determined that the performance of the developed prototypes is at the same order of magnitude compared to the other CO₂ MIR LED sensor,³⁵ and CH₄ MIR LED sensors.^{36,37} Last but not least,

the performance of the ICLEDs operated in the present study in cw mode was comparable to MIR LEDs operated in previous studies using modulation techniques.

Conclusions

In this study, we demonstrated the first combination of two individual cw ICLEDs emitting at different central IR wavelengths as a low-cost and easy to operate MIR light source coupled with iHWGs serving simultaneously as waveguides and miniaturized gas cells for analyzing minute sample volumes of CO₂ and CH₄. The quantitative analysis of both gases showed a robust sensor behaviour with reproducible spectra for each analyte. Based on this analysis, the development of possibly integrated iHWG-ICLED-based sensors appears perfectly suitable for *e.g.*, sensing CO₂ concentrations in closed and open spaces, as well as the monitoring of the lower explosion limit of CH₄ in air with a performance on par with previously published MIR LED-based sensor types.

Future work will address further miniaturization of the optical setup by hybrid integration of the ICLED reflector and lenses together with the iHWG.

Already at this stage of development, the iHWG-ICLED combination has demonstrated that this type of sensor is suitable for the detection of relatively low concentrations of relevant gas phase constituents in the ppm_v range in minute sample volumes (*i.e.*, few hundreds of microliters). The modularity, flexibility and adaptability of the iHWG-ICLED combination can contribute significantly to the development of miniaturized and cost-effective gas sensors for a wide range of application scenarios in environmental analysis, process monitoring, and even biomedical diagnostics.
