Synthesis, biocompatibility, and antimicrobial properties of glucose-based ionic liquids

An effective and high-yielding synthesis of glucose-based imidazolium ionic liquids using a simple 2-step procedure was established. This approach easily enables the introduction of several substitutions on the carbohydrate and the imidazole. Thus, the tuneability of these novel substances, as well as higher cell viability and antimicrobial behaviour in comparison to common imidazolium-based ionic liquids were achieved. Paving the way to promising biocompatible ionic liquids of the third generation.

Synthesis, biocompatibility, and antimicrobial properties of glucose-based ionic liquids†

Stefan Jopp, ‡*[a] Tabea Fleischhammer, [b] Antonina Lavrentieva, [b] Selin Kara [b] and Johanna Meyer ‡*[b]

The diversity in structure, the variety in chirality, as well as the large occurrence of carbohydrates in nature, led to the development of the next generation of ionic liquids (ILs). These carbohydrate-based ionic liquids, also known as CHILs, are expected to overcome limitations such as aquatic ecotoxicity and poor biodegradability. In this work, we present the glucosyl imidazolium ILs, obtained *via* a simple two to three-step synthesis with total yields up to 90%. These compounds were obtained with several variations in alkyl- and aromatic side chains, glycosidic groups, anions, and protecting groups to study the influence of these variations on the biocompatibility and antimicrobial properties of the CHILs. The *in vitro* studies confirmed the biocompatibility of most of the CHILs for L929 mouse fibroblasts at 10^{-2} mol L^{-1}, a feat not achieved by commercial imidazolium ILs. We could confirm observed trends, like increased cytotoxicity with increasing alkyl chain length, as well as higher fluorinated anions. Additionally, some of the here reported novel CHILs had significantly higher IC_{50} values than comparable imidazolium, pyridinium, and pyrrolidinium-based ILs. Additionally, antibiotic resistance is an increasingly serious threat to global health. Consequently, the development of new substances with antibiotic properties is of high priority. The before-synthesized CHILs were investigated in their overall antimicrobial behavior towards a Gram-negative strain (*Escherichia coli* K-12), a Gram-positive strain (*Bacillus subtilis*), as well as a common yeast (*Candida auris* WT) *via* the disk diffusion test. The minimum inhibition concentration (MIC), minimum bactericidal concentration (MBC), and minimum fungicidal concentration (MFC) were determined from the active substances. Similar to the biocompatibility experiments, correlations can be found between the length of the alkyl chain, the non-polarity of the structure, as well as the amount of fluorine in the counterion. For *Candida auris*, GMIM-NTf_2 as well as GOIM-I show the strongest effect, with a MIC and MFC of 1 mmol L^{-1} and 5 mmol L^{-1}, respectively.

Sustainability spotlight

Ionic liquids (ILs) possess diverse and tuneable properties, enabling them for a diverse field of applications, such as organic synthesis, biocatalysis, as well as biomedical applications. Especially for biomedical applications, ILs need to exert low toxicity, which starkly contrasts the usually high toxicity, aquatic ecotoxicity, and poor biodegradability of classical ILs. The next generation of ILs overcomes this problem, containing more biocompatible cations and anions, originating from inexpensive raw materials such as amino acids or choline, which are known to be non-toxic. In this work, we present carbohydrate-based ILs from renewable resources (SDG 15). Additionally, most of these new materials had significantly better biocompatibility, compared to imidazolium, pyridinium, and pyrrolidinium-based ILs (SDG 6).

Introduction

Ionic liquids (ILs), defined as salts with a melting point below 100 °C, are a topic of broad interest due to their diverse and tunable properties as well as their wide field of applications.[1] These applications include organic synthesis,[2] biocatalysis,[3] electrochemistry,[4] extraction, and separation processes,[5] analytical chemistry,[6] as well as biomedical and pharmaceutical applications,[7] among many others. Especially for biomedical applications, ILs need to exert low toxicity, which starkly contrasts the usually high toxicity, aquatic ecotoxicity, and poor biodegradability of classical ILs based on imidazolium and pyridinium cations and fluorated anions such as triflate and bistriflylimide.[8,9] Additionally, the synthesis of these ILs of the first and second generation is neither cost-effective nor environmentally benign.[10] The third generation of ILs is ought to overcome these problems, and is defined differently by various sources. On the one hand, the third generation is described by

containing more biologically active ions, like pharmaceuticals or agrochemicals,[11] on the other hand the generation is stated to contain more biocompatible cations and anions, originating from inexpensive raw materials such as amino acids or choline, which are known to be non-toxic.[10,12] Another type of renewable resource that might be converted into ILs is carbohydrates. In recent years, these carbohydrate-based ionic liquids (CHILs)[13–15] have found several potential applications, like a positive influence on the rate and selectivity of Diels–Alder cycloadditions,[16] the possibility to adsorb metal cations like Pb^{2+} and Cd^{2+} from an aqueous solution,[17,18] as precursors for N-doped carbon materials[19] or as supported ionic liquid phase for the immobilized *Candida antarctica* lipase B biocatalyst (Novozym 435).[20]

Jopp *et al.* recently developed several synthetic processes to produce ILs based on carbohydrates such as riboses,[21] glucosamine,[22] and glucose,[20] and has furthermore proven remarkable biocompatibility of glucose and pentose-based pyridinium ILs.[23] However, many syntheses towards these CHILs include several reaction steps, including insertion and removal of protecting groups and inserting a leaving group to enable following quaternization with N-heterocycles or amines. This might be followed by an additional anion exchange. Thus, the synthesis of CHILs often suffers from low total yields due to the multi-step procedure. In some cases, even when only a straightforward three-step synthesis is employed, the total yields are still below 40–50%, due to the overall complexity of downstreaming when working with carbohydrates.[16]

This work expands on our group's recently developed synthetic procedure in which simple glucosyl imidazolium ILs have been prepared in a two to three-step synthesis with total yields of up to 90%.[20] These compounds will be synthesized to include several variations in alkyl- and aromatic side chains, varying glycosidic groups, different anions, and protecting groups to study the influence of these variations on the biocompatibility and antimicrobial properties of the CHILs.

According to the overall approved definition of biocompatibility published by Williams *et al.*, it is the ability of a material to perform with an appropriate host response in a specific application.[24] The selection of the suitable assay, international standard, or even the correct cell line should be well-considered. In most cases, the initial screening of biocompatibility is based on cell culture methods due to high sensitivity, reliability, and reproducibility, compared to other methods using algae and higher plants,[25] invertebrate animals,[26] vertebrate animals,[27] or even bacteria.[28] In this work, L929 mouse fibroblasts were used since this cell line is recommended by several biocompatibility regulation norms (*e.g.* DIN EN ISO 10993-1:2021-05). The mouse fibroblasts L929 are a reliable choice for materials and samples with skin contact, due to their important role in the wound healing process, for example around implants or drug delivery systems.[29]

Furthermore, we investigated the antimicrobial activity of these compounds with the disc diffusion method. The disk diffusion method, established by Bauer and Kirby *et al.*, is the gold standard for testing antimicrobial susceptibility and was performed according to the Clinical Laboratory Standard Institute (CLSI) – Performance Standards for Antimicrobial Disk Susceptibility Tests.[30,31] To obtain the minimum inhibition concentration (MIC) and minimum bactericidal concentration (MBC), the XTT assay was performed.

Experimental

Synthetic procedures and characterization data

The NMR spectra were recorded on a Bruker AVANCE 300 III or 500. $CDCl_3$ was calibrated as 7.27 (^{1}H) and 77.00 (^{13}C). DMSO-d_6 was calibrated as 2.49 (^{1}H) and 39.50 (^{13}C). D_2O was calibrated as 4.80 (^{1}H). ESI-MS was measured in an Agilent 1200/6210 Time-of-Flight LC-MS or a Thermo Scientific Exactive ESI/DART FTMS. The specific rotations were measured with a Dr Kernchen Gyromat-HP Digital Automatic Polarimeter with concentrations given in mg per mL. Thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) measurements were performed on a Setaram Labsys TGA-DSC 1600 with a heating program from 25 to 500 °C and a heating rate of 10 °C min^{-1} under an argon flow of 100 mL min^{-1}. Scanning electron microscopy (SEM) measurements were done using a JEM-ARM200F (JEOL), additional EDX investigations performed with the Dry SGD60 SDD-EDXS-Detector (JEOL). Acceleration voltage was between 10 and 20 kV. The silver content of the catalysts was measured by inductively coupled plasma optical emissions spectroscopy (ICP-OES) using the IRIS Intrepid II XPS device.

The chemicals *N*-ethylimidazole (>98%), *N*-butylimidazole (>98%), *N*-octyllimidazole (>98%), and *N*-benzylimidazole (>98%) have been supplied by TCI. *N*-Methylimidazole (99%) was supplied by Alfa Aesar. *N*-Vinylimidazole (99%), silver methanesulfonate (99%), methyl-α-D-glucopyranoside (99%), phenyl-β-D-glucopyranoside (98%), triphenylphosphine (99%), and imidazole (99%) were supplied by Thermo Scientific. *N*-Phenylimidazole (>98%) and octyl-β-D-glucopyranoside (99%) were supplied by Apollo Scientific. Iodine (99.5%) and silver bis-(trifluoromethanesulfonyl)-imide (96%) were supplied by Carbolution. *N*-Mesitylimidazole (purity not given) was supplied by ABCR. The solvents THF (99.9%) and ethyl acetate (99.7%) were supplied by Honeywell Riedel-de-Haën and the solvents chloroform (99.8%), methanol (99.8%) and DMF (99.5) were supplied by Fisher. Column chromatography was performed with silica gel (230–400 mesh particle size) supplied by Supelco.

General procedure for the synthesis of 6-iodo-glucopyranosides

Glucopyranoside **1a–d** (10 mmol), triphenylphosphine (15.5 mmol), iodine (14.5 mmol), and imidazole (20 mmol) were refluxed in THF (60 mL) for 4 h. The resulting solid was filtered off, the solvent was removed and the product was obtained after column chromatography.

Methyl-6-iodo-α-D-glucopyranoside 2a. White solid. 91% yield. Eluent for column chromatography: $CHCl_3$/MeOH 12 : 1.

T_m = 148–149 °C. $[\alpha]_D^{25}$ = +94.2 (c = 1.0, H_2O). ^{1}H-NMR (300 MHz, DMSO-d_6): δ = 2.87–2.95 (m, 1H); 3.16–3.27 (m, 3H); 3.31 (s, 3H, CH_3); 3.34–3.42 (m, 1H); 3.50–3.57 (m, 1H); 4.54 (d, 1H, ^3J = 3.65 Hz, H-1); 4.78 (d, 1H, ^3J = 6.43 Hz, OH); 4.86 (d, 1H, ^3J =

4.99 Hz, OH); 5.17 (d, 1H, ^3J = 5.83 Hz, OH). ^{13}C-NMR (75 MHz, DMSO-d_6): δ = 9.5 (C-6); 54.6 (CH_3); 70.9, 71.9, 72.7, 74.1 (C-2, C-3, C-4, C-5); 99.8 (C-1).

***n*-Octyl-6-iodo-β-D-glucopyranoside 2b.** White solid. 41% yield. Eluent for column chromatography: $CHCl_3$/MeOH 20 : 1 to 15 : 1.

T_m = 72–74 °C. $[\alpha]_D^{24}$ = −10.7 (c = 1.3, H_2O). ^{1}H-NMR (300 MHz, DMSO-d_6): δ = 0.82–0.87 (m, 3H, CH_3); 1.25–1.32 (m, 10H, 5CH_2); 1.48–1.55 (m, 2H, CH_2); 2.89–3.04 (m, 3H); 3.11–3.19 (m, 1H); 3.24 (dd, 1H, ^2J = 10.49 Hz, ^3J = 7.35 Hz, H-6a); 3.42–3.47 (m, 1H, OCH_{2a}); 3.51 (dd, 1H, ^2J = 10.53 Hz, ^3J = 2.26 Hz, H-6b); 3.69–3.77 (m, 1H, OCH_{2b}); 4.16 (d, 1H, ^3J = 7.83 Hz, H-1); 5.01 (t, 2H, ^3J = 4.96 Hz, OH); 5.18 (d, 1H, ^3J = 5.29 Hz, OH). ^{13}C-NMR (75 MHz, DMSO-d_6): δ = 9.1 (C-6); 13.9 (CH_3); 22.1, 25.5, 28.7, 28.8, 29.3, 31.3, 68.8 (CH_2); 73.4, 73.7, 74.7, 76.1 (C-2, C-3, C-4, C-5); 102.7 (C-1). HRMS (ESI, m/z): calculated for $C_{14}H_{27}IO_5^+Na^+$, 425.0801; measured 425.0805.

Phenyl-6-iodo-β-D-glucopyranoside 2c. Light-brown solid. 51% yield. Eluent for column chromatography: $CHCl_3$/MeOH 15 : 1.

T_m = 157–159 °C. $[\alpha]_D^{25}$ = −82.1 (c = 1.9, H_2O). ^{1}H-NMR (500 MHz, DMSO-d_6): δ = 3.02–3.06 (m, 1H); 3.24–3.35 (m, 4H); 3.56 (dd, 1H, ^2J = 10.39 Hz, ^3J = 1.90 Hz, H-6a); 4.93 (d, 1H, ^3J = 7.66 Hz, H-1); 5.18 (d, 1H, ^3J = 5.02 Hz, OH); 5.34 (d, 1H, ^3J = 5.42 Hz, OH); 5.37 (d, 1H, ^3J = 5.09 Hz, OH); 6.98–7.01 (m, 1H, H_{Ar}); 7.07–7.09 (m, 2H, H_{Ar}); 7.27–7.30 (m, 2H, H_{Ar}). ^{13}C-NMR (125 MHz, DMSO-d_6): δ = 8.5 (C-6); 73.3, 73.5, 75.0, 75.8 (C-2, C-3, C-4, C-5); 100.1 (C-1); 116.3, 121.9, 129.3 (CH_{Ar}); 157.2 (C_{Ar}). HRMS (ESI, m/z): calculated for $C_{12}H_{15}IO_5^+$, 365.9959; measured 365.9956.

Methyl-6-iodo-2,3,4-*O*-methyl-α-D-glucopyranoside 2d. Colorless liquid. 89% yield. Eluent for column chromatography: heptane/ethyl acetate 7 : 1 to 4 : 1.

$[\alpha]_D^{27}$ = +142.5 (c = 2.7, $CHCl_3$). ^{1}H-NMR (300 MHz, $CDCl_3$): δ = 2.94–3.00 (m, 1H); 3.20 (dd, 1H, ^3J = 9.62 Hz, ^3J = 3.62 Hz, H-2); 3.29–3.39 (m, 2H); 3.46 (s, 3H, CH_3); 3.50–3.56 (m, 2H); 3.52 (s, 3H, CH_3); 3.61 (s, 3H, CH_3); 3.62 (s, 3H, CH_3); 4.82 (d, 1H, ^3J = 3.62 Hz, H-1). ^{13}C-NMR (75 MHz, $CDCl_3$): δ = 7.5 (C-6); 55.5, 59.0, 60.8, 60.9 (CH_3); 69.3, 81.8, 83.1, 83.4 (C-2, C-3, C-4, C-5); 97.5 (C-1). HRMS (ESI, m/z): calculated for $C_{10}H_{19}IO_5^+Na^+$, 369.0169; measured 369.0175.

General procedure for the quarternization with imidazoles

6-Iodo-glucopyranoside **2a–d** (3 mmol) and the *N*-substituted imidazole (5 mmol) were dissolved in DMF (5 mL) and stirred at 110 °C for 20 hours. After cooling down, ethyl acetate (40 mL) was added and the flask was stored in a fridge overnight. The solvent was decanted and the precipitated solid or oil was repeatedly washed with ethyl acetate and dried under a high vacuum to achieve the product.

1-(Methyl-α-D-glucopyranosid-6-yl)-3-methylimidazolium iodide (GMIM-I) 3a. Reaction performed with **2a** and *N*-methylimidazole. Light-brown solid. 99% yield.

T_m = 172–173 °C. T_d = 246 °C. $[\alpha]_D^{25}$ = +63.4 (c = 1.8, H_2O). ^{1}H-NMR (300 MHz, D_2O): δ = 3.26–3.32 (m, 1H); 3.31 (s, 3H, OCH_3); 3.63 (dd, 1H, ^3J = 9.77 Hz, ^3J = 3.76 Hz, H-2); 3.72–3.78 (m, 1H); 3.94–3.98 (m, 1H); 4.00 (s, 3H, NCH_3); 4.50 (dd, 1H, ^2J = 14.60 Hz, ^3J = 7.30 Hz, H-6a); 4.69 (dd, 1H, ^2J = 14.60 Hz, ^3J = 2.54 Hz, H-6b); 4.89 (d, 1H, ^3J = 3.74 Hz, H-1); 7.55 (d, 1H, ^3J = 1.95 Hz, H_{Ar}); 7.64 (d, 1H, ^3J = 1.95 Hz, H_{Ar}); 8.89 (s, 1H, H_{Ar}). ^{13}C-NMR (75 MHz, D_2O): δ = 36.1 (NCH_3); 49.9 (C-6); 55.2 (OCH_3); 69.4, 70.5, 71.0, 72.9 (C-2, C-3, C-4, C-5); 99.3 (C-1); 123.2, 123.6, 137.0 (CH_{Ar}). HRMS (ESI, m/z): calculated for $C_{11}H_{19}N_2O_5^+$, 259.1294; measured 259.1299. Calculated for I^-, 126.9040; measured 126.9045.

1-(Methyl-α-D-glucopyranosid-6-yl)-3-ethylimidazolium iodide (GEIM-I) 3b. Reaction performed with **2a** and *N*-ethylimidazole. Off-white solid. 91% yield.

T_m = 99–101 °C. T_d = 248 °C. $[\alpha]_D^{26}$ = +46.5 (c = 1.5, H_2O). ^{1}H-NMR (500 MHz, D_2O): δ = 1.53 (t, 3H, ^3J = 7.37 Hz, CH_3); 3.22–3.26 (m, 1H); 3.25 (s, 3H, OCH_3); 3.57 (dd, 1H, ^3J = 9.78 Hz, ^3J = 3.83 Hz, H-2); 3.68–3.71 (m, 1H); 3.92 (ddd, 1H, ^3J = 10.05 Hz, ^3J = 7.66 Hz, ^3J = 2.44 Hz, H-5); 4.29 (q, 2H, ^3J = 7.37 Hz, NCH_2); 4.44 (dd, 1H, ^2J = 14.60 Hz, ^3J = 7.64 Hz, H-6a); 4.64 (dd, 1H, ^2J = 14.59 Hz, ^3J = 2.46 Hz, H-6b); 4.84 (d, 1H, ^3J = 3.81 Hz, H-1); 7.57–7.60 (m, 2H, H_{Ar}); 8.90 (s, 1H, H_{Ar}). ^{13}C-NMR (125 MHz, D_2O): δ = 14.5 (CH_3); 45.0 (NCH_2); 49.9 (C-6); 55.0 (OCH_3); 69.4, 70.5, 71.0, 72.9 (C-2, C-3, C-4, C-5); 99.3 (C-1); 122.0, 123.2, 136.0 (CH_{Ar}). HRMS (ESI, m/z): calculated for $C_{12}H_{21}N_2O_5^+$, 273.1455; measured 273.1461. Calculated for I^-, 126.9040; measured 126.9047.

1-(Methyl-α-D-glucopyranosid-6-yl)-3-vinylimidazolium iodide (GVIM-I) 3c. Reaction performed with **2a** and *N*-vinylimidazole with a temperature of 95 °C for 24 h. Light-brown solid. 73% yield.

T_m = 185 °C. General procedure for the anion exchange *via* silver iodide precipitation

The silver salt silver methanesulfonate or silver bis-(trifluoromethanesulfonyl)-imide (1 mmol) and **3a** (1 mmol) were suspended in water (5 mL) and stirred for 20 h under absence of light. The product was obtained after filtration and removal of water. In some cases, black particles will form in the product after its storage under light. A further dissolution in methanol, filtration and drying leads to the full removal of these remaining silver particles.

1-(Methyl-α-D-glucopyranosid-6-yl)-3-methylimidazolium methanesulfonate (GMIM-OMs) 4a. Reaction performed with silver methanesulfonate. Yellow solid. 99% yield.

T_m = 36–38 °C. T_d = 244 °C. $[\alpha]_D^{25}$ = +76.7 (c = 1.3, H_2O). ^{1}H-NMR (300 MHz, D_2O): δ = 2.84 (s, 3H, CH_3); 3.22 (dd, 1H, ^3J = 9.95 Hz, ^3J = 9.05 Hz); 3.27 (s, 3H, OCH_3); 3.56 (dd, 1H, ^3J = 9.78 Hz, ^3J = 3.79 Hz, H-2); 3.67–3.73 (m, 1H); 3.89–3.93 (m, 1H); 3.95 (s, 3H, NCH_3); 4.45 (dd, 1H, ^2J = 14.60 Hz, ^3J = 7.35 Hz, H-6a); 4.64 (dd, 1H, ^2J = 14.60 Hz, ^3J = 2.51 Hz, H-6b); 4.84 (d, 1H, ^3J = 3.77 Hz, H-1); 7.50–7.51 (m, 1H, H_{Ar}); 7.59–7.60 (m, 1H, H_{Ar}); 8.83 (s, 1H, H_{Ar}). ^{13}C-NMR (75 MHz, D_2O): δ = 35.8 (NCH_3); 38.4 (CH_3); 49.8 (C-6); 55.0 (OCH_3); 69.4, 70.4, 71.0, 72.9 (C-2, C-3, C-4, C-5); 99.3 (C-1); 123.2, 123.5, 137.0 (CH_{Ar}). 1-(Methyl-α-D-glucopyranosid-6-yl)-3-methylimidazolium bis-(trifluoromethanesulfonyl)-imide (GMIM-NTf$_2$) 4b. Reaction performed with silver bis-(trifluoromethanesulfonyl)-imide. Yellow liquid. 99% yield.

T_d = 250 °C. $[\alpha]_D^{25}$ = +55.8 (c = 2.1, H_2O). ^{1}H-NMR (300 MHz, D_2O): δ = 3.23 (dd, 1H, ^3J = 10.01 Hz, ^3J = 8.97 Hz); 3.27 (s, 3H, OCH_3); 3.57 (dd, 1H, ^3J = 9.78 Hz, ^3J = 3.80 Hz, H-2); 3.67–3.74 (m, 1H); 3.89–3.93 (m, 1H); 3.95 (s, 3H, NCH_3); 4.45 (dd, 1H, ^2J = 14.61 Hz, ^3J = 7.36 Hz, H-6a); 4.64 (dd, 1H, ^2J = 14.60 Hz, ^2J = 2.55 Hz, H-6b); 4.84 (d, 1H, ^3J = 3.78 Hz, H-1); 7.50–7.51 (m, 1H, H_{Ar}); 7.59–7.60 (m, 1H, H_{Ar}); 8.82 (s, 1H, H_{Ar}). ^{13}C-NMR (75 MHz, D_2O): δ = 35.7 (NCH_3); 49.8 (C-6); 55.0 (OCH_3); 69.4, 70.5, 71.0, 72.9 (C-2, C-3, C-4, C-5); 99.3 (C-1); 119.2 (q, ^1J = 319.8 Hz, CF_3); 123.2, 123.5, 136.9 (CH_{Ar}). ^{19}F-NMR (282 MHz, D_2O): δ = −79.2. HRMS (ESI, *m*/*z*): calculated for $C_{11}H_{19}N_2O_5^+$, 259.1294; measured 259.1293. Calculated for $C_2F_6NO_4S_2^-$, 279.9168; measured 279.9174.

In vitro biocompatibility

Cell line and culture conditions. The method was adapted from Winkler *et al.*[32] and Lavrentieva *et al.*,[33] in short: L929 murine (*Mus musculus*) fibroblasts (L-929, DMSZ No. ACC2) were purchased from Cell Line Service GmbH (Eppelheim, Germany) and routinely cultivated in 175 cm^2 cell culture flasks (Sarstedt AG and Co. KG, Nümbrecht, Germany) in Dulbecco's Modified Eagle's Medium (DMEM; Sigma-Aldrich Chemie GmbH, Steinheim, Germany), supplemented with 10% fetal calf serum (Sigma Aldrich Chemie GmbH, Steinheim, Germany) as well as 100 U mL^{-1} of penicillin and 100 μg mL^{-1} of streptomycin (penicillin–streptomycin antibiotic solution; Sigma-Aldrich Chemie GmbH, Steinheim, Germany) in a 5% CO_2 and humidified atmosphere at 37 °C (Heracell 240 incubator, Thermo Fisher Scientific Inc., Waltham, USA). Cells were subcultivated at 70–85% confluency by trypsin/EDTA solution (Sigma Aldrich Chemie GmbH, Steinheim, Germany) treatment after a washing step with phosphate-buffered saline (PBS; Thermo Fisher Scientific Inc., Waltham, USA). Experiments were performed with cells of passage numbers below 15. 24 h prior to the start of an experiment, cells were seeded in 96 well plates (Sarstedt AG and Co. KG, Nümbrecht, Germany) at a density of 8000 cells per well in 200 μL cell culture medium.

Preparation of CHILs-containing cell culture medium. For each investigated substance, a 1 × 10^{-1} mol L^{-1} stock solution was prepared. For this, the weighed CHILs were pre-sterilized in a UV chamber, dissolved in DMEM, and sterile-filtered. The stock solutions were diluted to the following concentrations: 1 × 10^{-2} mol L^{-1}, 1 × 10^{-3} mol L^{-1}, 1 × 10^{-4} mol L^{-1} and 1 × 10^{-5} mol L^{-1}.

CellTiter blue (CTB) viability assay. The cell viability of the L929 cells was determined by CellTiterBlue® cell viability assay (Promega GmbH, Mannheim, Germany) using cell-free controls for background fluorescence correction and untreated cell controls as per the manufacturer's instruction manual. In metabolically active cells, blue resazurin is reduced to purple fluorescent active resorufin. The resulting fluorescence intensity is correlated with the number of viable cells. The resorufin formation was monitored using a fluorescence plate reader (Fluoroskan Ascent, Thermo Fisher Scientific Inc., Waltham, MA, USA) at an excitation wavelength of 544 nm and an emission wavelength 590 nm. L929 cells were cultured in cell culture medium or cell culture medium with varying concentrations of CHILs for 48 h (8000 cells per well). Afterwards, the medium was carefully removed, 200 μL of serum-free cell culture medium containing 10% CTB stock solution was added to each well and the cells were incubated until the fluorescence of the control, which was measured in a plate reader, was in the range of 100–400 relative fluorescence units (rfu). Three biological replicates with six technical replicates each were analyzed.

Microscopic analysis. Microscopic imaging of the cells was performed using an IncuCyte S3 Live-Cell Analysis Instrument (Sartorius AG, Göttingen, Germany) before and after 48 h treatment of with the CHILs samples. Imaging was performed in the phase contrast channel using the intrinsic auto-exposure function of the IncuCyte software (Sartorius AG, Göttingen, Germany) with the 20× objective.

Live/dead staining of cells. For live/dead staining, the cells were treated for 48 h with the different substance concentrations already described above. After carefully removing the

medium from the incubated cells, 100 μL of cell culture medium containing 5 μM Calcein-AM (SigmaAldrich Chemie GmbH, München, Deutschland) and 0.125 μg mL^{-1} propidium iodide (SigmaAldrich Corporation, St. Louis, MO, USA) was added to each well. After the incubation at 37 °C for 15 min, the samples were analyzed with the BioTek Cytation 5 Cell Imaging Multi-Mode Reader (Agilent, Santa Clara, CA, USA). Imaging was performed in brightfield using the intrinsic auto-exposure function of the Gen5 imaging software (Version 3.10.06, BioTek Instruments GmbH, Bad Friedrichshall, Germany) with a 4× objective. For the detection of dead cells in the red channel dyed with propidium iodide, the Texas Red filter cube (Excitation: 586/15 nm; Emission: 647/57 nm) was used and for detection of calcein-dyed, viable cells, the GFP filter cube (excitation: 469/35 nm, emission: 525/39 nm) was used. Exposition parameters for the propidium iodide dye detection: LED intensity = 10, integration time = 1.88 s, gain = 11. Exposition parameters for the calcein dye detection: LED intensity = 5, integration time = 58 ms, gain = 0.

Antimicrobial activity testing

Disc diffusion method. The tests were performed against some of the most common strains for infections, *Escherichia coli* K-12, *Bacillus subtilis*, and *Candida auris* (WT). The species were stored as glycerol cultures with 20% v/v glycerol at −80 °C. For preculture, the LB medium, prepared from the recipe of Miller (5 g yeast extract, 10 g peptone, and 10 g NaCl in 1 L ultrapure water), was adjusted pH to 7.0, sterilized by autoclaving, and 10 g L^{-1} glucose were added after autoclaving. The cultivation of the bacteria and the yeast was conducted in 150 mL shake flasks with baffles at 150 rpm. After the inoculation, the strains were precultured overnight at 35 °C ± 2 °C before use.

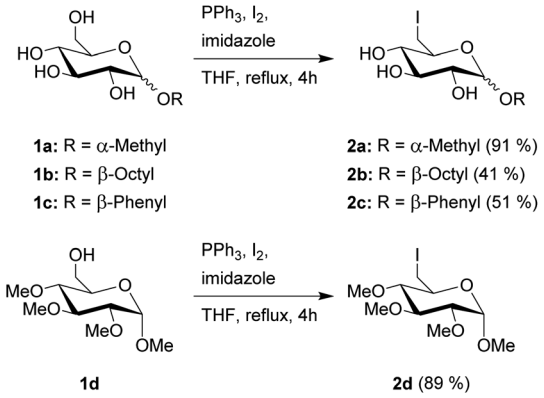
The examinations were performed in Mueller–Hinton agar (for fungal cultures 2% v/v glucose was added), prepared according to the manufacturer's instructions, and poured into 100 mm plates. The obtained bacteria solutions were adjusted for each organism to 1–2 × 10^7 CFU mL^{-1} (0.5 McFarland Standard, OD_{600} ≈ 0.120) and poured over the whole Mueller Hinton agar plate, using a sterilized bacteria solution-soaked cotton swab. 10 μL of the test solutions (10^{-1} mol L^{-1} in ultrapure H_2O) were transferred to the Whatman No. 1 filter paper discs (6 mm in diameter) and placed with sterile forceps on the agar plates after the H_2O was evaporated. As negative controls served filter paper discs with H_2O only, and the positive controls were Gentamicin (Roti®Antibiotic Discs Gentamicin (GEN) 10 μg, 6 mm, 50 Units, Carl Roth, Karlsruhe, Germany) for the bacterial strains and Amphotericin B (Roti®Antibiotic Discs Amphotericin B (AP) 100 Units, Carl Roth, Karlsruhe, Germany) for the yeast. The bacteria agar plates were incubated for 18 h, and the yeast agar plates were incubated for 24 h at 35 °C ± 2 °C and the zones of inhibition (ZOI, diameter) were measured in mm.

Minimum inhibition concentration (MIC), minimum bactericidal concentration (MBC), and minimum fungicidal concentration (MFC) determination. The MIC values of the CHILs and ILs were determined in quadruplets by the broth microdilution method in a 96-well microtiter plate using Mueller–Hinton Broth, adapted from the methodology from CLSI.[31] The test organisms were grown individually in Mueller–Hinton broth for 24 h at 35 °C ± 2 °C prior to each antibacterial test (for fungal cultures 2% v/v glucose was added). Each inoculum density was adjusted in Mueller–Hinton broth to 1–2 × 10^7 CFU mL^{-1} (0.5 McFarland Standard, OD_{600} ≈ 0.120). Subsequently, 100 μL of the suspension was added to each well to obtain 0.5–2.5 × 10^4 CFU mL^{-1} as a final concentration. The bacteria were exposed to 100 μL aqueous CHIL solutions in the following concentrations: 125 mmol L^{-1}, 100 mmol L^{-1}, 75 mmol L^{-1}, 50 mmol L^{-1}, 37.5 mmol L^{-1}, 25 mmol L^{-1}, 12.5 mmol L^{-1}, 10 mmol L^{-1}, 5 mmol L^{-1}, 2.5 mmol L^{-1}, 1 mmol L^{-1}, 1 × 10^{-1} mmol L^{-1}, 1 × 10^{-2} mmol L^{-1}, 1 × 10^{-3} mmol L^{-1}, 1 × 10^{-4} mmol L^{-1} and 1 × 10^{-5} mmol L^{-1}. The MIC for each CHIL was recorded as the lowest concentration that showed no turbidity after 24 h of incubation at 35 °C ± 2 °C. The presence of turbidity is an indication of microbial growth and the corresponding concentration of antibacterial agent is considered ineffective. To determine whether the CHIL inhibited growth or has bactericidal activity, 50 μL of aqueous XTT sodium salt solution (2,3-bis(2-methoxy-4-nitro-5-sulfophenyl)-5- [(phenylamino) carbonyl]-2*H*-tetrazolium, monosodium salt, hydrate, 0.6 mg mL^{-1}), containing menadione as an electron coupling reagent (0.1 mg mL^{-1}), was added to the non-turbid wells of the MIC assay plates and incubated for 2–20 h at 35 °C ± 2 °C, and measured in the photometer at a wavelength of 450–500 nm. In the case of viable microbes with inhibited growth, dehydrogenases of viable microbes cleave the tetrazolium ring of XTT yielding dark orange to red aqueous soluble formazan crystals. A solution containing only non-viable microbes would remain the same colour (light orange). In this case, MICs values were equal to MBC or MFC for each CHIL, so the antibacterial activities of these compounds were considered to be bactericidal.

Results

Synthesis of CHILs

The first step in the synthesis of the glucosylimidazolium ILs is an Appel reaction of the glucopyranosides **1a–d** (Scheme 1). This reaction enables the direct conversion of a hydroxy group into a halogen, which will function as a leaving group for the following quarternization. Due to the higher reactivity in both this step as well as the following quarternization, we chose to work with iodine. Furthermore, the reaction has a very high selectivity towards the primary hydroxy group in the C-6 position of the carbohydrate. These advantages of the Appel reaction are a key component in this overall strategy, as they allow us to skip several steps of protecting group chemistry prior to the introduction of the leaving group, leading to overall fewer steps and higher total yields. Starting materials **1a–c** are commercially available and the synthesis of starting material **1d** has been previously described by Jopp *et al.*[23] Interestingly, while the reaction protocol leads to yields of 91% and 89%, respectively, for the protected and unprotected α-methyl-glycosides **2a** and **2d**, both β-glycosides **2b** and **2c** were achieved in

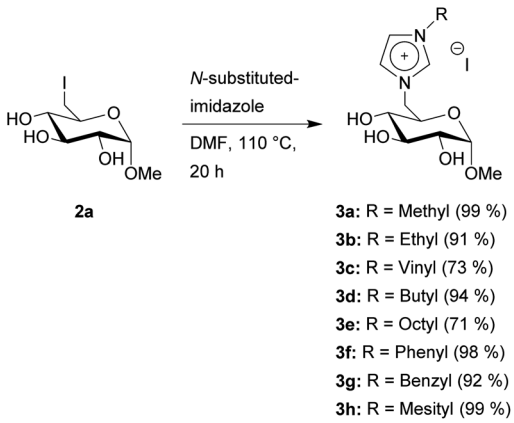


Scheme 1 Synthesis of 6-iodo-glucopyranosides **2a–d**.

significantly lower yields of 41 and 51%, respectively. These reactions had remaining starting material; however, an extension of the reaction time from 4 to 20 hours did not increase the yields. Furthermore, the reaction with β-methylglucopyranoside as starting material leads to no product formation, leading us to conclude that the β-anomers are generally less reactive for this kind of Appel reaction.

Next, we converted **2a** into the CHILs **3a–h.** This reaction is performed with varying *N*-substituted imidazoles in DMF (Scheme 2). After the reaction, most of the products can be obtained through precipitation after the addition of ethyl acetate to the reaction mixture. Only **3g** needs a short column chromatography using ethyl acetate and methanol for purification since *N*-benzylimidazole is not sufficiently removable through washing after precipitation of **3g** from ethyl acetate.

Most of the products are obtained with yields of ≥90%. The vinyl product **3c** needs a lowered reaction temperature of 95 °C, otherwise, the product will turn from a light-brown solid to a dark-brown oil, with no visible change in the NMR data however. This lowered reaction temperature also leads to a lower yield of 73%. The octyl-substituted product **3e** was obtained in a yield of 71% due to the partial solubility of **3e** in ethyl acetate, which was used for precipitation as described before.

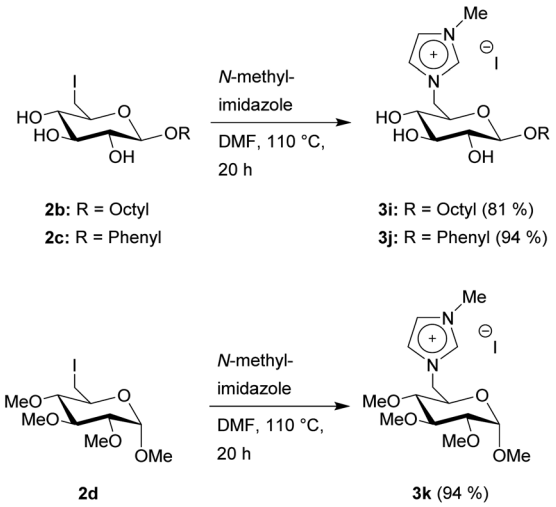


Scheme 2 Synthesis of glucosyl imidazolium CHILs with varying side chains on the imidazole.

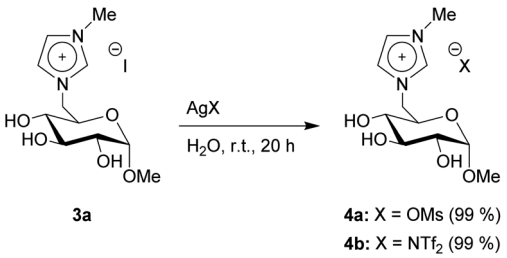
To achieve two products directly comparable to **3a,** but with different glycosidic groups, we converted **2b** and **2c** with *N*-methylimidazole to **3i–j** (Scheme 3). Furthermore, the permethylated **2d** was also converted with *N*-methylimidazole to **3k.** These three products were synthesized and purified in the same manner as before and obtained with yields ranging from 81 to 94%.

As the last synthetic step, we produced two additional products through anion exchange. **3a** and a silver salt were suspended in water, leading to the precipitation of silver iodide. The products **4a–b** bearing a mesylate (OMs) and a bistriflylimide (NTf_2) anion were both achieved in full conversion (Scheme 4). The full removal of the silver particles, which are formed during the anion exchange, was confirmed by SEM-EDX and ICP-OES measurements (Fig. S37 to S60†).

Since our novel ionic liquids are produced from natural resources and aimed to achieve a high biocompatibility, we were also interested to optimize our reactions to be as green as possible. For this, we performed a First Pass Green Chemistry Metrics test as published by Clark *et al.* for the two-step synthesis of GMIM-I **3a**.[34] In this toolkit, each reaction is given green, amber or red flags for several parameters such as yield and selectivity, but also for the toxicity of the used solvents or reagents, the use of catalysts and much more. Unsurprisingly, the first reaction from **1a** to **2a** fails this test in many parameters. The Appel reaction uses an excess of reagents, which leads to a low atom economy, was performed under reflux and was worked up by column chromatography with the highly hazardous chloroform, all of which are red flags. The reaction however has a high yield and high selectivity, which are major green flags. We made many efforts to address these red flag concerns. In case of the work-up with column chromatography, no other mixtures of ethyl acetate, acetonitrile or methanol were able to achieve a good separation on TLC. We also tried to move away from the column chromatography in general. We found that in case of product **2a**, the extraction of an aqueous reaction



Scheme 3 Synthesis of glucosylimidazolium CHILs with varying glycosidic groups and with permethylated hydroxy groups.



Scheme 4 Anion exchange reactions.

mixture with toluene leads to the full removal of triphenylphosphine(oxide), leaving only product **2a** and the remaining imidazole in the aqueous phase. This mixture however still needs a chloroform/methanol column chromatography.

Lastly, we tried to replace the imidazole with other bases like triethylamine and di-iso-propylethylamine or with other imidazoles like *N*-methyl-, *N*-butyl-, or *N*-benzylimidazole, which all might lead to an easier separation of **2a**. Unfortunately, this proved to be unsuccessful as well, with all of these bases leading to either no full conversion of **1a** or having no positive influence on the separation process. Finally, we also tried to perform the Appel reaction under catalytic conditions, as published by Werner *et al.* for organocatalytic chlorination, but this was also not possible for the carbohydrate starting material.[35] As such, this reaction can unfortunately not be performed in a greener way. Other pathways to the same product **2a** would most likely need multi-step reactions including the introduction and removal of protecting groups, as no known reaction is as selective as the Appel reaction. It should however be noted, as these points are not addressed in the green chemistry evaluation, that all side products can be fully removed from the reaction and would thus be available for other processes. Imidazolium hydroiodide is collected *via* filtration, and both the triphenylphoshine oxide and the remaining excess of imidazole can be fully separated by column chromatography without any mix phases.

On a more positive note, the second reaction from **2a** to GMIM-I **3a** passes the green chemistry evaluation in most of the parameters. This reaction has green flags for its nearly 100% yield as well as 100% selectivity and atom economy and an amber flag for the 87% reaction mass efficiency, since only a small excess of *N*-methylimidazole is used. The reaction is performed at medium–high temperatures (110 °C), which is an amber flag, but not under reflux, which is a green flag. The work-up is a filtration/washing with the green solvent ethyl acetate, which are again major green flags. Overall this reaction has only one concern, which is the red flag solvent DMF. This reaction however needs a highly polar solvent and a temperature of at least 110 °C, thus leaving not many alternatives. One less problematic solvent would be DMSO, however, the desirable work-up *via* filtration does not work from DMSO.

Thermal analysis of CHILs

Next, we performed the measurements of melting points (T_m) and decomposition temperatures (T_d) for **3a–k** and **4a–b** (Table 1). The comparison of the melting points of **3a** to **3h** gives insight into the effect of the different side chains on the imidazolium cation. The melting points fall with increasing alkyl chain length, with the methyl-substituted salt **3a** starting with a high melting point of 172–173 °C, the ethyl-substituted product **3b** already bordering the ionic liquid definition with 99–101 °C and both butyl- and octyl-substituted **3c–d** appearing as viscous liquids at room temperature. This follows the established trend for ionic liquids, in which bulky groups on either cation or anion lead to a lower ion interaction and thus to a lower melting point.[36] The β-octyl glycoside **3i** is a constitutional isomer of **3e**. However, whether the octyl chain is bound to the imidazolium cation (**3e**) or to the anomeric center (**3i**), in both cases the products are viscous liquids at room temperature.

In contrast, the β-phenyl glycoside **3j**, a constitutional isomer of **3f** (T_m = 50 °C), exhibits the highest melting point of all products at 195 °C. Lastly, the anion exchange from iodide **3a** to mesylate **4a** and bistriflylimide **4b** leads to a drastically lowered melting point. **4a** has a melting point of 36–38 °C and **4b** appears as a viscous liquid at room temperature. This again follows the established trends known for ionic liquids, in which sulfonate anions often have fewer interactions with the cations, thus reducing the melting point. While the melting points of all our CHILs allow the assessment of certain trends, all decomposition temperatures fall into the same range of around 240 to 250 °C, indifferent from the existing variations. This behavior has previously also been observed by our group for protected riboses[21] as well as for trimethylammonium-glucosamines.[37] Both, interestingly, fall into similar ranges with 230–250 °C and 240–260 °C, respectively. Thus, the overall thermal stability of these CHILs, including the aforementioned riboses and glucosamines, might be dictated by a function existing unchanged in all of these products, such as the anomeric center. Only one product exhibits a notably higher decomposition temperature: the permethylated glucosyl imidazolium product **3k**.

In vitro biocompatibility analyses of CHILs

L929 cells are standard for biocompatibility testing by the international organization for standardization and, therefore,

are commonly used. This work assessed the potential cytotoxicity of the CHILs to L929 cells using the CTB cell viability assay (Fig. 1) and live/dead staining with calcein-AM and propidium iodide (Fig. 2). As shown in Fig. 1, the CTB assay reveals that the CHILs, as well as the commercial ILs, are all cytotoxic at the highest tested concentration of 10^{-1} mol L^{-1}. The trend of increasing toxicity to L929 mouse fibroblasts with increasing hydrophobicity, corresponding to an increasing alkyl chain length of the substituted groups on the imidazolium rest was observed (Fig. 1A). Thus, those CHILs with longer alkyl chains on carbohydrate cations were more toxic. In addition, cell viability is significantly decreased for CHILS with longer alkyl chains even after reducing the concentration to 10^{-2} mol L^{-1}, which leads to the biocompatibility of most of the other substances. These two trends are also confirmed by the light microscopy images and the live/dead staining (Fig. 2). At the highest concentration of GMIM-I and GOIM-I, cells show a rounded morphology in both samples and a reduced growth compared to the control in the brightfield microscopy pictures, indicating that both compounds are cytotoxic at this concentration. However, the live/dead staining revealed a strong difference between the two substances. Whereas with GMIM-I some strongly rounded cells were stained with calcein-AM, there are no viable cells stained with the live stain at all with GOIM-I. The same correlation of chain lengths can also be observed in Fig. 1B. Longer chain lengths or generally a higher hydrophobicity, leads to lower cell viability. This can best be observed in the OctO-GMIM-I and GOIM-I data, as the cell viability similarly low in both cases. It can therefore be stated that the position of the alkyl chains is mostly insignificant.

Additionally, we investigated anion-dependant patterns in the new CHILs (Fig. 1C), as well as in the studied commercial ILs (Fig. 1D). The influence of GMIM-OMs and GMIM-NTf_2 to L929 fibroblasts lead to a lower cell viability than GMIM-I, which can already be considered biocompatible at a concentration of 10^{-2} mol L^{-1}. It can be concluded that the counterions increase the toxicity of the overall CHIL with greater non-polarity or are more fluorinated. With the common imidazolium-ILs as well as for the commercially available EMIM-I and EMIM-NTf_2 samples, the same trend can be observed. The HO-EMIM-I, which was synthesized in one of our previous works,[20] to show the influence of hydroxy groups, which are of course also present in the CHILs, was an interesting comparison. It already showed significantly higher cell viability, especially at a concentration of 10^{-2} mol L^{-1}. This

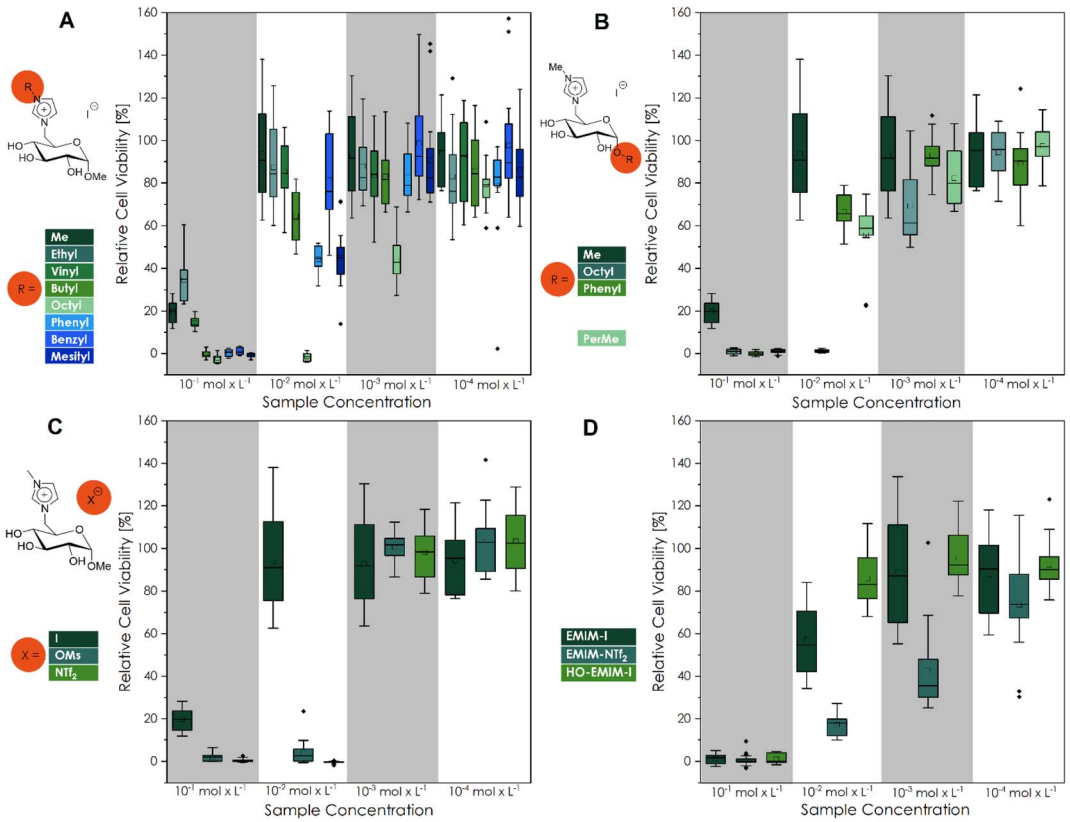

Fig. 1 Cell viability after cultivation for 48 h of L929 cells in different concentrated (10^{-1} mol L^{-1}; 10^{-2} mol L^{-1}; 10^{-3} mol L^{-1}; 10^{-4} mol L^{-1}) CHIL solutions ((A) different imidazolium substituents; (B) different substituents at the anomeric center; (C) different counter ions and (D) commercial IL samples). The mean value of the wells without cells (background fluorescence) was subtracted from the fluorescence values of the rest of the wells, and the values of treated cultures were normalized to the mean fluorescence of the control cultures. Three biological replicates with six technical replicates each were analyzed, except for OctO-GMIM-I (**3i**; 10^{-2} mol L^{-1}), PerMe-GMIM-I (**3k**; 10^{-2} mol L^{-1}), GMIM-NTf_2 (**4b**; 10^{-2} mol L^{-1}) and EMIM-I (10^{-3} mol L^{-1}). These four CHILs had one biological replication significantly different from the other two (Fig. S36 to S38†) and were defined as outliers. Every cell viability of each biological replicate is demonstrated in Fig. S36 to S38.†

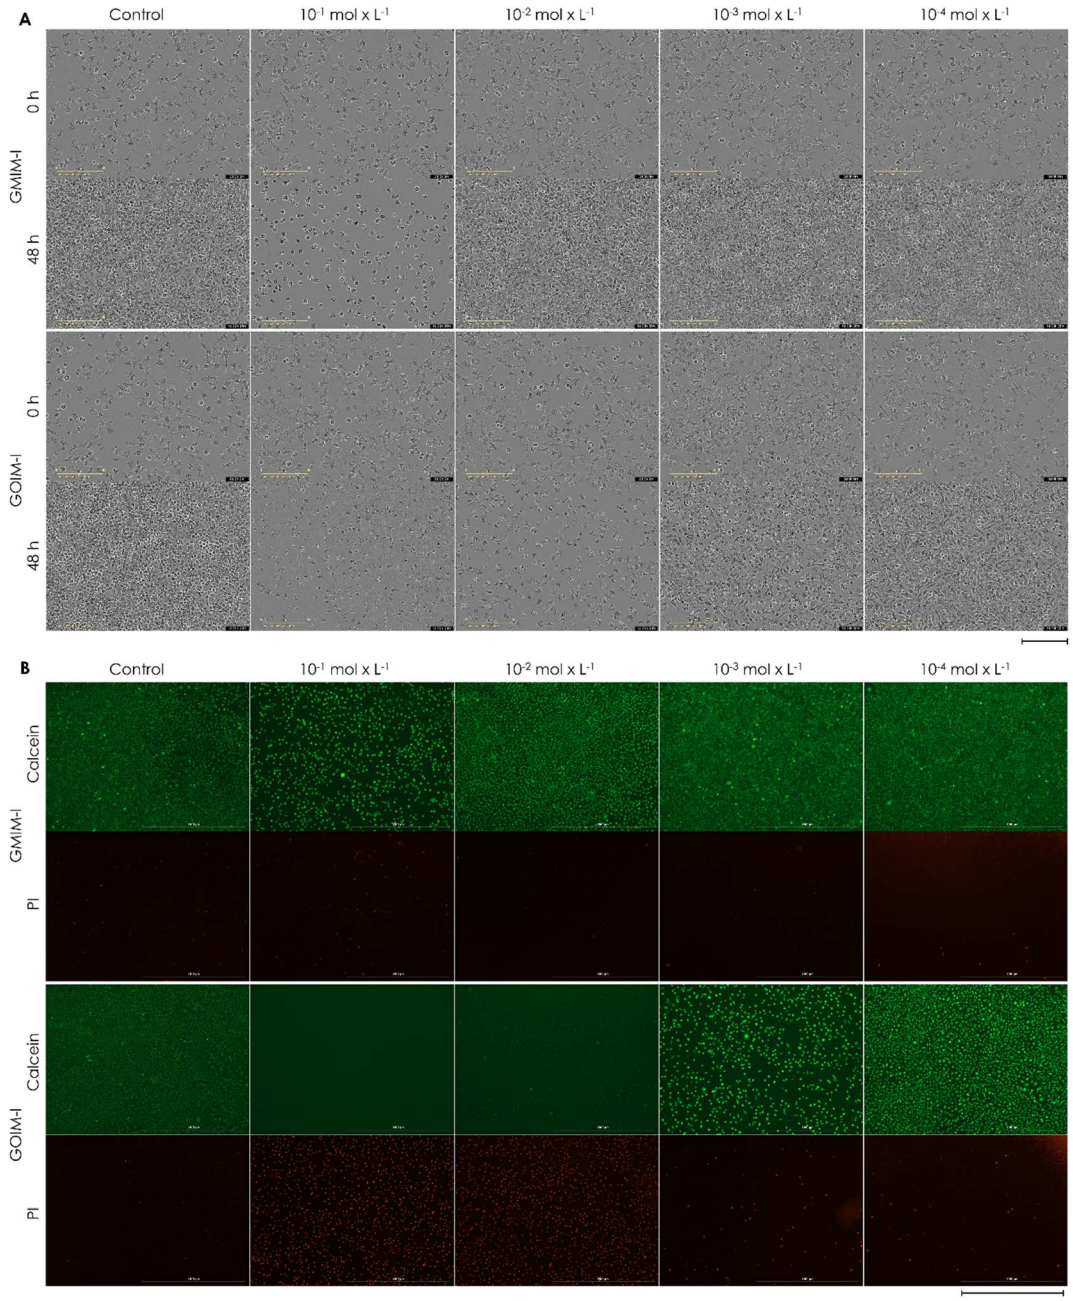

Fig. 2 (A) Microscopic images after 0 h and 48 h (scale bar 200 μm) and (B) calcein-AM/PI staining (scale bar 1000 μm) of L929 cells cultivated for 48 h in different concentrated (10^{-1} mol L^{-1}; 10^{-2} mol L^{-1}; 10^{-3} mol L^{-1}; 10^{-4} mol L^{-1}) CHIL solutions. One representative of each concentration of every CHIL is demonstrated in Fig. S39 to S48.†

could be due to the hydrophilic character of the structure. These findings could be confirmed by the calculated IC_{50} values (Fig. 3).

Antimicrobial activity

The initial antimicrobial screening of the new substances towards the Gram-positive strain *B. subtilis*, the Gram-negative strain *E. coli* K-12, as the yeast *C. auris* (WT) was carried out by disk diffusion assays (Fig. 4).

Antimicrobial susceptibility disks, loaded with 10 μL of 10^{-1} mol L^{-1} aqueous CHIL solution, showed a high sensitivity of several substances. The obtained zones of inhibitions (ZOI) are clearly related to the structure of the investigated CHIL samples.

Based on the results, a clear structure–property relationship could be obtained. For all organisms, the most nonpolar compounds, as well as the most fluorinated compounds, exhibited the most pronounced effect. In particular, the CHIL with the longest alkyl chain GOIM-I and the CHIL GMIM-NTf_2 with fluorinated anion showed the strongest effect on nearly all three organisms. In addition to the disc diffusion tests, broth microdilution experiments were performed to determine the respective MIC, as well as the MBC and MFC values (Table 2).

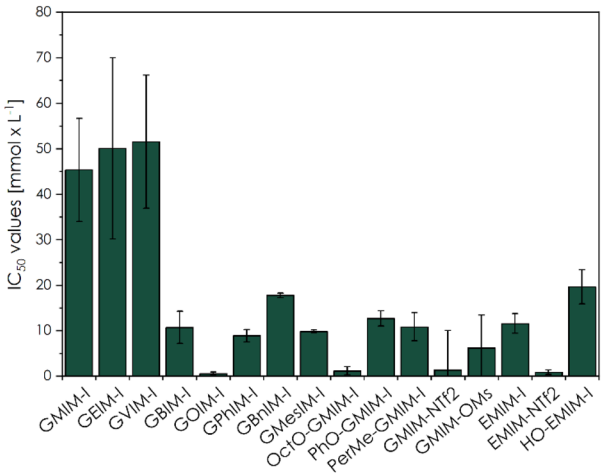

Fig. 3 Comparison of IC_{50} values for L929 mouse fibroblasts towards the investigated CHILs (13 entries from left) and commercial IL samples (last three entries) during a 48 h incubation (CellTiter-Blue fluorescence).

It can be concluded that the investigated substances show the most effect on *C. auris* compared to *E. coli* and *B. subtilis*. Similar to the biocompatibility experiments, correlations can be found between the length of the alkyl chain, the non-polarity of the structure, as well as the amount of fluorine in the counterion. In each organism, GMIM-NTf_2 as well as GOIM-I show the strongest effect.

Discussion

As the main investigations of this work, after the synthesis of the novel CHILs, in total, the 13 glucosyl imidazolium ILs as well as three additional commercial imidazolium ILs have been tested for their *in vitro* biocompatibility and antimicrobial properties. The biocompatibility tests, performed with L929 mouse fibroblasts, showed higher cell viability for most of the CHIL-treated samples than the commercial imidazolium ILs. At 10^{-2} mol L^{-1} most of the CHILs can be considered biocompatible, a feat not achieved by commercial imidazolium ILs. Additionally, the antimicrobial properties of the CHILs were investigated with the disk diffusion test. The glucosyl imidazolium ILs exhibited a stronger effect on the yeast *C. auris* compared to the Gram-negative and Gram-positive bacteria *E. coli* and *B. subtilis*. Here, the octyl-substituted CHIL was able to reach zones of inhibition higher than the control antibiotic.

Table 2 Minimum inhibitory concentration (MIC), minimum bactericidal concentration (MBC), and minimum fungicidal concentration (MFC) (expressed as mmol L^{-1}) of test antimicrobial combinations against representative strains determined by broth microdilution method ($n = 4$)

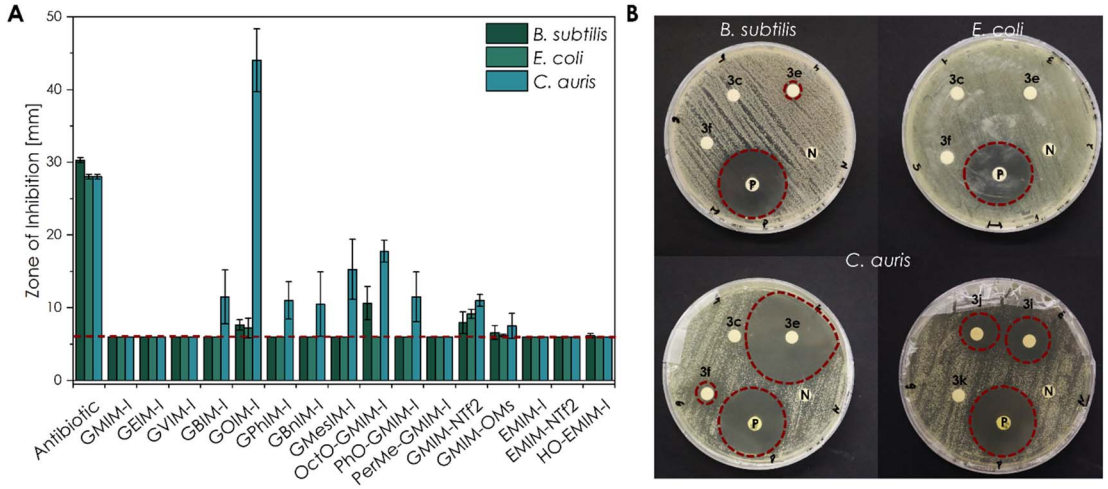

Fig. 4 Antimicrobial activity of different CHIL samples against *E. coli* K-12, *B. subtilis*, and *C. auris* (WT) obtained by the disk diffusion method (10 µL of an aqueous 10^{-1} mol L^{-1} solution). (A) The mean diameter of the ZOI (in mm, including the 6 mm diameter of the disc) of all CHILs performed in $n = 4$ experiments, error bars indicate + SD. The red dashed line indicates the size of the filter disk itself so that only a ZOI with a bigger size showed an antimicrobial effect. Only a ZOI above this line showed an antimicrobial effect. (B) Representative sample agar plates showing the ZOI formed by the CHILs and the antibiotics (illustrated by the red dashed line; **3c** GVIM-I; **3e** GOIM-I; **3f** GPhIM-I; **3i** OctO-GMIM-I; **3j** PhO-GMIM-I and **3k** PerMe-GMIM-I). Complete overviews of the disk diffusion tests are given in Fig. S49 to S51.†

We have furthermore defined trends, like increased cytotoxicity with increasing alkyl chain length. These correlations are in accordance with the data of ILs based on imidazolium from the literature.[38] Docherty *et al.* investigated the antibacterial behavior of 1-alkyl-3-methyl g-imidazolium ILs towards different alkyl chain lengths against *E. coli*, *S. aureus*, and *B. subtilis*. When the alkyl chain of 1-hexyl-3-methyl imidazolium bromide was extended to 1-octyl-3-methyl imidazolium bromide, the EC_{50} value increased from 1.17 ppm to 6.44 ppm.[39] The log EC_{50} values of Docherty *et al.* indicated a clear trend with 4.01 ± 0.05 μmol L^{-1} (BMIM-Br), 1.42 ± 0.05 μmol L^{-1} (HexMIM-Br), and 0.63 ± 0.05 μmol L^{-1} (OMIM-Br) with increasing chain length at the imidazolium cation against *Vibrio fischeri*.[39,40] As well as the LC_{50} values against *Artemia salina*, published by Gouveia *et al.*, with 0.092 ± 0.005 mmol L^{-1} (BuMIM-Br) and 0.079 ± 0.005 mmol L^{-1} (HexMIM-Br).[26]

According to the literature, the anions of ILs do not affect physical and chemical properties as much as the structure of the cation as well as the length of the alkyl side chain.[25,27,41] However, biocompatibility can still be influenced by anions. In this study, we verified the dependency between the cytotoxicity of the investigated compounds and the fluorination of the counter ion. This is already described with different organisms by Cho *et al.* They defined the influences of counterions on the growth of *Selenastrum capricornutum*, indicating a decreased toxicity in the following order: SbF_6^- > PF_6^- > BF_6^- > NTf_2^- > Ts^- > Br^- ≈ Cl^-.[25] This would indicate higher toxicity if the anions are fluorinated. Other tendencies differ immensely through the literature. While Biczak *et al.* investigated different EMIM IL concentrations in soil towards common radish, resulting in a clear trend of the anions: DMP^- (dimethyl phosphate) > OMs^- > Ts^- > NO_3^- > Br^-.[42] Rebros *et al.* could only find minor differences between OMs^- and I^- counterions on the different investigated imidazolium ILs.[43] In our biocompatibility experiments as well as antibacterial testings, we could observe similar patterns: NTf_2^- > OMs^- > I^-.

The calculated the IC_{50} values from the L929 mouse fibroblasts towards the CHIL samples reached from 0.55 ± 0.31 mmol L^{-1} to 51.50 ± 14.61 mmol L^{-1}, GOIM-I and GVIM-I, respectively. Compared to previously published CHILs by Reiß *et al.*, these were within the expected range.[23] When comparing the IC_{50} values of here described CHILs to other common ILs investigated by Dzida *et al.*, the typical imidazolium-based ILs were reported with IC_{50} values from 0.17 ± 0.02 mmol L^{-1} of 1-methyl-3-octylimidazolium trifluoromethanesulfonate (OMIM-TFO) to 30.50 ± 2.50 mmol L^{-1} of 1-ethyl-3-methylimidazolium dimethylphosphate (EMIMDMP).[44] These IC_{50} values are in the range of our samples, whereas the CHILs with shorter alkyl chains, such as GMIMI, GEIMI and GVIMI showed a significant higher value. The other by Dzida *et al.* reported IC_{50} values from pyridinium- and pyrrolidinium-based ILs to normal human dermal fibroblasts (NHDF) were even in lower ranges. Other more vaguely comparable studies, with EC_{50} values based on the decrease of light emission by *P. phosphoreum*, the reported values range from 0.70 ± 0.16 μmol L^{-1} (OMIM-PF_6) to 4.02 ± 0.14 μmol L^{-1} (EMIMESO_4).[40]

Conclusion

Synthetically this work features a total of 13 glucosyl imidazolium ILs, which have been prepared from commercially available glucosides in a straightforward two- or three-step synthesis with total yields up to 90%. Six of these CHILs have not been described in the literature before.

The melting points as well as the decomposition temperatures of these CHILs have been put in perspective to confirm certain trends, like the reduction of the melting point, from 172–173 °C with a methyl group (GMIM-I) to the viscous liquid of GOIM-I at room temperature, with increasing bulk of the alkyl- or aromatic side chain. On the other hand, the decomposition temperatures, ranging from 236 °C (GVIM-I) to 255 °C (GBnIM-I), of the glucosyl imidazolium ionic liquids change only slightly with structural variations, confirming a trend found through several works of our group, indicating that most likely the anomeric center is the main influence on the thermal stability of the CHILs.

We have observed trends, like increased cytotoxicity with increasing alkyl chain length (GMIM-I ≈ GEIM-I ≈ GVIM-I < GBnIM-I < GBuIM-I < GPhIM-I ≈ GMesIM-I < GOIM-I), as well as higher fluorinated anions (NTf_2^- > OMs^- > I^-). Even though the organisms in the literature described in the discussion, are mostly different in the literature, these tendencies we observed with the here-described new CHILs were confirmed and extended in our experiments. In future studies, the mechanism of these cytotoxicity trends with longer chain lengths will be studied.

Additionally, some of the here reported novel CHILs had significantly higher IC_{50} values, than comparable imidazolium-, pyridinium-, and pyrrolidinium-based ILs. GVIM-I, the CHIL with the highest IC_{50} value of 51.50 ± 14.61 mmol L^{-1}, showing a significantly higher biocompatibility compared to 0.17 ± 0.02 mmol L^{-1} of OMIM-TFO against *P. phosphoreum*, 0.392 mmol L^{-1} of 1-butylpyridinium chloride against *S. vacuolatus* or 2.43 mmol L^{-1} of 1-butyl-1-methylpyrrolidinium chloride against *S. vacuolatus*.[44,45] This could path the way to novel applications of these compounds, such as an environmentally friendly solvent or a polymerizable monomer for biomaterials.

Acknowledgements

SJ thanks the German Research Center (Deutsche Forschungsgemeinschaft, DFG) for the financial support (NFDI4-Cat; DFG grant no. 441926934). AL and TF thank the German Research Center (Deutsche Forschungsgemeinschaft, DFG) for the financial support (DFG grant no 398007461 488). SK and JM thank the Ministry for Science and Culture for Lower Saxony for the Holen & Halten starting grant (grant no. 12.5-76251-17-9/20). We also like to thank Martin Paehler, Martina Weiß, Caroline Mueller, Laura Schmitz from the Institute of Technical Chemistry TCI (Leibniz University Hannover), and Sandra Diederich from the Institute of Chemistry (University of Rostock) for their support on the day-to-day laboratory routine. Furthermore, we thank Sina Lambrecht from the Institute of Chemistry (University of Rostock), Tom Kunde and Riekje Biermann from the TCI (Leibniz University Hannover) for their assistance in the lab. Lastly, we thank Dr Carsten Kreyenschulte (Leibniz Institute for Catalysis, Rostock) and Dr Fanny Langschwager (Faculty of Mechanical Engineering and Marine Technologies, University of Rostock) for the measurements of SEM-EDX and ICP-OES, respectively.
