## Fe–N<sub>x</sub> sites coupled with Fe<sub>3</sub>C on porous carbon from plastic wastes for oxygen reduction reaction†

 Xiaole Jiang,<sup>‡a</sup> Rui Zhang,<sup>‡a</sup> Qingqing Liao,<sup>a</sup> Hanjun Zhang,<sup>a</sup> Yaoyue Yang<sup>ib</sup><sup>a</sup> and Fan Zhang<sup>ib</sup><sup>\*b</sup>

**Isolated Fe–N<sub>x</sub> sites coupled with Fe<sub>3</sub>C nanoparticles co-embedded in N-doped porous carbon were fabricated using polyethylene terephthalate wastes as carbon sources. Benefiting from the synergistic effect between Fe–N<sub>x</sub> sites and Fe<sub>3</sub>C, and the hierarchical porous structure, the catalyst exhibits outstanding ORR performance, realizing the concept of turning trash into treasure.**

Nowadays, polyethylene terephthalate (PET) is extensively used in applications such as food and beverage packaging. Global PET demand is forecasted to rise to 22.65 million tonnes by 2025.<sup>1</sup> Unfortunately, the production of PET consumes a lot of fossil resource, and the low biodegradability of PET contributes to the accumulation of plastic waste, causing severe threats to the energy demand and natural ecosystem.<sup>2–4</sup> At the same time, the incineration of PET wastes can lead to significant air pollution.<sup>1,3</sup> Therefore, developing sustainable and efficient strategies to recycle PET waste into value-added products is imperative. Considering the significant carbon content in plastic wastes, PET wastes have been regarded as sustainable carbon resources for synthesizing carbon nanomaterials.<sup>4–7</sup> Tang *et al.* efficiently converted waste PET bottles into porous carbon nanosheets (PCNS) by combining catalytic carbonization and the KOH activation process. The obtained PCNS displayed outstanding capability in double-layer supercapacitors of 169 F g<sup>−1</sup> in 6 M KOH.<sup>4</sup> Zhang *et al.* transformed PET wastes into N-doped carbon sheets (LPNCS) as carriers to disperse Ru nanoparticles. The Ru/LPNCS displayed outstanding HER performance with a low overpotential (15 mV@10 mA cm<sup>−2</sup>).<sup>6</sup> Despite these advances,

carbon materials derived from PET wastes for oxygen reduction reaction (ORR) have rarely been reported.

Developing sustainable energy conversion systems has been regarded as one promising strategy to alleviate the energy crisis and environmental pollution.<sup>8</sup> Zn–air batteries (ZABs) are drawing great attention owing to their high energy density, environment-friendliness, low cost, and high safety.<sup>9</sup> However, the energy conversion efficiency of ZABs is limited by the sluggish kinetics of the cathodic ORR.<sup>10</sup> Although platinum-group nanomaterials have demonstrated excellent ORR performance, their scarcity, high cost, and dissatisfactory stability heavily hindered their large-scale commercial application.<sup>11</sup>

Recently, atomically dispersed metal–nitrogen–carbon (M–N–C, M = Co, Fe, Ni, *etc.*) catalysts have held a promising performance for ORR.<sup>12,13</sup> However, achieving optimal catalytic activity with only isolated active sites is challenging due to the linear scaling relations between the adsorption/desorption toward complex multiple intermediate reactions.<sup>14</sup> Noteworthy, introducing some synergistic components, such as metal nanoparticles and metal sulfides adjacent to the isolated M–N<sub>x</sub> sites, has been proposed to regulate the adsorption/desorption energy barriers of reaction intermediates, thereby accelerating the ORR process.<sup>15–17</sup> Chen *et al.* successfully constructed a coupling catalyst with Fe–N<sub>4</sub> and FeS NPs embedded in N/S-doped porous carbon (FeS/FeNSC). The oxidized sulfur and FeS NPs synergistically modulated the electronic structure of Fe–N<sub>4</sub> sites, leading to outstanding ORR performance and superior stability.<sup>17</sup>

Herein, isolated Fe–N<sub>x</sub> sites coupled with Fe<sub>3</sub>C nanoparticles embedded in N-doped porous carbon were successfully fabricated by using PET wastes as a carbon source. The Fe<sub>3</sub>C/Fe–N–C catalyst possessed outstanding ORR performance, attributed to the synergistic effect between Fe<sub>3</sub>C nanoparticles and Fe–N<sub>x</sub> sites as well as the hierarchical porous structure. Specifically, it has an onset potential (*E*<sub>onset</sub>) of 0.99 V and a half-wave potential (*E*<sub>1/2</sub>) of 0.89 V (*vs.* RHE), respectively. Moreover, the Fe<sub>3</sub>C/Fe–N–C-based ZAB revealed a maximum power density of 211 mW cm<sup>−2</sup> and long discharge stability, indicating its

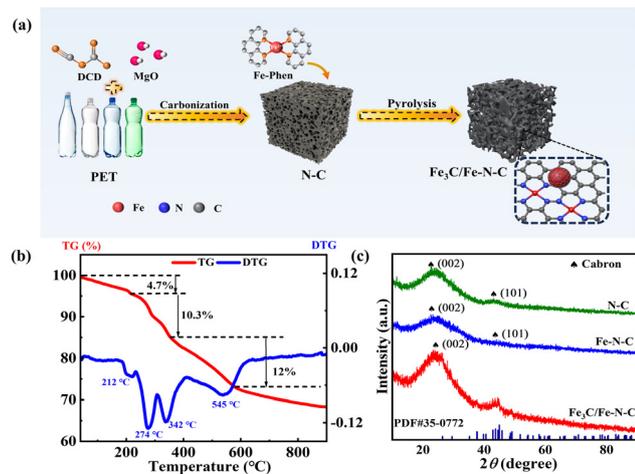

Fig. 1 (a) Schematic illustration for the synthesis of Fe<sub>3</sub>C/Fe-N-C catalyst. (b) TG and DTG curves of PET/MgO/DCD mixture under Ar atmosphere. (c) XRD patterns of N-C, Fe-N-C, and Fe<sub>3</sub>C/Fe-N-C catalysts.

potential for practical energy devices. This research not only demonstrates the reuse of plastic waste but also provides an effective catalyst for fuel cell/ZAB applications, contributing to the concept of converting waste into valuable resources.

The facile synthesis process of the Fe<sub>3</sub>C/Fe-N-C catalyst is depicted in Fig. 1a. Typically, N-doped porous carbon was synthesized from the cost-effective carbon source of PET wastes *via* the MgO-templated method. Subsequently, the Fe-phenanthroline (Fe-Phen) was anchored on the porous carbon *via* the incorporation method. Finally, the Fe-Phen/N-C mixture was converted into isolated Fe-N<sub>x</sub> sites coupled with Fe<sub>3</sub>C nanoparticles embedded in N-doped porous carbon after pyrolysis. The carbonization process of the PET mixture was investigated by thermogravimetric analysis (TGA). As shown in Fig. 1b, the pyrolysis of the PET/MgO/cyanoguanidine (DCD) mixture displays four stages. The first stage involves heating from room temperature to 208 °C with a weight loss of 4.7 wt% due to the evaporation of the DCD. The weight loss in the second and third stages (212 to 342 °C) is attributed to the decomposition of DCD.<sup>18,19</sup> Following this, there is a 12 wt% weight loss, which corresponds to the PET carbonation and the formation of N-doped carbon.<sup>6</sup> The XRD patterns of all the synthesized catalysts are displayed in Fig. 1c. Only two diffraction peaks at 23.9° and 43.4° belonged to the C (002) and (101) planes can be observed in N-C and Fe-N-C catalysts,<sup>20</sup> indicative of the absence of Fe-based particles in Fe-N-C catalyst. In contrast, the XRD pattern of Fe<sub>3</sub>C/Fe-N-C exhibits additional diffraction peaks assigned to Fe<sub>3</sub>C (PDF#35-0772), implying the formation of Fe<sub>3</sub>C with increasing pyrolysis temperature.<sup>14</sup>

The morphology and microstructure of the catalysts were observed by scanning electron microscopy (SEM) and transmission electron microscopy (TEM). As displayed in Fig. 2a and Fig. S1a, b (ESI<sup>†</sup>), similar 3D interconnected architecture is observed for all the catalysts, and the HRTEM images (Fig. 2b and Fig. S1c-f, ESI<sup>†</sup>) reveal that 3D carbon structure is assembled by interconnected porous nanosheets. Furthermore, the HRTEM

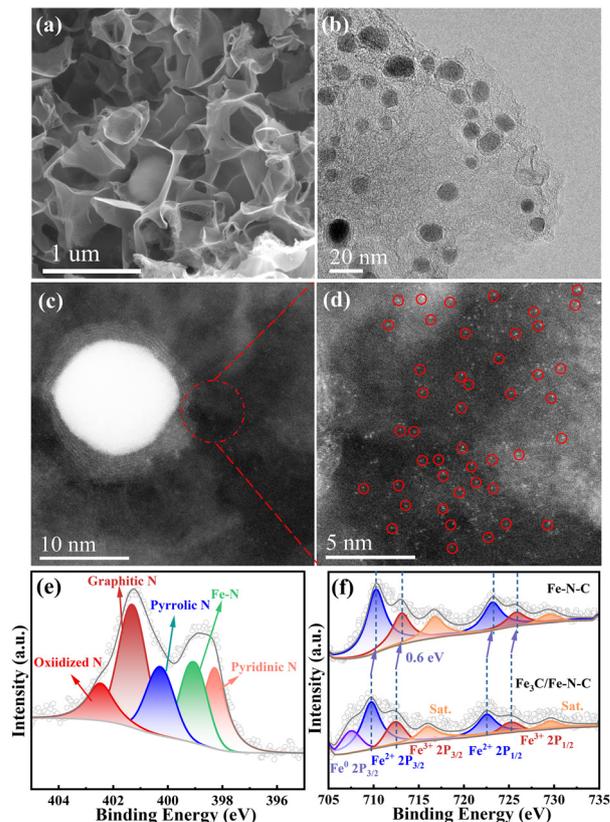

Fig. 2 (a) SEM and (b) HRTEM images of Fe<sub>3</sub>C/Fe-N-C. (c) and (d) HAADF-STEM images of Fe<sub>3</sub>C/Fe-N-C (isolated Fe sites are highlighted by the red circles). (e) High-resolution N 1s spectra of Fe<sub>3</sub>C/Fe-N-C. (f) Fe 2p XPS spectra of the Fe-N-C and Fe<sub>3</sub>C/Fe-N-C.

images of the Fe-N-C catalyst (Fig. S1d and f, ESI<sup>†</sup>) confirm the absence of metal nanoparticles, which agrees with the XRD results. The HAADF-STEM images (Fig. S2, ESI<sup>†</sup>) show that abundant bright spots are uniformly dispersed in the carbon substrate, indicating that Fe species are present as isolated Fe atoms. For comparison, large amounts of iron-based nanoparticles with a size of 5–20 nm encapsulated by a few-layer graphitized carbon shell can be observed in Fe<sub>3</sub>C/Fe-N-C catalyst (Fig. 2b). Meanwhile, as displayed in Fig. S3a (ESI<sup>†</sup>), the lattice distance of the nanoparticle is 0.197 nm, corresponding to the (112) plane of Fe<sub>3</sub>C.<sup>21,22</sup> Additionally, the HAADF-STEM images (Fig. 2c and d) reveal that abundant isolated Fe atoms (bright spots) distributed around the Fe<sub>3</sub>C nanoparticle, confirming the coexistence of atomically dispersed Fe-N<sub>x</sub> sites and Fe<sub>3</sub>C. Moreover, energy-dispersive X-ray (EDX) elemental mappings confirm the homogeneous distribution of C, N, and Fe in the Fe<sub>3</sub>C/Fe-N-C catalyst (Fig. S3b, ESI<sup>†</sup>).

The Raman spectra of all the catalysts display two typical peaks at 1344 and 1581 cm<sup>-1</sup>, attributed to the defects carbon (D band) and the graphitic carbon (G band), respectively. As shown in Fig. S4 (ESI<sup>†</sup>), the D to G band intensity ratio (*I<sub>D</sub>*/*I<sub>G</sub>*) of Fe-N-C (1.08), Fe<sub>3</sub>C/Fe-N-C (1.00), and N-C (1.17) have no obvious difference.<sup>16,23</sup> The isotherms curves of N-C, Fe-N-C,

and Fe<sub>3</sub>C/Fe-N-C exhibit apparent adsorption at the low-pressure region and a typical hysteresis loop, indicating the coexistence of micropores and mesopores (Fig. S5, ESI†). The BET surface areas were calculated to be 444, 427, and 480 m<sup>2</sup> g<sup>-1</sup> for N-C, Fe-N-C, and Fe<sub>3</sub>C/Fe-N-C catalysts, respectively (Table S1, ESI†). Besides, the pore-size distribution reveals that mesopores with diameters ranging from 3–35 nm are predominantly presented in Fe-N-C and Fe<sub>3</sub>C/Fe-N-C. The high surface area and hierarchical porous structure would be beneficial for exposing active sites and enhancing mass transport during the ORR process.<sup>9</sup>

The surface chemical state and compositions of all the catalysts (Table S2, ESI†) were analyzed by X-ray photoelectron spectroscopy (XPS). The high-resolution N 1s spectra of all the catalysts (Fig. 2e and Fig. S6, ESI†) confirmed the presence of pyridinic-N (~398.2 eV), Fe-N (~399.02 eV), pyrrolic-N (~400.03 eV), graphitic-N (~401.05 eV) and oxidized-N (~402.22 eV).<sup>24</sup> The Fe 2p XPS spectrum (Fig. 2f) for Fe-N-C displays six peaks at 710.31, 723.16 eV, 712.99, and 725.79 eV, which correspond to Fe 2p<sub>1/2</sub> and Fe 2p<sub>3/2</sub> orbitals of Fe<sup>2+</sup> and Fe<sup>3+</sup> as well as a pair of satellite peaks. Notably, apart from the oxidized Fe species, a peak at 707.4 eV belonging to Fe<sup>0</sup> (originating from Fe<sub>3</sub>C) is detected for the Fe<sub>3</sub>C/Fe-N-C catalyst.<sup>25,26</sup> Meanwhile, the binding energies of Fe<sup>2+</sup> and Fe<sup>3+</sup> in Fe<sub>3</sub>C/Fe-N-C catalyst negatively shift by 0.6 eV compared with those of Fe<sub>3</sub>C/Fe-N-C, implying the electronic interactions between Fe-N<sub>x</sub> and Fe<sub>3</sub>C nanoparticles.<sup>17,27</sup>

The ORR activities of the as-synthesized catalysts and commercial Pt/C (40 wt%) were evaluated in the O<sub>2</sub>-saturated 0.1 M KOH solution. As shown in Fig. 3a, Fe<sub>3</sub>C/Fe-N-C displays the best ORR catalytic performance. In detail, the  $E_{\text{onset}}$  and  $E_{1/2}$  are significantly enhanced from N-C to Fe-N-C catalysts, indicating that the Fe-N<sub>x</sub> active sites boost the ORR catalytic activity. The Fe<sub>3</sub>C/Fe-N-C catalyst presents the most positive  $E_{\text{onset}}$  of 0.99 V (vs. RHE) and  $E_{1/2}$  of 0.89 V, superior to those of Fe-N-C ( $E_{\text{onset}}$  = 0.94 V,  $E_{1/2}$  = 0.86 V), and Pt/C ( $E_{\text{onset}}$  = 0.94 V,  $E_{1/2}$  = 0.83 V) catalysts. Note that the outstanding ORR activity of Fe<sub>3</sub>C/Fe-N-C compared to Fe-N-C could be ascribed from the introduction of Fe<sub>3</sub>C NPs, indicating that the electronic structure of Fe-N<sub>x</sub> sites is tuned by the Fe<sub>3</sub>C NPs and their synergistic effect significantly boosts the ORR process.<sup>15,17</sup> Furthermore, the Fe<sub>3</sub>C/Fe-N-C catalyst presents the lowest Tafel slope (57.76 mV dec<sup>-1</sup>), and even lower than 69.42 mV dec<sup>-1</sup> of Pt/C, implying its faster kinetics (Fig. 3b). The kinetic current density ( $J_k$ ) at 0.85 V of Fe<sub>3</sub>C/Fe-N-C catalyst is 23.68 mA cm<sup>-2</sup>, which is much superior to those of Fe-N-C (7.18 mA cm<sup>-2</sup>) and Pt/C (3 mA cm<sup>-2</sup>) catalysts (Fig. 3c). To investigate the reaction pathways, RRDE tests were conducted on all the catalysts. As shown in Fig. 3d, the H<sub>2</sub>O<sub>2</sub> yield of Fe<sub>3</sub>C/Fe-N-C is below 12%, obviously smaller than those of N-C and Fe-N-C. The electron transfer number ( $n$ ) of the Fe<sub>3</sub>C/Fe-N-C catalyst reaches 3.9, which is further confirmed by the number obtained from the K-L plot (Fig. S7, ESI†), indicating that the 4 e<sup>-</sup> pathway occurred on the Fe<sub>3</sub>C/Fe-N-C catalyst.<sup>28</sup> Thus, the Fe<sub>3</sub>C/Fe-N-C catalyst outperforms all other reported catalysts derived from plastic wastes and is

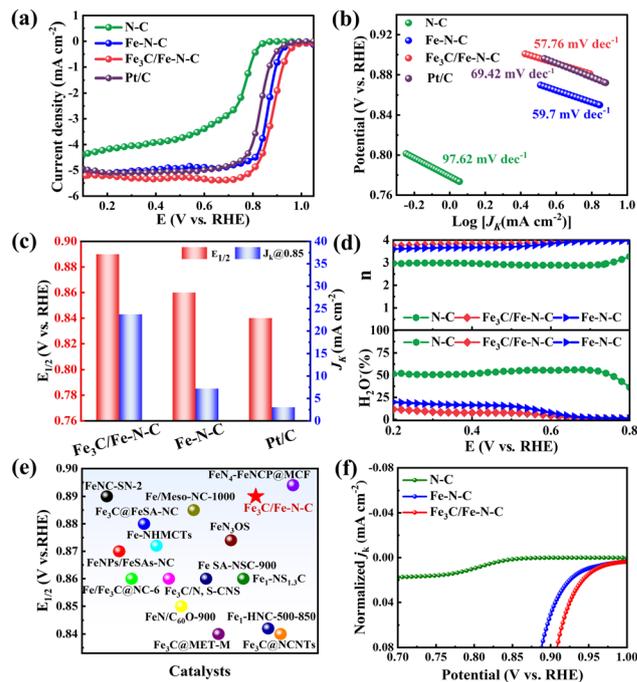

Fig. 3 (a) LSV curves of different catalysts in O<sub>2</sub> saturated 0.1 M KOH. (b) Tafel slopes of different catalysts. (c)  $E_{1/2}$  and  $J_k$  of all the catalysts. (d) The H<sub>2</sub>O<sub>2</sub> yields and electron transfer numbers of the catalysts. (e) Based on  $E_{1/2}$ , performance comparison of different catalysts. (f) Normalized  $J_k$  by ECSA for N-C, Fe-N-C, and Fe<sub>3</sub>C/Fe-N-C.

comparable to other state-of-the-art Fe-based ORR catalysts (Fig. 3e and Table S3, ESI†).

The durability and methanol tolerance are significant for the practical application of electrocatalysts. As depicted in Fig. S8 (ESI†), the Fe<sub>3</sub>C/Fe-N-C catalyst exhibits 82% retention of the initial current after 40 000 s, while the Pt/C catalyst retained only 70%. Furthermore, the Fe<sub>3</sub>C/Fe-N-C catalyst maintains a stable current after the injection of methanol into the electrolyte. In contrast, the current of the Pt/C significantly decreases, indicative of the excellent methanol tolerance of the Fe<sub>3</sub>C/Fe-N-C catalyst. These results suggest that Fe<sub>3</sub>C/Fe-N-C catalyst exhibits promising potential for applications in fuel cells.

To gain deep insights into the origin of excellent ORR performance, the electrochemical active surface area (ECSA) is calculated from the double-layer capacitance ( $C_{dl}$ ), which is obtained from the cyclic voltammetry curves in the non-faradaic potential region.<sup>24</sup> As shown in Fig. S9 (ESI†), the  $C_{dl}$  values of N-C, Fe-N-C and Fe<sub>3</sub>C/Fe-N-C are 20.5, 9.3 and 12.2 mF cm<sup>-2</sup>, respectively. Furthermore, the  $J_k$  of all the catalysts was normalized by the ECSA. The normalized  $J_k$  curves consistently showed a similar trend to the LSV curves. This suggests that the enhanced catalytic activity of Fe-N-C and Fe<sub>3</sub>C/Fe-N-C compared to N-C is primarily attributed to the improved intrinsic activity stemming from the Fe species rather than the effect of the electrochemical active surface area.<sup>17</sup> As it is widely recognized that SCN<sup>-</sup> can deactivate the Fe-N<sub>x</sub> sites, we conducted a KSCN poisoning experiment to confirm the active sites.<sup>15</sup> As depicted in Fig. S10 (ESI†), the  $E_{1/2}$  of Fe-N-C and

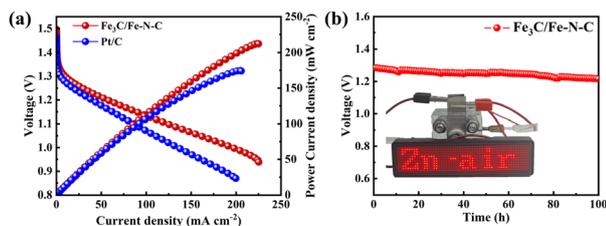

Fig. 4 (a) Discharging polarization and power density curves of  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  and  $\text{Pt/C}$ . (b) Corresponding discharging curves at  $10 \text{ mA cm}^{-2}$  of the  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  based ZAB (photograph of an LED panel lighted up by  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  based ZAB).

$\text{Fe}_3\text{C}/\text{Fe-N-C}$  significantly decrease after adding 20 mM KSCN into the electrolyte, suggesting that the isolated  $\text{Fe-N}_x$  sites are the main ORR active sites, which agrees with the previous reports.<sup>13,15</sup> Combined with the above results, the coexistence of  $\text{Fe}_3\text{C}$  NPs and atomically dispersed  $\text{Fe-N}_x$  sites play an important role in improving the ORR performance of  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  catalyst.

To further explore the practical applications of the  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  catalyst, we assembled a ZAB using catalyst-loaded carbon paper as the cathode, zinc foil as the anode, and a 6 M KOH with 0.2 M zinc acetate solution as the electrolyte, respectively. As exhibited in Fig. 4, the open-circuit potential of  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  based ZAB is 1.5 V, which is higher than that of the  $\text{Pt/C}$ -based counterpart (1.44 V). Additionally, the  $\text{Fe}_3\text{C}/\text{Fe-N-C}$ -based ZAB delivers a maximum power density of  $211 \text{ mW cm}^{-2}$ , outperforming the  $\text{Pt/C}$ -based ZAB ( $174 \text{ mW cm}^{-2}$ ) and most of the reported carbon-based catalysts (Table S3, ESI<sup>†</sup>). The  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  based battery displays a stable discharge platform during 100 hours at  $10 \text{ mA cm}^{-2}$ , indicating the outstanding stability of  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  catalyst for practical application in ZAB (Fig. 4b). Meanwhile, our ZAB could provide sufficient power to energize a light-emitting diode (Fig. 4b).

In summary, a simple and facial strategy has been proposed to synthesize atomically dispersed  $\text{Fe-N}_x$  sites and  $\text{Fe}_3\text{C}$  nanoparticles coexistence in N-doped porous carbon ( $\text{Fe}_3\text{C}/\text{Fe-N-C}$ ) by using low-cost PET waste as the carbon precursor. The  $\text{Fe}_3\text{C}/\text{Fe-N-C}$  catalyst exhibited outstanding ORR performance and superior durability in alkaline media, owing to the synergistic effect between  $\text{Fe-N}_x$  sites and  $\text{Fe}_3\text{C}$  nanoparticles, as well as the hierarchical porous structure. Our work not only offers an effective way to recycle PET wastes into “gold electrocatalyst” but also sheds light on the precise design of high-performance ORR catalysts with tunable electronic configurations.
