Recent advances in nanocomposite-based delivery systems for targeted CRISPR/Cas delivery and therapeutic genetic manipulation

Muhammad Waseem Ghani, ^{ab} Ambreen Iqbal, ^{ab} Hammad Ghani, ^c
Sidra Bibi, ^d Zixun Wang ^{*ab} and Renjun Pei ^{*ab}

CRISPR/Cas systems are novel gene editing tools with tremendous capacity and accuracy for gene editing and hold great potential for therapeutic genetic manipulation. However, the lack of safe and efficient delivery methods for CRISPR/Cas and its guide RNA hinders their wide adoption for therapeutic applications. To this end, there is an increasing demand for safe, efficient, precise, and non-pathogenic delivery approaches, both *in vitro* and *in vivo*. With the convergence of nanotechnology and biomedicine, functional nanocomposites have demonstrated unparalleled sophistication to overcome the limits of CRISPR/Cas delivery. The tunability of the physicochemical properties of nanocomposites makes it very easy to conjugate them with different functional substances. The combinatorial application of diverse functional materials in the form of nanocomposites has shown excellent properties for CRISPR/Cas delivery at the target site with therapeutic potential. The recent highlights of selective organ targeting and phase I clinical trials for gene manipulation by CRISPR/Cas after delivery through LNPs are at the brink of making it to routine clinical practice. Here we summarize the recent advances in delivering CRISPR/Cas systems through nanocomposites for targeted delivery and therapeutic genome editing.

rsc.li/materials-b10th Anniversary statement

Over the past ten years, the studies on all aspects of materials chemistry, from chemistry to applications in biology and medicine, have been published in the *Journal of Materials Chemistry B*, which has earned a stellar reputation as a premier venue for publishing such work. We are honored to have our work published in this 10th anniversary themed issue. I would like to take this opportunity to congratulate everyone involved in the *Journal of Materials Chemistry B* and to offer my best wishes for the journal's continued success in the years to come, as it celebrates its tenth anniversary.

1 Introduction

In the past decade, genetic manipulation in mammalian cells has become a routine practice for therapeutic ventures, given the promising advances in the safety and efficacy of gene-editing through clustered regularly interspaced short palindromic repeats (CRISPR) systems.¹ The CRISPR-associated (Cas)

enzymes, first discovered in *Streptococcus thermophilus* as a defensive shield against bacteriophages,² have expanded into a large family regarding the functional capability for DNA editing through the CRISPR/Cas 9 system and RNA manipulation through the CRISPR/Cas 12 & 13 system. In brief, the CRISPR regions contain short repeats (called spacers) that come from the nucleic acid fragments of invading viruses. The spacers provide a sequence-specific memory and targeted defence against the invasion of exogenous infection. During the immune response, CRISPR will transcribe into precursor transcripts that subsequently produce CRISPR RNAs (called crRNAs) which can bind with Cas nucleases, thus directing the precise identification and cleavage of the invader's nucleic acids.¹ Owing to its tremendous performance and fast iteration rate, the CRISPR/Cas system has recently been widely adopted in a variety of biomedical applications such as cancer therapy,

AIDS, liver diseases, cardiovascular diseases, and eye-related congenital defects.^{3–11} In addition, the biomedical bids of the CRISPR/Cas system as biosensors have been adapted recently, given the specific high-sensitivity enzymatic reporter unlocking (SHERLOCK) mechanism. The RNA-guided RNA endonuclease Cas13a could act as a nanosensor for the sensitive detection of

canine parvovirus-2 DNA.¹² Another example is the quick detection based on the CRISPR/Cas13a nanomachine to accurately detect the influenza virus through H7N9.¹³

Given their incredible capacity and accuracy for genome manipulation, CRISPR/Cas systems hold great potential for therapeutic applications. As genetic manipulation should occur in living cells, the delivery of a fully functional CRISPR/Cas system into live cells and specified target regions of the animals has become a deterministic step. To serve this purpose, many viral and nonviral cargo delivery systems have been employed for delivering CRISPR tools such as plasmid DNA, mRNA, or protein along with guide RNA into the cell and animal models.¹⁴ The traditionally used viral delivery systems give promising results at the expense of toxicity issues, let alone their immunogenic and tumorigenic properties prompting the demand for the discovery of safe and less toxic nonviral delivery systems.^{15,16} Different nonviral delivery approaches, including microinjection,¹⁷ electroporation,¹⁸ sonoporation,¹⁹ liposomes,²⁰ and CRISPR-delivering nanocomposites,²¹ have also been employed to overcome the issues related to viral delivery of CRISPR and to improve the efficiency and the targeted gene editing. Owing to the rapid development of nanotechnology and biomedical engineering techniques, nanocomposite-based

Muhammad Waseem Ghani

Muhammad Waseem Ghani received his master's degree from Guangdong Ocean University in 2021. He is currently pursuing his PhD in Cell Biology at the School of Nano-Tech and Nano-Bionics of the University of Science and Technology of China. His research mainly focuses on CRISPR/Cas9 delivery and genetic engineering of stem cells for modelling liver cancer in liver organoids.

Ambreen Iqbal

Ambreen Iqbal is currently studying for her PhD in Cell Biology at the School of Nano-Tech and Nano-Bionics, University of Science and Technology of China. Previously, she received her master's degree in 2022 from Guangdong Ocean University. Her research interests include the exploration of microRNAs related to the development and treatment of myocardial infarction.

Hammad Ghani

Hammad Ghani received his bachelor of medicine and bachelor of surgery (MBBS) degree from Nawaz Sharif Medical College Gujrat in 2020. Currently, he is working as a medical officer in the Basic Health Unit, Laleka, Primary and Secondary Healthcare Department, Punjab, Pakistan. His duties include clinical practice in the outdoor patient department.

Zixun Wang

Zixun Wang received his PhD degree from the City University of Hong Kong, Hong Kong, China, in 2019 and worked as a postdoctoral fellow at the City University of Hong Kong from 2019 to 2021. He has been an associate professor at Suzhou Institute of Nano-Tech and Nano-Bionics (SINANO), Chinese Academy of Science, since 2021. His current research mainly focuses on functional nanomaterials, biosensor development and spatial multi-omics.

Renjun Pei

Prof. Renjun Pei received his bachelor's and PhD degrees from Wuhan University and is currently working as a professor at the Suzhou Institute of Nano-Tech and Nano-Bionics, Chinese Academy of Sciences. His current research interest includes (1) biomaterials, organoids and 3D bioprinting with stem cells for tissue regeneration and (2) aptamer SELEX and applications, including in vivo imaging probes, isolation and analysis of circulating tumor cells and EVs, and targeted delivery.

nanocarriers have become one of the most promising strategies for CRISPR/Cas delivery due to their excellent biocompatibility, less toxicity, and enhanced delivery efficacy. Here, for the first time, we summarize the recent advances in the nanocomposite (including nanoparticle and nanostructure)-based delivery of CRISPR/Cas tools for targeted delivery and their respective therapeutic applications.

2 CRISPR/Cas systems and their therapeutic applications

The discovery of CRISPR systems and their application for genetic manipulation in eukaryotic cells rendered the exploration of this system in other species of bacteria for broadening the repertoire of CRISPR systems based on the Cas enzymes. The current classification of CRISPR/Cas systems includes two classes, 1 and 2, and their six subtypes, I–VI, based on the conformation and functionality of the Cas protein.^{22,23} CRISPR/Cas9, a type II system from *Streptococcus pyogenes* (SpCas9), consists of Cas9 nuclease, crRNA, and transactivating crRNA (tracrRNA), mainly used for programmed genetic engineering in mammals.^{24,25} The ortholog of Cas9 found in *Staphylococcus aureus* Cas9 (SaCas9)²⁶ and the recent discovery of other Cas enzymes (Cas12, Cas13, and Cas14) have added to the diversity of CRISPR/Cas systems.^{27,28} Further, the size of the Cas9 enzyme varies depending on the species of origin, as SaCas9, *Campylobacter jejuni* Cas9 (CjCas9),²⁹ and *Neisseria meningitidis* Cas9 (NmeCas9)³⁰ are more diminutive than SpCas9 easing the cargo loading and delivery.²⁶ In addition, a recently reported subtype of Cas12, CasΦ enzyme, applicable for genome editing and DNA detection with a molecular weight half that of Cas9 and Cas12a, offers easy packaging and delivery.^{31,32} Xu *et al.* created a small Cas12f mutant CRISPR system called CasMINI, which is equally efficient as Cas12a in gene activation and gene editing.³³ Similarly, the Cas14 enzyme, found in the archaea, capable of single-stranded DNA (ssDNA) cleavage in the target region, adds to easily deliverable CRISPR tools due to its compact size.³⁴

2.1 The principles of operation of CRISPR/Cas systems

Mechanistically, CRISPR/Cas9 induces double-strand breaks (DSBs) at the genomic loci following the direction of designed guide RNA (gRNA) that is complementary to the target sequence. The presence of the protospacer adjacent motif (PAM) sequence 'NGG' at the end of the gRNA target region enhances the DNA binding efficiency and cleavability of SpCas9. The induction of DSBs activates the DNA repair system to mend the DNA damage either precisely by homology-directed repair (HDR) or by error-prone non-homologous end joining (NHEJ) or microhomologymediated end joining (MMEJ).³⁵ The HDR mechanism permits only specific modifications, thus making it suitable for tailored genetic manipulation, while the NHEJ repair system works through insertions and deletions (indels), disrupting coding and noncoding sequences.³⁵ The recently discovered Cas system, Cas13, allows editing at

the RNA level providing a comprehensive application platform for research and medical drive.^{36–38} Hitherto, CRISPR/Cas systems have expanded into a large family with DNA and RNA editing capacity through CRISPR/Cas9 and CRISPR/Cas13, respectively.^{36,39–42}

The advances in CRISPR/Cas tools broadened the CRISPR-based repertoire of genome editing with different working modes. The variability in sequence recognition and respective functionality of different Cas enzymes increased the application range of CRISPR systems for biomedical applications and therapeutic purposes. The nucleotide base editing (BE) in DNA allows the conversion of C G to T A and A T to G C through changeover switches without generating DSBs.^{43,44} The function of prime editing (PE) could be achieved after linking Cas9H840A to an engineered reverse transcriptase enzyme, in combination with a PE gRNA (pegRNA) guiding the system to the required editing site.⁴⁵ A modified form of dead Cas13 (dCas13b) upon tethering to human RNA adenosine deaminase can induce specific adenosine deamination in RNA.⁴⁶ Other than the gene editing perks, CRISPR tools are also employed to repress gene transcription using an engineered form of Cas9, dead Cas9D10A/H840A (dCas9), which is unable to cleave DNA but can be used in CRISPR interference (CRISPRi) for gene knockdown through the fusion of dCas9 to the KRAB repressor.^{47,48} The gene activation role of CRISPR, termed CRISPR activation (CRISPRa), also involves dCas9 but in combination with the activator proteins such as VP64.^{39,49–51} The nucleic acid detection capacity of CRISPR/Cas12 and Cas13 systems based on SHERLOCK is being weighed for diagnostic and biosensor applications.^{52–54} With the evident advances in the CRISPR/Cas systems, the tailored genetic manipulation of most mammalian cell types is possible, and the efficacy of these systems is also being improved. Further, the presence of CRISPR systems in different species of bacteria provided the extensive functional diversity of genome editing.^{27,28,48} Despite the promising advances and improved functions of CRISPR/Cas systems, more research is essential for appropriately applying these systems to execute the required outcomes without harmful perturbations to the human body. Fig. 1 shows the schematic of the working principles of CRISPR/Cas tools for genetic manipulation.

2.2 Deliverable forms of CRISPR/Cas systems

CRISPR/Cas systems are delivered in multiple forms into the cells for genetic manipulation.^{55,56} Commonly, three delivery methods for the CRISPR/Cas system are implemented: plasmid DNA (pDNA) encoding the Cas enzyme and sgRNA, the RNA system with Cas mRNA and sgRNA, and the ribonucleoprotein (RNP) system with Cas protein and sgRNA.^{14,57,58} The Cas9 enzyme has a molecular weight of 160 kDa with a 7.5 nm diameter and a positive surface charge, making it difficult to deliver into the living systems.^{59,60} CRISPR pDNA transfection stands out for its superior stability and cost-effectiveness compared to the mRNA and RNP systems.⁶¹ However, practical pDNA-mediated genome editing faces unresolved delivery issues of compression, nuclear placement, and off-target risks.²⁶ In the delivery of CRISPR/Cas tools based on the RNA system, CRISPR/Cas delivery vehicles

Fig. 1 Working principles of CRISPR/Cas9/12/13 systems for DNA and RNA editing.

should be equipped to transport and protect the highly unstable RNAs of the Cas enzyme and its guide simultaneously, as well as control their release in the cytoplasm. Thus, the selection of the CRISPR delivery strategy and the optimization of its use have a significant impact on the efficiency of therapeutic gene editing. To satisfy the requirements of clinical gene therapy, the delivery vehicle should be able to stay in circulation for prolonged periods, increasing the chances of reaching the targeted site and improving delivery efficiency.⁶²

2.3 Therapeutic applications of CRISPR/Cas systems

The broadly spanning toolbox of CRISPR/Cas systems has been tested for therapeutic gene editing in different genetic diseases with promising results. The significant examples of therapeutic genetic manipulation in various genetic disorders include sickle cell anemia,^{4,5} thalassemia,⁶ cystic fibrosis disease,⁷ cancer,³ hereditary tyrosinemia type I⁸ alpha-1 antitrypsin deficiency,⁹ blindness,¹¹ Huntington's disease,^{41,63} Duchenne muscular dystrophy,⁶⁴ AIDS,¹⁰ and hepatitis B.⁶⁵ The therapeutic functioning of CRISPR/Cas systems in the aforementioned genetic diseases has been investigated in cell models or animal models. Further, the human organoid models are currently being assessed as preclinical tools in gauging the safety, efficacy, and accuracy of CRISPR-based therapeutic applications such as for cystic fibrosis disease in intestinal organoids.⁶⁶ In 2016, the first clinical trial of CRISPR/Cas9 mediated PD1 knockout (KO) T cells for treating lung cancer was carried out in China to evaluate the safety and efficacy.⁶⁷ The results reported CRISPR/Cas9-mediated gene-edited T cells as a safe and feasible clinical option for lung cancer patients.⁶⁸ Currently, ClinicalTrials.gov has listed more than 74 trials (<https://clinicaltrials.gov/>; accessed on 08/01/2023), including CRISPR/Cas9 and Ca12a, for treating genetic diseases, mainly cancer, hematological issues, and other genetic disorders. Recently, two trials for investigating the clinical diagnostic potential of CRISPR/Cas12a for pneumonia have also been listed.

3 Nanoparticle (NP)-based nanocomposites for CRISPR/Cas delivery

Different delivery approaches have been developed for therapeutic genetic modification based on the prodigious

therapeutic prospects of CRISPR/Cas systems.^{69–72} The safe and targeted delivery with sustained release (in some cases) of the CRISPR/Cas tools to the site of interest requires the carrying vehicle to deliver the cargo and protect it against enzymatic degradation and metabolic clearance. Therefore, the ideal advanced delivery systems should be equipped with efficient delivery in addition to their biocompatibility and biodegradation properties. With the convergence of biomaterials and nanotechnology, many attempts have been made to develop multifunctional nanoparticle-based nanocomposites for safe and feasible CRISPR/Cas delivery. This section will highlight the recent nanoparticle-based delivery systems, including lipid nanoparticles (LNPs), polymer-based nanoparticles, and hybrid nanoparticles, for targeted delivery of CRISPR/Cas tools and their therapeutic applications.

3.1 Lipid nanoparticles for CRISPR/Cas delivery

Lipid-based nanoparticles for delivering the genetic scissors are made up of physiological lipids. Despite their biocompatibility and biodegradability, the traditionally used liposomes are not widely applicable for CRISPR/Cas systems due to their poor stability, low encapsulation efficiency, and short shelf life.⁷³ The enormous success of mRNA vaccine technology in the fight against the COVID-19 pandemic has recently brought more attention to LNPs.^{74,75} LNPs are being widely developed and tested for delivering genetic materials to delineate their safety and efficacy to be considered as clinical delivery vehicles. To this end, the cationic carriers, DOTAP, DOPE, and cholesterol, are commonly used for shipping the negatively charged genetic material cargo after electrostatic interaction with the vehicle. Ionizable lipids are also used to carry negatively charged nucleic acids. LNPs containing ionizable lipids are typically used with conventional gears, such as cholesterol, phospholipid, and PEG derivatives, for particle, structural, and physiological stability, respectively.^{76,77}

3.1.1 LNPs for targeted CRISPR/Cas delivery. The nanoparticle-assisted delivery of CRISPR/Cas systems for *in vivo* genome editing has been pivoted for the liver owing to the accumulation of NPs in the liver after systemic administration. The commonly used NPs for hepatocyte-specific delivery of CRISPR/Cas systems are LNPs with high success rates and fewer toxicity issues.^{78,79}

Recently, Qiu *et al.* created an LNP-based method for delivering CRISPR/Cas9 and gRNA for *Angptl3* in mouse hepatocytes.⁸⁰

A single injection of LNPs containing Cas9 mRNA and *Angptl3* gRNA effectively edited the *Angptl3* gene in mice, lowering low-density lipoprotein (LDL) cholesterol by 57% and triglycerides by 29% for more than 100 days.⁸⁰ Mutations in the *Tymp* gene encoding thymidine phosphorylase lead to mitochondrial neurogastrointestinal encephalomyopathy (MNGIE). The LNPs delivered CRISPR/Cas9 and a *Tymp* cDNA to transport and activate a *Tymp* transgene into hepatocyte introns in a mouse model of MNGIE. The treated mice demonstrated a long-term (1-year) drop in plasma nucleoside levels associated with *Tymp* mRNA and effective enzymes in liver cells.⁸¹ Another recent study reported LNP-assisted delivery of the CRISPR base editor, ABE8.8, in cynomolgus monkeys as a preclinical demonstration. A single infusion of LNPs encapsulating ABE8.8 mRNA and *sgPcsk9* achieved almost absolute knockdown (KD) of *Pcsk9* in the liver with consequent reductions in PCSK9 and LDL cholesterol by about 90% and 60%, respectively. The persistence of the results for eight months after a single-dose treatment indicates the advancement of this approach towards clinical application.⁸² A biodegradable LNP (LNP INT01) delivered Cas9 mRNA along with end-modified sgRNA and entirely modified sgRNA targeting transthyretin (*Ttr*) to improve gene editing *in vivo* in mice. For 12 months after a single IV injection of LNP INT01, >97% of *Ttr* gene editing was achieved, decreasing the levels of the TTR serum protein by ~70%.⁷⁷ In 2020, the NTLA-2001 carrier system based on LNP, Cas9 mRNA, and *sgTTR* was formulated in an aqueous buffer for IV administration to demonstrate the clinical application.⁸³ For assessing the targeting efficiency, NTLA-2001 underwent preclinical development that included simulation modeling and *in vitro* studies. NTLA-2001 was particularly potent and produced saturating levels of *TTR* editing (93.7%) in primary human hepatocytes, resulting in 91% drop in *TTR* mRNA and 95% drop in TTR protein levels. Preclinical investigations in mice and monkeys revealed that a single dose of NTLA-2001 or its substitute Cyn-LNP resulted in long-lasting *TTR* editing and near-complete eradication of blood TTR protein expression with no side effects.⁸³ The LNP INT01 possessed the transient *Ttr* editing ability and was only tested in mouse and rat models. In contrast, the NTLA-2001 system for *TTR* gene editing was tested in human cell models, animal models, and Phase I clinical trials.

The advances in LNPs targeting liver cells for delivering CRISPR/Cas9 payloads have been effectively demonstrated in *in vitro* and *in vivo* preclinical models. To improve the delivery efficiency and gene therapy, the modification of LNPs and the delivery of different CRISPR systems have been tested. A significant advancement in this regard is the clinical trial of NTLA-2001 for *TTR* gene editing in liver cells. Systemic CRISPR/Cas delivery to non-liver organs remained a challenge until the recent discovery of LNPs with such delivery potential. Sago and colleagues developed a high throughput platform named FIND to discover LNPs. They found two LNPs, 7C2 and 7C3, for *in vivo* mRNA delivery to endothelial cell types in different organs. 7C3 efficiently transported RNAs of Cas9 and its guide to splenic endothelial cells, unlike LNPs, which target hepatocytes.⁸⁴ In another recent study, Wei *et al.* created

a modified LNP with a cationic lipid.⁸⁵ The modified LNP delivered the CRISPR RNP complexes to specified organs like the lungs and liver of mice following IV injection (Fig. 5B). Furthermore, the tailored LNP transported Cas9 RNPs into the skeletal muscle of the MDX mouse model, restoring dystrophin expression.⁸⁵ Mohanna *et al.* recently reported the delivery of LNP-RNPs for genetic correction in the small eye variant of the *Pax6* gene in an aniridia mouse model. The *ex vivo* results demonstrated the successful modification of mutation in 17% of mouse cortical neurons; however, the mutation correction was not detected in corneal cells when LNP-RNPs were injected in the mouse model's cornea. However the LNPs delivered the RNPs to the target site highlighting the potential of this delivery approach for therapeutic gene editing related to genetic disorders of the eye.⁸⁶

Despite the progress in delivering the genetic scissors to non-liver organs through LNPs, their targeted delivery to the specific site of genetic engineering is a big challenge following the systemic administration of LNPs. Recent research on LNP-CRISPR systems has mainly shifted towards selective organ targeting for target-specific genome editing to meet this challenge. Cheng *et al.*⁸⁷ developed a selective organ targeting (SORT) technique in which an additional lipid, a SORT molecule, was placed on the surface of conventional LNPs to increase tissue targetability. The SORT-LNPs selectively target several organs, including epithelial cells, endothelial cells, immune cells, B cells, and T cells, in the liver, lungs, and spleen (Fig. 2A). As an example of gene editing, SORT-LNPs delivered Cas9 mRNA and *sgPten* or Cas9 protein/*sgPten* in mice upon injection leading to the successful *Pten* gene editing in liver and lung cells.⁸⁷ Liu and colleagues synthesized multi-tailed ionizable phospholipids (iPhos) for *in vivo* gene editing in selective organs. iPhos synergized with helper lipids to form iPhos LNPs (iPLNPs) for specific organ targeting enabling tissue-selective gene editing through CRISPR/Cas delivery.⁸⁸ Dual delivery of Cas9 mRNA and *Tom1* sgRNA loaded in 9A1P9-5A2-SC8 iPLNPs specifically targeted the liver cells in mice upon IV injection. On the other hand, co-delivery of the same mRNA CRISPR system loaded in 9A1P9-DDAB iPLNPs targeted lung cells for gene editing. Similarly, Cas9 mRNA/*sgPten* co-delivery in mice by 9A1P9-5A2-SC8 and 9A1P9-DDAB iPLNPs presented efficient and targeted genetic manipulation in the liver and lungs, respectively.⁸⁸

A recent study reported that the systemic administration of oligonucleotide blocking *ICAM-2* sgRNA in SpCas9 mice bearing acute inflammation in the lungs reduced *ICAM-2* indels in hepatocytes and enhanced them in lung endothelial cells. In wild-type animals, LNP-mediated transfer of a repressing oligonucleotide, trailed by Cas9-disrupting siRNA, reduced *ICAM-2* genetic mutations in hepatocytes excluding splenic endothelial cells (Fig. 2C and D). This study demonstrated the tissue specific gene editing method following the delivery of CRISPR.⁸⁹ Compared to the LNPs developed by Cheng *et al.* and Liu *et al.* for selective organ targeting, this study reported using siRNAs for selective gene editing in different organs instead of modifying the LNP composition as mentioned in

Fig. 2 Targeted organ-specific CRISPR delivery through LNPs. (A) The schematic representation of the composition of SORT LNPs and their *in vivo* biodistribution. Reproduced with permission from (Cheng *et al.* 2020).⁸⁷ (B) Graphical representation of particular site cargo delivery of CRISPR/Cas RNPs by chemically tailored LNPs for tissue-specific gene editing. Reproduced with permission from (Sago *et al.* 2022).⁸⁹

the above two studies. This approach provides an additional way of targeting selective organs for genetic manipulation.

Overall, the selective organ delivery of CRISPR systems has been explored for assessing the effectiveness and safety of therapeutic gene editing in particular organs for targeted gene therapy. The selective delivery of CRISPR payloads in the liver, spleen, lungs, and tumor tissues has been accomplished hitherto.

3.1.2 Therapeutic applications of LNP-CRISPR/Cas systems.

The advances in assessing the competence and safety of LNPs for *in vivo* CRISPR cargo delivery have led to the assessment of preclinical gene editing for developing a therapy to cure various genetic diseases and cancer. This section will highlight the examples of therapeutic applications of LNP-CRISPR systems.

The therapeutic potential of 5A2-DOT-X for *in vivo* gene editing through CRISPR/Cas was tested in two therapeutic animal models by Wei *et al.* Three times per week injections of 5A2-DOT-10 LNPs carrying Cas9/*sgDmd* RNPs into the anterior tibialis muscles of the Ex44 DMD mouse model led to the refurbishment of dystrophin expression. Similarly, the tail vein injection of 5A2-DOT-5 LNPs containing Cas9/*sgPcsk9* RNPs in mice lowered the PCSK9 protein levels leading to the reduced level of harmful lipids associated with cardiovascular disorders. These two applications of 5A2-DOT-X LNPs have established the therapeutic efficacy of the LNP-CRISPR system for treating genetic illnesses.⁸⁵ Another recent study tested the therapeutic application of SORT LNPs, resulting in 100% decline in PCSK9 protein expression in the liver and serum samples of treated mice delineating the strong clinical application potential of this system.⁸⁷ Loss-of-function mutations in *Angptl3* reduced lipid levels in the blood, highlighting it as a promising therapeutic target for lipoprotein metabolism disorders. The LNP delivery platform developed by Qiu *et al.* for CRISPR/Cas9-based KO of *Angptl3* in the hepatic tissue of wild-type C57BL/6 mice reduced

the levels of serum ANGPTL3, LDL cholesterol, and triglycerides (Fig. 3A and B). These therapeutic events lasted for 100 days following the single-dose treatment, and the efficiency of this LNP platform was higher in comparison to the FDA-approved MC-3 LNP. This research provides proof of concept for the therapeutic application of this platform in patients with lipoprotein disorders and atherosclerotic cardiovascular disease.⁸⁰ In the clinical trial of LNP-CRISPR, a phase 1 clinical trial (ClinicalTrials.gov Identifier: NCT04601051) conducted by Intellia Therapeutics, NTLA-2001 led to a considerable decrease, 87%, of serum *TTR* protein content following the administration of a single dosage (0.30 mg kg⁻¹) in patients of transthyretin amyloidosis, with no significant hostile effects noted. In six individuals of hATTR amyloidosis with polyneuropathy, systemic treatment of NTLA-2001 was linked with a sustained decrease in serum TTR protein concentrations. After 24 months of NTLA-2001 infusion, safety and therapeutic activity outcomes will be assessed.⁸³ These results reveal the considerable potential of LNPs for conveying CRISPR/Cas9 to the human liver for therapeutic genetic manipulation. The targetable organs and genetic illnesses are anticipated to increase if LNP-CRISPR systems are improved further.

Mutations in the *kallikrein B1* (*KLKB1*) gene cause hereditary angioedema (HAE), characterized by swelling of the face, hands, and airways, which can be fatal in some cases. Intellia Therapeutics has started the phase 2 clinical trial of LNP-based NTLA-2002 (ClinicalTrials.gov Identifier: NCT05120830) for CRISPR/Cas9-based therapy of HAE by targeting *KLKB1*. The preclinical assessment of NTLA-2002 in cynomolgus monkeys and a humanized KLKB mouse model demonstrated that a single injection of NTLA-2002 resulted in 70% gene editing in *KLKB1* and >90% decrease in kallikrein protein levels.⁹⁰ Further, the single dose IV administration of NTLA-2002 at 0.3 mg kg⁻¹ in a partial hepatectomy (PHx) humanized

Fig. 3 Therapeutic gene editing through LNP-based targeted delivery of CRISPR tools. (A) Schematic representation of LNP-based delivery of CRISPR/Cas9 in mice to drive loss-of-function mutations in *Angptl3* to reduce lipid levels in the blood. (B) Serum ANGPTL3, LDL, and triglyceride levels in mice after 100 of LNP-CRISPR delivery. Adapted from (Qiu *et al.* 2021).⁸⁰ Copyright (2021) National Academy of Sciences. (C) Schematic of addressing tumor mechanics to unlock a double-checkpoint cancer blockage to promote cancer therapy. (D) The excised tumor volume shows modified LNP-CRISPR's *in vivo* therapeutic efficiency. Reproduced with permission from (Zhang *et al.* 2022).⁹³

KLKB1 mouse model resulted in 74% *KLKB1* gene editing and a 91% decrease in serum kallikrein before PHx and 71% gene editing and 94% decrease in serum kallikrein after 14 months of liver regeneration. These additional results delineate the permanence of NTLA-2002-based CRISPR/Cas9-induced genetic editing supporting the single-dose treatment for HAE patients.⁹¹

The LNP-CRISPR systems are on the verge of clinical application as cancer therapy based on the demonstrations in preclinical models thus far. In a mouse model of glioblastoma, a single intracerebral injection of *sgPLK1*-cLNPs killed tumor cells, slowed tumor development by 50%, and improved survival by 30%. Additionally, IP injections of *EGFR*-targeted *sgPLK1*-cLNPs permitted up to 80% editing of *PLK1* *in vivo*, reduced tumor formation, and increased survival by 80% in the mice, opening new avenues for cancer treatment, research, and genetic editing of non-malignant tissues.⁹² The combination of siFAK + CRISPR-PD-L1-LNP, created by Zhang *et al.*,⁹³ inhibited the spread of cancer and the formation of tumors in four mouse liver cancer models. In mice with MYC-driven hepatocellular carcinoma, treatment with siFAK plus CRISPR-PD-L1-LNPs reduced the expression of PD-L1 and increased the elasticity of the extracellular matrix (ECM), resulting in a significant extension of the animal's survival time (Fig. 3C and D). This recent example points out that using CRISPR gene editing in a multiplexed and generalizable strategy presents an innovative method for treating cancer.⁹³

Inclusively, the LNPs for CRISPR/Cas delivery have recently entered the clinical trials at Phase I and II levels for therapeutic genetic manipulation. NTLA-2001 and NTLA-2002 undergoing clinical trials are used for genetic illnesses, while the cancer

treatment options have also been studied with promising results through LNP-CRISPR/Cas delivery systems.

3.2 Polymer-based nanoparticles for CRISPR/Cas delivery

Polymers are widely employed in medication delivery into cells and animal models. The polymeric nanocarriers include dendrimers, micelles, nanoconjugates, nanocapsules, and polyplexes.⁹⁴ Akin to liposomes, the polymeric vectors are ideal for gene transfer since they have amino groups to form electrostatic complexes with negatively charged nucleotides without toxicity issues. This section will shed light on the recent advances of polymer-based NPs for CRISPR/Cas delivery.

3.2.1 Targeted CRISPR/Cas delivery mediated by polymer-based nanoparticles. The polymer-based nanoparticles, especially from natural sources, are biocompatible and could provide targeted delivery through specific receptors. The commonly used polymer, polyethyleneimine (PEI), causes toxicity, and to reduce the toxicity of PEI, Zhang *et al.* used cationic PEI-cyclodextrin (PC) as a cargo vehicle for a Cas9-sgRNA encoding plasmid.⁹⁵ PC was less cytotoxic than PEI, enabling high dosages or many transfections. The scientists discovered that PC packaging of the plasmid encoding Cas9 and sgRNA relied on the polymer to DNA ratio (N/P), with improved loading competencies obtained at larger N/P ratios and the maximum transfection (34%) attained at an ideal N/P ratio of 60.⁹⁵ Another group created a unique nanocarrier for combined cancer therapy made of chitosan (CS) laden with paclitaxel, an FDA-approved medication clinically tested against different cancers, and the *sgVEGFR2*/Cas9 plasmid. In addition to being biocompatible and biodegradable, this nanoparticle system was also pH-responsive for continued drug release patterns at

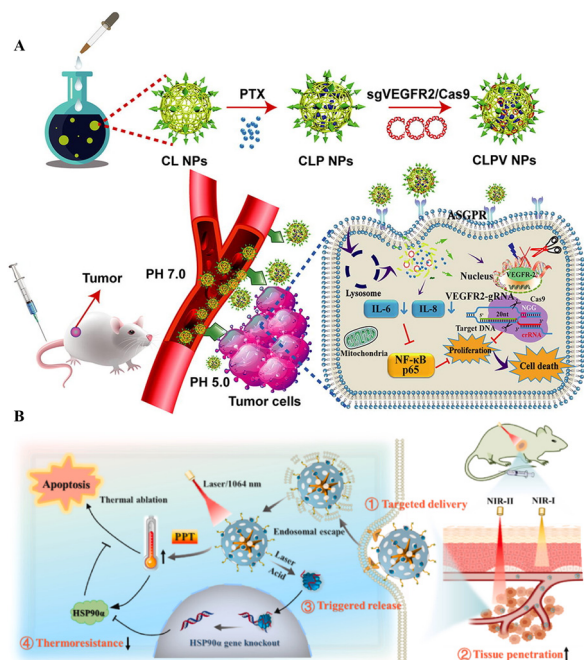

Fig. 4 Polymeric NPs for targeted delivery of CRISPR/Cas tools. (A) Tumor targeted delivery of VEGFR2-gRNA/Cas9 in a mouse model. the tumor site (Fig. 4A). Linking β -galactose-containing lactobionic acid to nanoparticles (NPs) that target carcinoembryonic antigen (CEA) results in increased drug absorption by liver cancer (HCC) cells that have ASGPR on their cell membrane surface, enhancing the targeting of the drug specifically to tumor cells. Upon *in vitro* and *in vivo* investigation in mice, the nanocomplex repressed >60% of VEGFR2 in HepG2 cells and decreased 70% of HCC tumor development, respectively.⁹⁶ In another study, Abbasi *et al.* demonstrated that in a PEG polyplex micelle, the simultaneous packaging of Cas9 mRNA and gRNA prevented sgRNA release after dilution, enhancing the sgRNA safety from enzymatic decay. The study team discovered that the polyplex micelle promotes genetic editing in the mouse brain.⁹⁷ A recent study reported a simple method for producing multi-branched gold nanostructures by caging them in mesoporous polydopamine loaded with the CRISPR RNP system targeting *HSP90 α* and coated by PEG-folic acid for targeted delivery. The complementarity between gene therapy and photothermal therapy (PTT) allowed increased penetration and decreased thermoresistance *in vitro* and *in vivo* (Fig. 4B).⁹⁸

The application of synthetic polymers like PEI and PC is less advisable due to their cytotoxic effects. Therefore, the application of natural polymers like chitosan, hyaluronic acid, and dextran with modifications is being investigated to safely deliver CRISPR/Cas systems. The polymer nanoparticle delivery systems allow the combined application of gene therapy and anticancer drugs or photothermal nano agents for PTT, increasing the targeted delivery chances and therapeutic potency of these systems.

3.2.2 Therapeutic potential of polymer nanoparticle-based CRISPR/Cas delivery systems. Polymeric NPs enable the efficient delivery of CRISPR/Cas tools *in vivo* because of their biocompatible and biodegradable properties along with cargo protection capacity. Recently, many studies reported using polymeric NPs for CRISPR/Cas delivery for therapeutic genetic manipulation. The preclinical results of paclitaxel and sgVEGFR2/Cas9 plasmid-loaded chitosan NPs targeting HCC in mice showed a 70% decrease in HCC development, advocating their potential for clinical consideration in the future.⁹⁶ A recent study reported the single base pair mutation correction in the *KCNJ13* gene associated with Leber Congenital Amaurosis (LCA16), a vision loss disorder. To this end, the adenine base editor (ABE8e) and sgRNA were used. The *in vitro* results demonstrated the correction of mutation and restoration of gene function. On the other hand, the injection of silica nanoparticles delivering ABE8e repaired 10% of retinal pigmented epithelium (RPE) cells in the LCA16 mouse model. This recent study provides a proof-of-concept for the bench-to-bedside transition for addressing pediatric blindness.⁹⁹

The polymer-based NPs are mainly employed for tumor therapy and the tumor-targeted delivery of CRISPR/Cas tools. The combinatorial polymer-based NPs have been proven target specific, efficient, and safe given the coating of polymers or linking with target-specific peptides or linkers.

3.3 Hybrid nanoparticles for CRISPR/Cas delivery

To make the NPs more durable and biocompatible, lipids, particularly phospholipids, are used for coating, as these materials are unstable in aqueous solutions and can have harmful effects.¹⁰⁰ Further, the formation of the hybrid nanocomposite with inorganic materials like calcium phosphate, carbon-based compounds, gold, silicon, and iron oxide has also been reported.¹⁰¹ The supramolecular formulations of these ions, in combination with CRISPR/Cas tools, are used as delivery vectors. For delivering the Cas9 and sgRNA plasmid into tumor cells, a functional lipid/gold nanocluster carrier was utilized to enhance the delivery efficiency. The surface modifications with DOPE, cholesterol and PEG are employed to improve cargo delivery efficacy.¹⁰² Coating NPs with cell membranes renders them biocompatible and increases the delivery efficiency of CRISPR/Cas tools.¹⁰³ Recently designed metal-organic frameworks (MOFs) and metal-organic cages (MOCs) have also been used to deliver gene editing scissors.¹⁰⁴ MOFs' high porosity and large capacity render them an auspicious tool for cellular CRISPR/Cas9 delivery.^{105,106}

3.3.1 Targeted delivery of CRISPR/Cas through hybrid nanoparticles. The combinatorial property of hybrid nanoparticles allows the conjugation of these nanoparticles with target-guiding agents for targeted cargo delivery. Poddar *et al.*¹⁰⁷ reported the ZIF-C mediated delivery of siRNA and CRISPR/Cas9 plasmid targeting *RPSA* at RNA and genomic levels, respectively, in prostate cancer (PC) cells.¹⁰⁷ Cell proliferation was prevented by shutting down the PC-specific *RPSA* gene by CRISPR/Cas9, suggesting promise as a PC treatment. They also revealed a technique for boosting ZIF-C intracellular

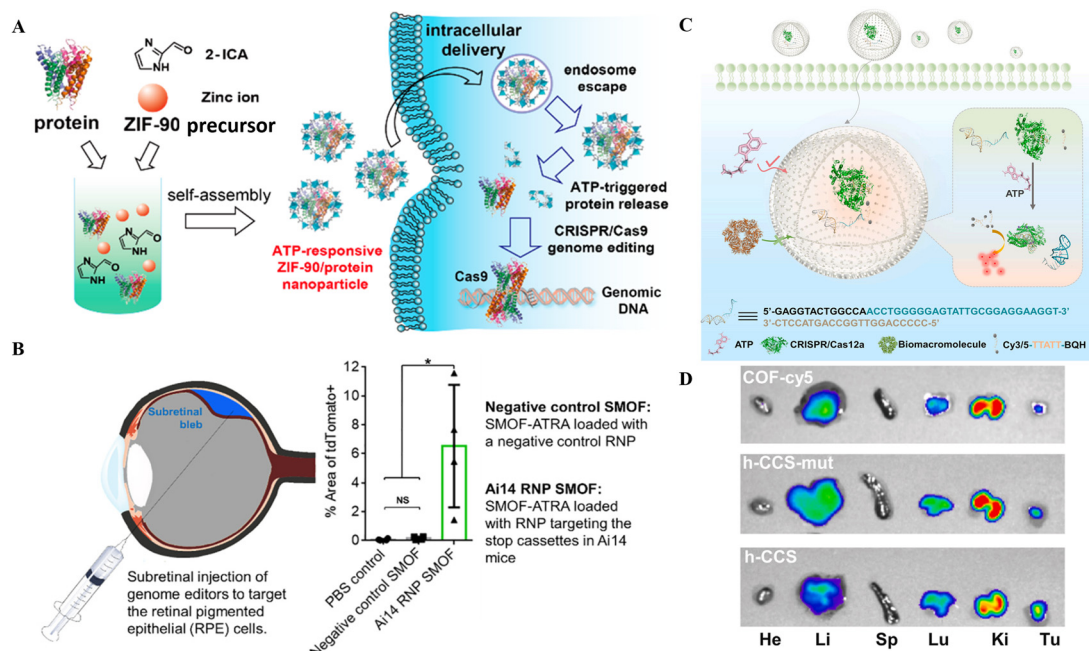

Fig. 5 CRISPR/Cas delivery through hybrid NPs for therapeutic applications. (A) An illustration showing how ZIF-90 can self-assemble for intracellular transport and produce genome editing thereafter. Reproduced from (Yang *et al.* 2019).¹⁰⁵ (B) Therapeutic application of the SMOF nanocomposite vehicle for CRISPR-based genome editing in retinal epithelial cells (Wang *et al.* 2020).¹⁰⁸ (C) Schematic of the ATP-triggered CRISPR/apptamer-based nanosensor for ATP imaging. (D) Nanoreactor-based *in vivo* ATP imaging of different organs of tumor-bearing mice. Adapted with permission from (Pan *et al.* 2022).⁷¹

transport and therapeutic efficiency by covering it with EGCG, which acts as a LAM67R-binding ligand. Coating ZIF-C with EGCG increased *RPSA* editing efficiency from 20% to 25%. Another study reported the pH-responsive silicon-MOF (SMOF) hybrid nanoparticles for encapsulating and delivering hydrophilic agents, including CRISPR/Cas9 RNPs, DNA, mRNA, and small molecule medicines.¹⁰⁸ Biocompatible SMOF NPs encapsulated Cas9 RNP efficiently (more than 97 percent). Silica offers additional conjugation sites for SMOF NP functionalization, for example, ligand modification. Using SMOF NPs, the authors edited the genome of the hereditary RPE.^{108,109} ATRA-conjugated CRISPR/Cas9@SMOF NPs injected subretinally in Ai14 mouse-directed effective genome editing in the RPE cells (Fig. 5B).¹⁰⁸ Additionally, cell membrane coating of NPs provides biomimetic functionality, *i.e.*, target specificity, to the delivery system, and helps improve the delivery of CRISPR/Cas tools.¹⁰³ Like cancer cell membranes, biomimetic membranes can increase NP uptake by homologous binding.¹¹⁰ A genome editing study showed that C3-ZIF-MCF suppressed EGFP expression 3-fold in MCF-7 cells. HeLa-coated C3-ZIF can only deliver Cas9 RNPs into MCF-7 cells, suggesting the cell specificity of membrane-coated ZIF-8 for genome editing. *In vivo* administration of C3-ZIF-MCF in mice bearing MCF-7 engrafted tumor confirmed target accumulation.

The ZIF-C approach by Poddar *et al.*¹⁰⁷ used the combinatorial approach of *RPSA* manipulation at the RNA and DNA level to effectively treat PC. Further, the EGCG coating of NPs improved the delivery efficiency and acted as an antioxidant and anticancer agent. In contrast, the combination of silica

with MOF allowed the addition of an ATRA targeting agent to the SMOF NPs, which helped in the RPE cell-targeted delivery of CRISPR/Cas9 RNPs. On the other hand, the coating of cell membranes onto NPs provides cell specificity and biomimetic properties. Overall, these studies provide the proof-of-concept for targeted delivery of CRISPR/Cas9 as well as other nucleotides and small molecule medicines through hybrid NPs.

3.3.2 Therapeutic potential of hybrid nanoparticle-based delivery of CRISPR/Cas systems. The combination of inorganic materials with polymeric compounds provides an efficient CRISPR/Cas delivery strategy. Gold NPs linked with an SH-spacer-crRNA in the core region act as the Cas9 binding element due to the affinity of Cas9 for crRNA.¹¹¹ The complex was covered with PEI, and donor ssDNA was electrostatically pierced on the surface, causing HDR to be downregulated in hematopoietic stem and progenitor cells.¹¹¹ Graphene oxide (GO) is also being exploited to deliver the Cas9 protein. The biocompatibility of GO was strengthened and functionalized through the PEG and PEI that formed the GO-PEG-PEI complex for the swift conveyance of RNP into human cells while sustaining Cas9 activity, with a gene-editing efficacy of about 39 percent.¹¹²

The ZIF-C vehicles developed by Poddar *et al.*¹⁰⁷ targeted PC resulting in retarded cell proliferation, hinting at the potential for PC treatment.¹⁰⁷ ZIF-90, another type of ZIF formed through the self-assembly of zinc ions and 2-ICA, has a comparable porosity to ZIF-8 with the ability to deliver CRISPR/Cas9 RNPs into cells.¹¹³ ZIF-90, after entry, destroys ATP within the cell liberating fluorophores for real-time ATP imaging.¹¹³ ZIF-90's

protein delivery and release efficacy are governed by ATP concentration in cells that is more in diseased cells (Fig. 5A). Thus, ATP-responsive ZIF-90 could be used for targeted gene therapy. More recently, Pan *et al.*⁷¹ reported a nanoreactor based on a covalent organic framework (COF) carrier packed with CRISPR/Cas12 and an aptamer-based nanosensor for ATP imaging. The hollow core of the COF encapsulated the nanoreactor based on CRISPR/Cas12, a fluorophore quencher and an ATP aptamer for *in vivo* imaging (Fig. 5C and D). The nanoreactor was suitable for ATP imaging in the cell and animal models.⁷¹

Zhang *et al.*¹¹⁴ developed a dual-locking nanoparticle (DLNP) capable of restricting the activation of CRISPR/Cas13a in tumor tissues. The polymer layer confers increased stability while circulating in the blood or when it is located in normal tissues. Additionally, it makes the endocytosis of the CRISPR/Cas13a system easier and activates gene editing when the DLNP is introduced into tumor tissue. In B16F10-bearing mice, DLNP demonstrates efficient activation of T cell-mediated antitumor immunity as well as immunosuppressive tumor microenvironment remodeling. This modification of the tumor microenvironment results in dramatically boosted and persistent antitumor effects.¹¹⁴

The hybrid combination of inorganic and polymeric nanomaterials improves the delivery of CRISPR/Cas tools. Additionally, the RNP-ZIF-90 NPs act as ATP-responsive agents for the intelligent delivery of CRISPR/Cas9 RNPs. More recently an ATP nanosensor based on a COF and an aptamer along with CRISPR/Cas12 was developed for ATP imaging. The RNP-ZIF-90 NPs used CRISPR/Cas9 for ATP-responsive genome editing in the target cells. In comparison, the ATP nanosensor based on the COF, aptamer, and CRISPR/Cas12 developed by Pan *et al.* can specifically be used for ATP imaging advocating the nanosensor potential of CRISPR/Cas tools for biomedical applications. The DLNP developed by Zhang *et al.*¹¹⁴ for delivering CRISPR/Cas13a for targeted tumor therapy also boosted the antitumor function of T-cells for effective cancer treatment. Altogether, the hybrid nanocomposites provide the additional capacity for linking, loading, and/or conjugating nucleotides, target specific molecules or small molecule medicines, and CRISPR/Cas tools for improved delivery and supporting genetic manipulation and treatment.

4 Nanostructure-based nanocomposites for delivery of CRISPR/Cas tools

The nanostructure-based nanocomposites are single or polycrystals with nanoscale grain size.¹¹⁵ The composition and size of nanostructures can vary depending on the type of nanostructure like extracellular vesicles, DNA nanostructures, and nanoneedles. Recently, the nanostructures have also been exploited to deliver CRISPR/Cas tools which will be discussed in this section.

4.1 Extracellular vesicle-based nanostructures for delivery of CRISPR/Cas tools

Extracellular vesicles, often known as EVs, are diverse populations of membrane vesicles that are discharged from cells of various types. There are three distinct categories of EVs, namely, exosomes, microvesicles, and apoptotic bodies, characterized by 40 to 150 nm, 100–1000 nm, and 50 to 5000 nm size, respectively.¹¹⁶ These lipid bilayer membrane vesicles are oriented in the same topological fashion as the plasma membrane, act as cell-to-cell communication carriers, and are immune-privileged; therefore, they are rarely removed by the immune system and escape hypersensitive reactions.^{2,117} EVs appear to be capable of transporting their contents from one cell to another over extended distances.² These properties make EVs suitable carrier vehicles for delivering CRISPR/Cas tools into the cell and animal models.

4.1.1 Targeted delivery of CRISPR/Cas systems through EV-based nanostructures. EVs are mainly used for encapsulating CRISPR RNPs for improving CRISPR/Cas9 genome editing. EVs encapsulating RNPs can be produced from different types of cells and embellished with cell surface receptor-specific agents for targeted CRISPR/Cas delivery. Regarding the target delivery, the binding of an aptamer (“com” as the RNA segment) and the aptamer-binding protein (ABP) increased RNP loading into EVs in addition to acting as ticket-targeted cargo delivery.¹¹⁸ ABP-“Com” fused to CD63 and com-modified sgRNA recruited RNPs to EVs. EVs containing ABP-Com coupled with CD63, VSV-G, and Cas9/gRNA were produced from HEK293T cells and were introduced to reporter cells. EVs delivered SaCas9 RNPs, which reinstated EGFP expression in the reporter cells by creating indels in the genome of cells. Multiple targets, including *DMD*, *GAPDH*, and *P53*, showed effective indel generation in cells. SaCas9 RNPs targeted introns 50 and 51 of *DMD* for multiplex gene editing, skipping a 2 kb sequence between introns. Injecting RNPs targeting *DMD* exon 53 into del52hDMD/mdx mice’s TA muscle caused indel development.¹¹⁸ Modifying the surface of EVs helps to improve CRISPR/Cas functioning. To this end, Zhuang *et al.*¹¹⁹ created a delivery mechanism using DNA aptamers on exosomes to transport gene-editing RNP complexes. Cas9 and sgRNA RNPs were sonicated or frozen and thawed into EVs. Then, DNA nanostructures were added to RNP-loaded EVs (TDNs). TDNs were employed to show that DNA aptamers coupled on the EV membrane enhanced the target cell uptake (Fig. 6B). *In vitro*, the TDN-EV cholesterol/apptamer induced indels in 43% of HepG2 cells. RNP complexes targeting *WNT10B*, HCC target, knocked it down in liver cancer organoids. TDN1-EV-RNPs suppressed the *ex vivo* formation of tumor organoids. *In vivo*, TDN1-EV-RNPs (1.0 mg kg^{−1}) stopped tumor growth in mice with HepG2 xenografted tumors.¹¹⁹

Burkitt’s lymphoma, diffused large cell lymphoma, multiple myeloma, and acute lymphocytic leukemia all have high levels of MYC overexpression.¹²⁰ As a result, employing the CRISPR/Cas9 technology to target *MYC* could produce a favorable therapeutic effect in cancer treatment. Chimeric-antigen receptors (CAR) are used for tumor targeting.¹²¹ In this context, anti-CD19-CAR-EVs and unmodified EVs were electroporated

Fig. 6 CRISPR/Cas RNPs' delivery through EVs. (A) Schematic representation of anti-CD19-CAR-EV mediated cancer therapy. Electroporation loads MYC-targeting CRISPR/Cas9 into EVs. Anti-CD19-CAR-EVs boost the cargo's efficiency in CD19-positive tumor cells. Adapted with permission from (Xu *et al.* 2020).¹²¹ (B) Tumor targeted delivery of genetic scissors through TDNs. Reproduced with permission from (Zhuang *et al.* 2020).¹¹⁹

with *MYC*-targeting sgRNA/Cas9 plasmids (Fig. 6A). Anti-CD19-CAR-EVs reduced CD19⁺ Raji and Nalm6 cell growth more than unmodified EVs. In mice with Raji xenografts, anti-CD19-CAR-EVs gathered in tumor areas, but unchanged EVs were identified in other tissues.¹²¹ Ye *et al.*¹²² created a modified exosome (M-CRISPR/Cas9 exosome) for improved encapsulation of CRISPR/Cas9 components. Researchers artificially generated exosomes by combining GFP and GFP nanobodies fused with CD63 and Cas9 proteins. Due to the selectivity of GFP-GFP nanobodies, Cas9 proteins can be precisely and effectively loaded into exosomes. Using A549^{stop-DsRed} reporter cells, they found that CRISPR/Cas9-functionalized exosomes successfully suppressed the target gene in recipient cells.¹²²

These studies highlight the targeted delivery of CRISPR/Cas9 tools after adding aptamers for target-specific binding. Moreover, the presence of CD proteins on the surface of EVs or exosomes stipulates the evasion of these delivery agents from the immune system and allows for long-term stay in circulation, increasing the chances for delivery to the target tissue. However, these studies only reported the encapsulation and delivery of CRISPR/Cas9 as RNPs rather than the mRNA form, given the unsuitability of SpCas9 mRNA encapsulation. All in all, the biomimetic, immune evasion, and target-specific delivery properties of EVs have added to the CRISPR/Cas9 delivery options for biomedical applications.

4.1.2 Therapeutic potential of EV-based delivery of CRISPR/Cas systems. The cellular origin of EVs makes them safe and biocompatible cargo delivery agents for therapeutic applications. To that end, Luo *et al.*¹²³ used CRISPR/Cas9-carrying exosomes to treat murine liver fibrosis. Plasmid DNA containing the genes for dCas9-VP64 and *HNF4a* was transfected into murine-producer cells. Producer cell exosomes were incubated with hepatic stellate cells (HSCs) from the fibrotic mouse. Inducing *HNF4a* expression caused fibrosis-associated

HSCs to become hepatocyte-like cells.¹²³ Recently developed GEDEX, "genome editing with designed extracellular vesicles," uses EVs to deliver CRISPR/Cas9.¹²⁴ Transfected HEK293 cells secreted EVs with Cas9/gRNA RNP complexes. *In vitro*, GFP-GEDEX reduced fluorescence in over 70% of HEK293-GFP cells. The IP injection of GFP-GEDEX into B6-EGFP mice decreased eGFP fluorescence by 50% after 5 days. For overexpression, dCas9 was attached to VP64-p65-Rta to create CRISPRa (VPR). GEDEX with dCas9-VPR and a sgRNA directed at the *Actc1* gene promoter were used to upregulate endogenous gene expression, resulting in seven-fold increased *Actc1* mRNA expression. Upregulating *HGF* gene expression may promote liver regeneration using the GEDEX system. Hydrodynamically delivered GEDEX targeting *HGF* increased HGF levels in harvested livers and improved hepatocyte functionality in the hepatotoxic mouse model. Upregulating genes associated with tissue regeneration is a promising therapeutic bid of EV-delivered CRISPR/Cas9.¹²⁴

Gee *et al.* employed gene editing by developing an all-EV delivery system termed NanoMEDIC.¹²⁵ HEK293T producer cells were lipofected with FKBP12 and FRB-Cas9 to produce EVs. After AP21967 treatment, EVs were introduced to HEK293T cells expressing a *DMD1*-targeting sgRNA. NanoMEDIC created *DMD1* indels in up to 40% of human iPSCs. NanoMEDIC could target the dystrophin gene yielding 90% exon skipping in DMD patients' skeletal muscle cells derived from the iPS cells (Fig. 7A and B). For *in vivo* testing on transgenic mice, the single IM injection of NanoMEDIC was associated with exon skipping in *Mdx* mice which lasted for 160 days.¹²⁵ The NanoMEDIC system's stability is superior to existing *in vivo* genome editing technologies; DMD sufferers now have hope, thanks to the researchers for this development. HEK293-Exo and SKOV3-Exo were isolated by Kim *et al.*¹²⁶ from HEK293 and SKOV3 cells, respectively. Electroporation was used for packaging exosomes with sgRNA/Cas9 targeting *PARP-1*. With cancer-derived

Fig. 7 *In vivo* gene editing through EV-based CRISPR/Cas delivery. (A) Dystrophin gene editing in mice after IM injection of NanoMEDIC. (B) The exon skipping in mice treated with NanoMEDIC injection. Reproduced from (Gee *et al.* 2020).¹²⁵ (C) Biodistribution of the exosome-mediated CRISPR nanocarrier targeting tumor cells in mice. (D) Effect of SKOV3-Exo-based delivery of CRISPR/Cas9 for gene editing a xenografted tumor in mice. Reproduced with permission from (Kim *et al.* 2017).¹²⁶

exosomes, CRISPR/Cas9 inhibited *PARP-1* in SKOV3 cells, and SKOV3-Exo induced indels with 27% efficacy in the *PARP-1* gene. In mice, SKOV3-Exo injections (intravenous or intratumoral) reduced tumor weight and volume. The combined loading of cisplatin and CRISPR/Cas9 in SKOV3-Exo inhibited SKOV3 cell proliferation by 57% *in vitro*. The inhibition of *PARP-1* sensitized the cancer cells to cisplatin, promoting its anticancer activity. *In vivo*, tagged exosomes were injected into the tail veins of SKOV3 xenograft mice, resulting in SKOV3-Exo accumulation at the tumor sites working as an anticancer agent (Fig. 7C and D).¹²⁶

The use of epithelial cells and cancer cells for the production of EVs encapsulating CRISPR/Cas tools diversifies the delivery function of EVs. In the case of GEDEX and NanoMEDIC, the EVs were produced from the epithelial cells with different applications depending upon the encapsulated CRISPR/Cas components. The GEDEX system contained dCas9, which was involved in *HGF* overexpression, while the NanoMEDIC system worked through indel generation for exon skipping in the target gene. In contrast, the SKOV3-Exo system developed by Kim *et al.* can be used explicitly for cancer treatment, given the dual function of genetic manipulation and chemotherapy. The encapsulation of CRISPR/Cas tools in EVs and exosomes added to the delivery options for therapeutic genetic manipulation with promising results.

4.2 DNA nanostructure-based delivery of CRISPR/Cas tools

DNA macromolecules are biocompatible and traceable; therefore, their use in nanomedicine is growing.¹²⁷ DNA nanostructures serve as customizable CRISPR delivery systems protecting, targeting, and releasing the cargo.¹²⁸ Recently, the use of DNA nanotechnology to deliver gene-editing tools has gained attention and is being widely researched for establishing an efficient and safe CRISPR/Cas delivery system. The recent developments

in targeted delivery and therapeutic potential of DNA nanostructures as CRISPR/Cas delivery systems will be discussed in this section.

4.2.1 Targeted CRISPR/Cas delivery through nanostructured DNA-based-nanocomposites. DNA nanostructures bind with the CRISPR/Cas tools through complementary binding and deliver the cargo to the targeted site through receptor binding. DNA nanostructures' complementarity and target recognition capacity make them unique CRISPR/Cas delivery options. Different methods for loading or binding the CRISPR/Cas tools to the DNA nanostructures are deployed for targeted delivery. One of the simplest methods is covalently attaching seven ssDNA arms to β -cyclodextrin cores treated with azide groups.¹²⁹ To create a sgRNA/Cas9/antisense-nanoparticle (RCA@NP), these DNA structures might be joined with a linker and sgRNA. For cancer cell targeting, aptamer linking improved the targeted transport of RCA@NP complexes, and cargo liberation was proven effective with glutathione and RNase breakdown. Through DNA self-assembly, branched DNA is linked with RCA@NP for targeting *PLK1*. The biocompatible DNA nanocarrier led to tumor growth inhibition in mice showing its therapeutic implication.¹²⁹

Another recent study reported the DNA nano clews as a CRISPR/Cas delivery system. The sgRNA/Cas9 complexes were loaded in the nano clews, and loaded clews were coated with PEI for endosomal carrier escape. Besides, with the advancement of DNA nanotechnology, DNA nano clews are reported coated with polymers that are attached to positively charged carriers, which are released when the pH changes from physiological to acidic.¹³⁰ *In vitro* delivery of a Cas12a/CRISPR RNP system linked with decreased cholesterol blood levels in mice was achieved. Reduced PCSK9 expression was connected to PCSK9 disruption (48%) and lower cholesterol levels (45%).¹³⁰ Ding *et al.*¹³¹ developed a similar delivery technique using a DNA-based nanogel. First, DNA-grafted polycaprolactone brushes

Fig. 8 DNA nanostructures for CRISPR/Cas delivery. (A) Design of the DNA nanogel-based CRISPR carrier. (B) Gene editing mechanism after cell internalization of the nanocarrier. (DNA-g-PCL) were loaded with sgRNA/Cas9 complexes and crosslinked using DNA linkers (Fig. 8A and B). The non-cationic nanogel protected sgRNA/Cas9 complexes from nuclease digestion and allowed for progressive release. The *in vitro* demonstration showed the knockdown of EGFP in HeLa cells after nanogel/Cas9/sgRNA delivery, demonstrating its targeted gene editing efficiency.¹³¹ Further research established that these nanogels could even be layered with PEI to enhance endosomal escape, similar to the nano clew coating with PEI. Poly-A mRNA tails hybridized with poly-T nanogel (poly-T20-grafted polycaprolactone) segments (T20-g-PCL). Packing and conveying Cas9-mRNA and EGFP-mRNA cargo confirmed their functionality in HeLa and HEK-293 cells.¹³² However, the efficacy of targeted gene editing after cargo delivery of CRISPR/Cas systems through nanogels in these two studies has only been demonstrated *in vitro*. Thus, the *in vivo* administration of these systems for clinical gene therapy is awaited. Wu *et al.*¹³³ reported a broad technique for constructing a dsDNA-RNP fused nanostructure by folding dsDNA with a CRISPR/dCas9/12a system. They fused dCas9 and dCas12a *via* a stimuli-responsive peptide linker. Covalently bivalent dCas9-12a RNPs (staples) activated by gRNAs may recognize target sequences in the dsDNA scaffold and bind them to generate DNA-RNP hybrid nanostructures (Fig. 8C and D). The biologically derived hybrid nanostructure may shield genetic information when folded as well as induce stimuli-responsive gene transcription. This DNA folding and unfolding method enhances DNA nanotechnology for delivering the CRISPR system.¹³³

The targeted CRISPR/Cas delivery through DNA nanostructures is still in the early stages; therefore, their limited *in vivo* usage has been reported. However, the results of studies thus far indicate their efficacy to be considered as the clinical delivery vehicle for CRISPR/Cas delivery. On the other hand, the co-delivery of dCas9 and dCas12a allowed for multiplexed genetic manipulation, which stands out among the other CRISPR delivery systems.

4.2.2 Therapeutic potential of DNA-nanostructure-CRISPR/Cas systems. Owing to their strong biocompatibility and traceability, the DNA nanostructures are promising candidates for

therapeutic genetic manipulation by delivering CRISPR tools. The RCA@NP complexes have been used for *PLK1* targeting through sgRNA/Cas9 delivery. Cancer cell targeting inhibited tumor development in mice, showing the system's therapeutic potential (Fig. 9C).¹²⁹ Another piece of evidence supported that the a Cas12a/CRISPR RNA-RNP system reduced PCSK9 expression due to *PCSK9* disruption (48%) and lowered cholesterol levels (45%). Further, this system lowered the serum cholesterol levels in mice advocating the therapeutic ability of this system (Fig. 9D).¹³⁰ These pieces of evidence support the therapeutic potential of CRISPR-based gene therapy by delivery through DNA nanostructures. Recent work demonstrated a co-delivery system built on ultralong ssDNA with attachment sites for sgRNA, DNAzyme sequences, and HhaI cleavage sites.¹³⁴ DNA strands were condensed into nanoparticles and joined with HhaI enzymes that degraded in acidic pH using the DNAzyme cofactor Mn^{2+} . The acidic environment inside the lysosome facilitated the degradation of the polymer, allowing it to bind to the HhaI enzyme and cut at specific cleavage sites. This released the sgRNA/Cas9 and DNAzymes, enabling gene editing related to breast cancer through Cas9 and mRNA editing through DNAzymes (Fig. 9A and B).¹³⁴

The therapeutic genetic manipulation through CRISPR delivery using DNA nanostructures has not been extensively studied. A few studies have reported the preclinical demonstration in animal models, with a particular example of DNCs for treating breast cancer.

4.3 Nanoneedle-assisted delivery of CRISPR/Cas systems

Nanoneedles are vertical nanostructures with a high aspect ratio that may accurately influence complex interactions at the cell interface, allowing for active intracellular administration. This nanotechnological innovation has already permitted the establishment of effectual intracellular channels for delivering cell-impermeant payloads. A variety of one-dimensional (vertically arranged) nanostructures can be used as nanoneedles within these categories: nanowires,^{135,136} nanopillars,^{137,138} nanocones,^{139,140} nanostraws,¹⁴¹ and nanotubes.¹⁴²

(D) Charge-reversible DNA nano clews carrying Cas12a/crRNA wrapped in the Gal-PEI-DM polymer for *in vivo* CRISPR delivery. Adapted with permission from (Sun *et al.* 2020).¹³⁰

Many ways of mechanically perforating cell membranes and delivering molecular payloads and Cas9 RNPs have been reported in nanoneedles and nanowires. Mechanistically, the nanoneedles are laid on the top of cells, and then the cells are centrifuged at a specified speed for a brief duration to poke the cells with nanoneedles, followed by removal of nanoneedles to allow the delivery of cargo into the cells. The centrifugation speed, time, acceleration and deceleration are critical for cell membrane penetration in these approaches. In a study by Kawamura *et al.*, it was discovered that inserting 200 nm nanoneedles at a rate of 10 mm s^{-1} significantly increased the detection efficiency of cellular proteins due to the insertion efficacy.¹⁴³ Because there is no substantial change beyond 10 mm s^{-1} , a needle with a diameter of 200 nm should have a velocity of 10 mm s^{-1} or greater. They used silicon micro-fabrication technology to create monolithic nanoneedle arrays with 200 nm diameter and 40 mm length and nanoneedles

spaced 10 mm from each other for molecular delivery and mechanically separating the cells targeting intracellular antigens. The introduction of Cas9 RNPs using this nanoneedle array resulted in a target gene KO efficacy of around 16 percent in mouse mammary cancer cells.¹⁴⁴

Cell membrane penetration is effectively decreased if the nanoneedle array is submerged in cell-seeded media and permitted to come into contact with the cells *via* sedimentation. Chen *et al.*¹⁴² employed arrays of silicon nanotubes (300 nm inner tube diameter, 2 μm height, and 0.16 NT m^{-2} density) to administer Cas9 RNPs to murine fibroblasts, with a 6 percent indel efficiency for *Hprt* gene disruption. This could be because the needle-like substance stimulates membrane invagination and endocytosis when it touches the cells.¹⁴⁵ Endocytosis is the mechanism behind the needles' sluggish approach to the cells. GFP-expressing B16F10 mouse melanoma cells were successfully wiped off by a gold nanowire driven by ultrasound to transduce

Fig. 10 Gene editing through the use of mechanically responsive mechanisms. The morphology of nanoneedle array and the schematic of RNP loading and releasing mechanism from the nanoneedles. Adapted from (Yamagishi *et al.* 2019).¹⁴⁴ © 2019 MDPI.

Cas9 RNPs.¹⁴⁶ According to this finding, the physical driving force imparted on nanoneedles appears critical for transmembrane transmission. In another study, silicon nanoblade chips (NB-chip) and the Cas9 RNP complex were integrated into a two-dimensional array of tens of thousands of nanoneedles to deliver Cas9-sgRNA into human cells (Fig. 10).¹⁴⁴ FP10SC2 mouse breast cancer cells were used to prove the approach of delivering Cas9-sgRNA *via* a nanoneedle array, which knocked out nestin in FP10SC2 mouse breast cancer cells. This method's gene disruption efficiency in HeLa and murine mammary cancer cells proves its *ex vivo* gene-editing efficacy. Neuronal cells in 1 mm-thick brain tissues are too deep for typical nanoneedles (10 nm) to reach. Therefore Nomano *et al.* used nanoscale-tipped wire arrays with diameters of 100 nm and wire lengths of 200 nm to deliver biomolecules in slices of brain tissue. The nanotip arrays interact with cells in deep brain tissue to deliver FP expression vectors to target cells for electrophysiological monitoring and neuronal transfection. Pressing a nanotube wire array distributes plasmid DNA in multiple-neuronal cells in a brain slice with minor cell damage. A CRISPR/Cas9 genome-editing vector targeting *Cetn1* can genetically modify the role of living neuronal cells in the brain and the pacemaker cells of mammalian circadian rhythms.¹⁴⁷

The application of nanoneedles for CRISPR delivery has mainly been studied *in vitro* in the cell models, given their unsuitability for *in vivo* delivery in circulation owing to their structural configuration and coated CRISPR/Cas tools delivery method in the target cells. However, the nanoneedles can potentially deliver the CRISPR/Cas systems on the surface cells, such as skin and brain cells, after surgery.

5 Conclusion and outlook

Since their discovery, the CRISPR/Cas tools have been diversely weighed for therapeutic applications. CRISPR technology has already begun to answer many fundamental and complex concerns about gene therapy in numerous diseases. Albeit off-target activity and genome damage are potential challenges for CRISPR applications, the methods and technologies to assess and eliminate them are available and likely would not limit its clinical usage. An example of reduced off-target activity is the CRISPR/Cas12b system, which could be more effective for human genome editing than the CRISPR/Cas9 systems. The other likelihood to reduce off-target activity is the RNP system, which reduces the time limit for Cas enzyme activity and the chances of genome insertion. The application of CRISPR/Cas systems relies on safe, targeted, and efficient delivery. Despite being highly effective for transfection, the viral delivery vector is labor-intensive and expensive, and has repercussions to be used as the clinical CRISPR delivery system. Therefore, developing secure and reliable delivery systems presents a possible solution. In this regard, the recent advances in nanocomposite delivery systems, including nanoparticles and nanostructures, have proven effective for the targeted delivery of CRISPR/Cas systems and their respective therapeutic applications. However, further modification of these delivery systems is a requisite for

enhanced cellular uptake, target site-specific delivery through blood vessel permeability, and addressing the major limitation of tissue penetration into deeper regions of different organs. The nanoneedle arrays with long-wired shapes could be the candidates for delivery into the deeper tissues of the body.¹⁴⁷

Comparatively, the wide variety of NPs and the extensive background research related to NPs and their drug or nucleotide delivery bids have made them more suitable candidates for CRISPR/Cas delivery. Further, the flexibility for chemical modification, composite formation capacity, and conjugation of target-specific linkers allow the effective loading and target-specific delivery of CRISPR/Cas. To this end, the chemical modification of LNPs rendered the delivery system more efficient and organ selective.⁸⁷ The selective organ targeting for CRISPR/Cas delivery is mainly limited to organs like the liver, spleen, kidney, and lungs. The development of nanocomposite delivery systems to deliver CRISPR/Cas systems to other organs would increase the repertoire of therapeutic applications of CRISPR/Cas tools. In comparison, the delivery of CRISPR/Cas systems through nanostructures is still in its infancy, with some progress in recent years. The nanostructures have limitations, including maintaining conditions, physical/chemical parameter balancing, and diffusion issues, limiting the satisfactory CRISPR/Cas delivery through nanostructures. The delivery of CRISPR/Cas tools through nanostructures is mainly performed in the RNP form, while the NPs have been reported to deliver CRISPR/Cas tools through pDNA, mRNA, and RNP. Overall, the wide variety of nanocomposites, NPs, and nanostructures have been extrapolated recently for developing a safe and efficient CRISPR/Cas delivery system for clinical purposes.

The advanced CRISPR/Cas tools, such as the recently reported subtype of Cas12, Cas Φ enzyme, Cas12f, with a molecular weight half that of Cas9 and Cas12a, would be easy to package and deliver.^{33–35} Similarly, the Cas14 enzyme, found in the archaea, capable of ssDNA cleavage in the target region, adds to easily deliverable CRISPR tools due to its compact size.³⁴ Abbott *et al.* recently found CRISPR/Cas13-based therapy, PACMAN, against SARS-CoV-2 utilizing *Ruminococcus flavefaciens* Cas13d. PACMAN destroys SARS-CoV-2, disrupts IAV genomic sequences in human lung epithelial cells, and prevents viral replication. The authors claimed that PACMAN could be a pan-coronavirus inhibitory method to manage SARS-CoV-2 and its previous variants in animals and people.¹⁴⁸ The nanocomposite-based delivery of PACMAN to the lungs could be its therapeutic application after developing such a delivery system.

The use of 3D cell models, primarily human tissue-derived organoids, has not been tested much for the delivery of CRISPR/Cas tools through nanocomposites. However, the organoids provide better preclinical modeling for their capacity to mimic patients' genetic setup and experiment with mutation correction through nanocomposite-based delivery of CRISPR/Cas tools.^{66,119} Alternatively, the nanocomposite-based delivery of CRISPR/Cas tools into the organoids from iPS cells or normal donor tissues can be used for modeling cancer and other genetic diseases for unraveling the underlying molecular mechanisms of genetic diseases or drug development.

Overall, the convergence of nanotechnology and biomedicine for CRISPR/Cas delivery has gained popularity and is being assessed for developing clinical-grade delivery systems. The LNPs and polymeric NPs, in addition to the nanostructure nanocomposites, are promising candidates winning the race towards clinical application as CRISPR delivery systems. The recent developments in CRISPR/Cas systems and delivery systems indicate that CRISPR will enter clinical practice in the near future.

Abbreviations

ABE8.8	Adenine base editor 8.8-m	H7N9	Influenza A virus subtype H7N9
ABP	Aptamer binding protein	HAE	Hereditary angioedema
Actc1	Actin alpha cardiac muscle 1	hATTR	Hereditary transthyretin-mediated
AIDS	Acquired immunodeficiency syndrome	HCC	Hepatocellular carcinoma
Angptl3	Angiopoietin-like 3	HDR	Homology-directed repair
ASGPR	Asialoglycoprotein receptor	HEK293 cells	Human embryonic kidney 293 cells
ATP	Adenosine triphosphate	HGF	Hepatocyte growth factor
ATRA	All-retinoic acid	HNF4a	Hepatocyte nuclear factor 4 alpha
BE	Base editing	Hprt	Hypoxanthine guanine phosphoribosyl transferase
BP	Black phosphorus	HSCs	Hepatic stellate cells
CAR	Chimeric antigen receptor	HuR	Human antigen R
Cas	CRISPR-associated	iPhos	Ionizable phospholipids
CD19	CD19 molecule	iPLNPs	iPhos NLPs
CD63	CD63 molecule	iPSCs	Induced pluripotent stem cells
Cetn1	Centrin 1	ICAM-2	Intercellular adhesion molecule 2
COF	Covalent organic framework	Indels	Insertions and deletions
COVID-19	Coronavirus disease 2019	IP	Intraperitoneal
CRISPR	Clustered regularly interspaced short palindromic repeats	IV	Intravenous
CRISPRa	CRISPR activation	KCNJ13	Potassium inwardly rectifying channel subfamily J member 13
CRISPRi	CRISPR interference	KD	Knock down
CjCas9	<i>Campylobacter jejuni</i> Cas9	KLB1	kallikrein B1
crRNA	CRISPR RNA	KO	Knockout
CS	Chitosan	LCA16	Leber congenital amaurosis
dCas	Dead Cas	LDL	Low density lipoprotein
DLNP	Dual-locking nanoparticle	LNPs	Lipid nanoparticles
DMD	Dystrophin muscular dystrophy	MDX	Duchenne muscular dystrophy
DNA-g-PCL	DNA-grafted polycaprolactone brushes	MMEJ	Microhomologymediated
DOTAP	1,2-Dioleoyl-3-trimethylammoniumpropane	MNGIE	Mitochondrial neurogastrointestinal encephalomyopathy
DOPE	Dioleoylphosphatidylethanolamine	MOCs	Metal-organic cages
DSB	Double-strand break	MOFs	Metal-organic frameworks
ECM	Extracellular matrix	MYC	MYC proto-oncogene bHLH transcription factor
EGCG	Epigallocatechin gallate	NHEJ	Non-homologous end joining
EGFP	Enhanced green fluorescent protein	NmeCas9	<i>Neisseria meningitidis</i> Cas9
EGFR	Epidermal growth factor receptor	NP	Nanoparticle
EV	Extracellular vesicle	PAM	Protospacer adjacent motif
GAPDH	Glyceraldehyde 3-phosphate dehydrogenase	PARP-1	Poly(ADP-ribose) polymerase 1
FKBP12	FKBP prolyl isomerase 12	Pax6	Paired box protein
GEDEX	Genome editing with designed extracellular vesicles	PC	Prostate cancer
GFP	Green fluorescent protein	PD1	Programmed cell death protein 1
GO	Graphene oxide	PE	Prime editing
gRNA	Guide RNA	pDNA	Plasmid DNA
		PEG	Polyethylene glycol
		PEI	Polyethyleneimine
		pegRNA	PE gRNA
		PHx	Partial hepatectomy
		PLK1	Polo like kinase 1
		Psck9	Proprotein convertase subtilisin-like/kexin type 9
		Pten	Phosphatase and tensin homolog
		PTT	Photothermal therapy
		RCA@NP	sgRNA/Cas9/antisense-nanoparticle
		RNP	Ribonucleoprotein
		RPE	Retinal pigmented epithelium
		RPSA	Ribosomal protein SA

SaCas9	<i>Staphylococcus aureus</i> Cas9
SARS-CoV-2	Severe acute respiratory syndrome coronavirus 2
SHERLOCK	Specific high-sensitivity enzymatic reporter unlocking
SMOF	Ailicon-MOF
SORT	Selective organ targeting
ssDNA	Single-stranded DNA
SpCas9	<i>Streptococcus pyogenes</i>
TA	Tibialis anterior
tracrRNA	Transactivating crRNA
Ttr	Transthyretin
TYMP	Thymidine phosphorylase
VEGFR2	Vascular endothelial growth factor receptor 2
WNT10B	Wnt family member 10B
ZIF-8	Zeolitic imidazolate framework-8.

Author contributions

Muhammad Waseem Ghani perceived the conceptualization and wrote the original draft. Ambreen Iqbal helped in figure preparation and writing – review and editing. Hammad Ghani and Sidra Bibi helped in reviewing figures and writing – review and editing. Zixun Wang participated in conceptualization, writing – review and editing, and supervision. Renjun Pei acquired funding, helped with writing – review and editing, and supervised the manuscript preparation.

Conflicts of interest

The authors declare no conflict of interest.
