# Unveiling the quantum secrets of triel metal triangles: a tale of stability, aromaticity, and relativistic effects†

Sílvia Escayola, obab Elisa Jimenez-Izal, obac Eduard Matito, obab Jesus M. Ugalde, bc Rafael Grande-Aztatzi state and Jose M. Mercero \*\*

Low lying electronic states of  $Al_3^-$ ,  $Ga_3^-$ ,  $In_3^-$ , and  $Tl_3^-$  have been characterized using high level multiconfigurational quasi degenerate perturbation theory on the multiconfigurational self-consistent field. Among these species, the singlet  ${}^{1}A_{1}^{\prime\prime}$  states emerge as the predominant energy minima, displaying remarkable stability. However, within the Tl<sub>3</sub><sup>-</sup> series, our investigation leads to the identification of the high-spin  ${}^5A_1''$ , as the most stable spin state, a result corroborated by previous experimental detection via photoelectron spectroscopy. Similarly, we have also identified the singlet state of  $In_3^-$  as the signal detected previously experimentally. By applying Mandado's rules and an array of aromaticity indicators, it is conclusively demonstrated that both the singlet and quintet states exhibit multiple-fold aromaticity, while the triplets exhibit conflicting aromaticity. Furthermore, this investigation highlights the significant impact of relativistic effects, as they enhance the stability of the  ${}^5A_{1}^{\prime\prime}$ -TI<sub>3</sub><sup>-</sup> state relative to its singlet counterpart. These findings shed new light on the electronic structures and properties of these ions, offering valuable insights into their chemical behavior and potential applications.

#### 1 Introduction

Al<sub>3</sub> triangles have widely been studied theoretically and experimentally, in both the ground state and excited states. 1-10 However, its anionic form Al<sub>3</sub><sup>-</sup> has been studied to a lesser extent. The first study of Al<sub>3</sub><sup>-</sup> we have found in the literature was conducted by H. Basch.1 He calculated the electronic properties of the anion using MCSCF methods, and a  $C_{2v}$ symmetry triangle was reported as the ground state. Later, Taylor et al. and Ganteför et al. studied Al<sub>3</sub> using photoelectron spectroscopy. <sup>11,12</sup> In 1995, Calaminici et al. <sup>2</sup> reported a  $D_{3h}$ triangle as the singlet ground state using DFT. In 1998, Baeck and Bartlet<sup>3</sup> characterized the low-lying electronic states of Al<sub>3</sub> using the CCSD(T), confirming an equilateral triangle as the ground state  $({}^{1}A'_{1})$ .

A few years later, Kuznetsov and Boldyrev<sup>13</sup> extended the allmetal aromaticity concept to the Al<sub>3</sub><sup>-</sup> and Ga<sub>3</sub><sup>-</sup> anions, describing both triangles as  $\pi$ -aromatic systems. Later on, Zhan et al. pointed out that the  $Al_3$  triangle was not just  $\pi$ -aromatic, <sup>14</sup> and introduced the idea of multiple-fold aromaticity, showing a two-fold aromatic system,  $\pi$ - and  $\sigma$ -aromatic. In 2009, Villalta and Leopold,5 experimentally characterized both the ground and excited states of Al<sub>3</sub> and Al<sub>3</sub> trimers, confirming the <sup>1</sup>A<sub>1</sub> state as the ground state. These experimental results were rationalized with single-reference DFT and coupled cluster methods by Miller et al.4

In 2015, we described the lowest-lying electronic states of the Al<sub>3</sub><sup>-</sup> triangle using DFT and multiconfigurational high-level calculations supplemented with quasi-degenerated perturbation theory.15 We showed that not only the ground state, but the triplet and quintet excited states were aromatic. Recently, Al<sub>3</sub><sup>-</sup> aromaticity was analyzed by means of the natural orbital functional (NOF) theory.16

Ga<sub>3</sub>, In<sub>3</sub>, and Tl<sub>3</sub> trimers have also been previoulsy studied. Pöttgen and coworkers have characterized many crystal structures where Al<sub>3</sub>, <sup>17</sup> Ga<sub>3</sub>, <sup>18-21</sup> and In<sub>3</sub>, <sup>22-24</sup> triangles are present, and there are many other similar structures reported in the literature. 25-27 Some molecules where Ga3 triangles are identified have also been synthesized. 28-31 Theoretical investigations are also available for Ga<sub>3</sub> and In<sub>3</sub> in the literature. <sup>32–38</sup> Among all these studies, only a few have focused on triangular anions.

**Paper PCCP** 

In 1990, Meier et al.<sup>33</sup> studied Ga<sub>3</sub> using MRD-CI techniques; few years later, in 1994, Cha et al.39 obtained the photoelectron spectra for Ga<sub>3</sub><sup>-</sup>. In 2002, Kuznetsov and Boldyrev, <sup>13</sup> described the aromaticity of the Ga<sub>3</sub>-. There is a limited number of research works dedicated to the investigation of In<sub>3</sub>-. Gausa et al. performed photoelectron spectroscopy experiments for  $In_n^-$  and  $Tl_n^-$  clusters. 36 The studies regarding the  $Tl_3$  are scarce, including those by Gausa et al. and Vijayakumar et al., 40 who used MCSCF methods to characterize Tl<sub>3</sub>+/- molecules, while Kang<sup>41</sup> described the Tl<sub>3</sub><sup>+</sup> triangle in 1993, and Tsipis et al. discussed NICS evolution in different compounds including the Tl<sub>3</sub><sup>-</sup>.<sup>42</sup>

The manuscript at hand employees multiconfigurational self-consistent methods to investigate X<sub>3</sub><sup>-</sup> triangles, (where X= Al, Ga, In, and Tl), exploring several properties of the lowest-energy spin states. The study establishes a connection between the experimentally measured photoelectron spectra and the <sup>1</sup>A<sub>1</sub>' state of In<sub>3</sub><sup>-</sup> and <sup>5</sup>A<sub>2</sub>" state of Tl<sub>3</sub><sup>-</sup>. Additionally, the aromaticity of the complexes is analyzed using the multicenter index (MCI) and its  $\pi$ -fraction (MCI $_{\pi}$ ) across different electronic configurations to demonstrate the multiple-fold aromaticity determined by the independent delocalized  $\sigma$  and  $\pi$  bonding systems. The study also employs delocalization indexes<sup>43,44</sup> (DI) and adaptive natural density partitioning analysis 45 (AdNDP) to obtain an alternative perspective and quantify the aromaticity, and finally, a magnetic criteria is also used, the iso-chemicalshielding surfaces<sup>46,47</sup> (ICSS) method.

#### 2 Methods

State-specific multiconfigurational self consistent field (MCSCF)<sup>48</sup> complemented by multiconfigurational quasi-degenerate perturbation (MCQDPT)<sup>49</sup> methods have been employed to characterize the electronic structure of the different X<sub>3</sub> (X= Al, Ga, In and Tl) triangles by using the Karlsruhe Def2-TZVPPD50,51 basis set wich includes pseudopotentials for In<sup>52</sup> and Tl.<sup>53</sup> Inconsistencies caused by the so-called intruder states, which appear when the perturbation expansion of the reference MCSCF wave function has vanishingly small energy denominators, were remedied by shifting them by 0.02 a.u., as recommended earlier.<sup>54</sup> The vibrational frequencies were also calculated at the MCSCF level of theory. The ten valence electrons of the system were included in the active space, which were allowed to distribute themselves in twelve molecular orbitals (MO) (full active space). The selected twelve orbitals are the ones depicted in Fig. 1 and encompass the different-fold aromatic systems as described with elegant simplicity by Dixon et al.14 spin-orbit coupling where estimated using the Pauli-Breit approximation for the coupling Hamiltonian, at the aforementioned level of theory as implemented in the GAMESS US program.55

The aromaticity of the characterized triangular systems has been assessed by means of different analysis tools, multicenter index (MCI),<sup>56</sup> adaptive natural density partitioning (AdNDP)<sup>45</sup> and the iso-chemical-shielding surfaces (ICSS) method. 46,47 Although these tools are all used to measure the aromaticity

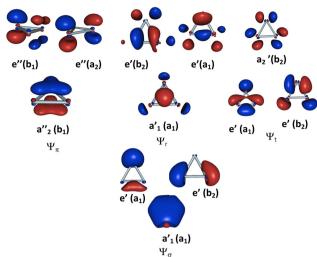

Fig. 1 MCSCF(10,12) natural orbitals (NOs) of the Al<sub>3</sub><sup>-</sup> grouped in the four aromatic independent systems,  $\Psi_{\sigma}$ ,  $\Psi_{\pi}$ ,  $\Psi_{r}$  and  $\Psi_{t}$ ,  $\sigma$ ,  $\pi$ , radial and tangential, respectively. The orbitals for the singlet and the quintet are similar, while, despite of the symmetry change to  $C_{2v}$ , the triplet structures triangles maintain a similar form ( $C_{2v}$  symmetry equivalent labels are given in parentheses).

in molecules, they differ in their methods. MCI quantifies the degree of magnetic circuit delocalization in a molecule by integrating the magnetic flux density along a closed loop that passes through the aromatic ring, AdNDP uses a natural orbital-based partitioning scheme to analyze electron density by partitioning it into natural orbitals. In conclusion, these methods can be used together to provide a more comprehensive understanding of the electron delocalization in a molecule. MCI and DI have been calculated using the ESI-3D program, 44,57 and were computed for all the isomers using their corresponding MCSCF (10,12) wave functions. The atomic overlap matrices, required by ESI-3D to calculate the MCIs, were obtained from the APOST-3D<sup>58</sup> software using the topological fuzzy Voronoi (TVFC) cell partition. <sup>59-61</sup> To account for the numerical errors in APOST-3D and ESI-3D, we verified that the number of electrons was equal to the sum of all the electron populations of the molecule, the error being always below

AdNDP and ICSS analysis were carried out at the CAM-B3LYP/Def2-TZVPP level of theory. ICSS method was used via Multiwfn code.62

#### 3 Results

In this manuscript, we will explore the various properties of the lowest-energy spin states, namely,  ${}^{1}A'_{1}$ ,  ${}^{3}B_{2}$  and  ${}^{5}A''_{2}$ , of the  $X_{3}^{-}$ (where X = Al, Ga, In, and Tl) triangles. The geometries of these structures were optimized at the MCSCF (10,12) level, and their energies were refined at the MCQDPT level of theory. Our results exhibit a substantial multireference character for these structures. The <sup>1</sup>A<sub>1</sub> ground states are mainly dominated by the  $(a_2'')^2(a_1')^2$  single reference state (with a configuration

**PCCP** Paper

interaction coefficient (CIC) of around 0.9, see Table S3 in ESI† for the main CICs of the different molecules states), with significant contributions from each of the two configurations featuring degenerate orbitals  $(a_2'')^2(e')^2$  and  $(a_1')^2(e')^2$ , both with identical CIC coefficients (note that the other six electrons are in the  $\Psi_{\sigma}$  system, see Fig. 1). The  ${}^{3}B_{2}$  states main configuration is the  $(b_1)^2(a_1)^1(b_2)^1$  with a CIC around 0.88. Lastly, the quintets exhibit the smallest multiconfigurational character, with the  $(a_2'')^1(a_1')^1(e')^1(e')^1$  configuration being dominant, with a CIC around 0.92.

As previously reported in the literature, 63,64 the aluminum trimers possess four independent MO sets derived from the s-type and p-type atomic orbitals (AO) (Fig. 1). The  $\Psi_{\sigma}$  set is formed by the three s-AOs, the three  $p_z$ -AOs form the  $\Psi_{\pi}$ , the p orbitals oriented in the radial direction form the  $\Psi_r$  (radial) set, and p-orbitals oriented in the tangential direction the  $\Psi_t$ (tangential) (see Fig. 1). These group-13 X<sub>3</sub><sup>-</sup> triangles possess a valence shell of ten electrons, six of which are located in the  $\Psi_{\sigma}$  orbitals, and the remaining four are arranged in four orbitals with similar energies. We observed the same MO sets in all the complexes studied.

Table 1 presents a summary of the geometrical, energetic, and aromaticity properties obtained for the lowest-lying energy spin-states of the  $X_3$  (X = Al, Ga, In and Tl) triangles. The  ${}^3A_1$ , <sup>3</sup>A<sub>2</sub>, and <sup>3</sup>B<sub>1</sub> states were also characterized, but they were found to be higher in energy than the 3B2, and in the interest of

Table 1 Calculated properties of the lowest-energy spin-states of the X<sub>3</sub> triangles (where X = Al, Ga, In, and Tl). Symm. stands for the symmetry of the molecule, the values of  $\Delta E$  are ZPE-corrected MCQDP/MCSCF (10,12) relative energies, expressed in kcal mol<sup>-1</sup> with respect to the singlet state. R represents the equilibrium bond lengths of the triangles in Å. Note that 1, 2, and 3 refer to the atom numbers, so  $R_{1,2}^{1,3}$  means that the bond length between atoms 1 and 2, and 1 and 3 is the same, and  $R_{2,3}$  corresponds to the distance between atoms 2 and 3. This situation corresponds to  $C_{2\nu}$ symmetry. However, it is important to recall that for  $D_{3h}$  molecules,  $(R_{1,2}^{1,3})$ and  $R_{2,3}$  are equal. The same applies to  $\delta$ , the atom-pair (determined by the sub and super indexes) DI, where, in the triplets,  $\delta_{1.3}^{1.2}$  stands for the equalsize atom-pair DI, and  $\delta_{2,3}$  to the longer size atom-pair. The total multicenter index (MCI) is also reported along with its  $\pi$  contribution to the aromaticity (MCI,,)

brevity, we will focus only on the lowest state, although the details of the <sup>3</sup>A<sub>1</sub>, <sup>3</sup>A<sub>2</sub>, and <sup>3</sup>B<sub>1</sub> states can be found in the ESI<sup>†</sup>

Upon analyzing the outcomes, it is evident that Al<sub>3</sub> and Ga<sub>3</sub> not only have a similar size but also exhibit comparable energy differences between different electronic states. Specifically, there is a difference of approximately 7 kcal mol<sup>-1</sup> in energy for the <sup>3</sup>B<sub>2</sub> state and 12 kcal mol<sup>-1</sup> for the <sup>5</sup>A<sub>2</sub>" state, with respect to the singlets. Conversely, the In<sub>3</sub><sup>-</sup> ion is found to be significantly larger in size, and the energy differences between electronic states are reduced to 2.54 and 3.20 kcal  $\text{mol}^{-1}$  for the triplet and quintet states with respect to the singlet. Importantly, for Tl<sub>3</sub><sup>-</sup>, the picture changes, with the quintet being the most stable electronic state followed by the triplet and the singlet, which are around 2.2 and 2.9 kcal mol<sup>-1</sup> higher in energy, respectively. Additionally, spin-orbit couplings were measured and found to be small, smaller than 5 cm<sup>-1</sup>.

Intrigued by the fact that the quintet spin state is the most stable electronic state of Tl<sub>3</sub><sup>-</sup>, vertical detachment energy (VDE) energy calculations were performed to compare them with the photoelectron spectrum reported by Gausa et al. 36 Such spectrum exhibited three primary signals, one at 1.5 eV, another at 1.7 eV, and the third around 2.2 eV. We conducted MCQDPT VDE calculations beginning from the <sup>5</sup>A<sub>1</sub> state, which yielded two degenerated VDEs of 1.30 eV, corresponding to detachment of the e' electrons, another of 1.66 eV for the detachment of the  $a_2''$  electron, and the fourth of 1.77 eV for the  $a_1'$  electron. We also performed partial third-order quasiparticle theory<sup>65</sup> (P3) electron propagator calculations (as implemented in Gaussian 16<sup>66</sup>), which resulted in VDEs of 1.52, 1.76, and 2.12 eV for the quintet, corresponding to e',  $a''_2$ , and  $a'_1$  electron detachments, respectively. Based on our calculations, we can conclude that the experimentally detected signal corresponds to the quintet electronic state of the Tl<sub>3</sub><sup>-</sup> molecule.

We also calculated the VDE's for In<sub>3</sub><sup>-</sup> and compared it to the photoelectron spectrum measured by Gausa et al. 36 The experimental spectrum exhibited two primary signals, one around 1.65 eV and the other around 1.85 eV. Our MCQDPT calculations resulted in VDEs of 1.70 eV and 1.74 eV, which are consistent with the experimentally measured signals. Additionally, using the Partial Third-order quasiparticle theory<sup>65</sup> (P3) electron propagator, we obtained VDEs of 1.69 eV and 1.85 eV, in excellent agreement with the experimental signals. Therefore, it is inferred that the detected signals correspond to the  ${}^{1}A'_{1}$  electronic state of  $In_{3}^{-}$ .

The results for Al<sub>3</sub><sup>-</sup> and Ga<sub>3</sub><sup>-</sup> are consistent with previous theoretical and experimental findings. Villalta et al. experimentally identified a triplet excited state with an obtuse  $(C_{2y})$ symmetry) triangle geometry, <sup>3</sup>B<sub>2</sub> electronic configuration and  $9.43 \text{ kcal mol}^{-1}$  higher in energy than the singlet state. Two sides of the triangle have equal lengths, similar to those of the ground state, while the third side is 0.187 Å larger. Our highlevel ab initio calculations, as shown in Table 1, are in excellent agreement with their experimental results.5

Note that our calculations indicate highly correlated electronic structures for all the systems considered. However, there is Paper

excellent agreement between our results and those obtained from DFT/CCSD(T)4 and CCSD(T)3 calculations, as well as with experimental counterparts.<sup>5</sup>

It is noteworthy that the quintet state is the most stable electronic state for Tl<sub>3</sub><sup>-</sup>, which is in contrast to the well-studied case of Al<sub>3</sub><sup>-</sup>, where the singlet state is the most stable and exhibits the highest aromaticity when compared with the 3B2 and <sup>5</sup>A<sub>2</sub>" states. We have analyzed the aromaticity of Tl<sub>3</sub><sup>-</sup> and compared it with that of the Al<sub>3</sub><sup>-</sup> triangle, to unveil its effect on the stability of the Tl<sub>3</sub><sup>-</sup>.

Aromaticity is a concept that lacks a precise definition and does not correspond to any measurable physical property. As a result, it is difficult to identify a specific property that can determine aromaticity. 67-69 To address this challenge, numerous indicators have been developed, including the multicenter index  $(MCI)^{56}$  and the  $I_{ring}^{70}$  multicenter index, which are among the most reliable indicators for small systems,<sup>71</sup> and are also valid for analyzing metalloaromaticity. 72 For triangular systems, it is important to note that the MCI and  $I_{\rm ring}$  values are equivalent. In such cases, the MCI and  $I_{ring}$  values measure the degree of simultaneous electron sharing between different centers and can be used to estimate aromaticity.

To compare the aromaticity of different rings, MCI value needs to be normalized to the number of atoms (n),  $MCI^{1/n}$ , as MCI is known to be dependent on ring size. 73,74 The normalized MCI<sup>1/3</sup> value for benzene is 0.65 e, (obtained using CAM-B3LYP/6-311G(d,p) $^{75}$ ). For Al $_3$ , the normalized MCI value is larger, 0.85 e, while the inclusion of electron correlation reduces the MCI<sup>1/3</sup> value to 0.79. Therefore, it is clear that these triangles are aromatic. As we will be working with molecules of the same size, we will focus on the MCI indices, see Table 1. When analyzing them, we observe large values for both the singlet and triplets, whereas the MCI values of the quintets are comparatively lower but not negligible, i.e., MCI<sup>1/3</sup> are 0.49 and 0.43 for Al<sub>3</sub><sup>-</sup> and Tl<sub>3</sub><sup>-</sup> respectively.

To better understand the origin of aromaticity, we looked at the  $\pi$  and  $\sigma$ -aromaticities separately, (see MCI $_{\pi}$  in Table 1, and note that  $MCI_{\sigma_T} = MCI - MCI_{\pi}$ ). While the origin of the  $\pi$ -aromaticity is directly linked with the  $\Psi_{\pi}$  MOs set, the  $\sigma_T$ -aromaticity ( $\sigma$  total aromaticity) can arise from the other three different sets,  $\Psi_{\sigma}$ ,  $\Psi_{r}$ , and  $\Psi_{t}$ , shown in Fig. 1. We found that in the  ${}^{1}A'_{1}$  ground states,  $MCI_{\sigma_{T}}$  was slightly larger than  $MCI_{\pi}$ . In the  ${}^{3}B_{2}$  states, an electron was excited from the radial  $a'_1$  NO, to the tangential  $b_2$ , resulting in a reduction of  $MCI_{\sigma_{op}}$ with values ranging from 0.07 e for Tl<sub>3</sub><sup>-</sup> to 0.13 e for Al<sub>3</sub><sup>-</sup>. In the quintets, another electron is excited from the  $\pi$   $a_2''$  NO to the second degenerate tangential NO, leaving the a", a' and both e' MOs singly occupied. As a result, both  $MCI_{\pi}$  and  $MCI_{\sigma_{\pi}}$  were reduced (see Table 1).

Together with the MCI, DI can help us construct a vision of the electronic structure of the system. In Table 1, the total DI  $\delta(X_3^-)$  are shown. These numbers give us an estimation of the number of electron pairs delocalized in the system. According to these indexes, the delocalization is significant, very large in the singlets, and smaller for the triplets and quintets.

The  $\delta(X_3^-)$  indexes for the quintets are noteworthy, ranging from 2.46 for  $Al_3$  to 2.30 for the  $Tl_3$ . For the  $D_{3h}$  symmetry states, the properties of the three bonds are equal, so are the atom-pair DI, however for the  $C_{2v}$  symmetry triplets, we have two long and one short bonds with different atom-pair DI as it can be seen in Table 1.

In order to gain a deeper understanding of the origin of the DI, we have separated the contribution of each molecular orbital sets (described in Fig. 1) to the atom-pair DI. The resulting figures are collected in Table 2 (note that for the sake of brevity the two extreme cases are shown, Ga<sub>3</sub><sup>-</sup> and In<sub>3</sub> data is summarized in the ESI,† see Table S2). An examination of the <sup>1</sup>A<sub>1</sub>"-Al<sub>3</sub> DIs, describe that 1.5 electron-pairs (0.48  $\times$  3) are delocalized in the  $\Psi_{\sigma}$  set, alongside two delocalized electron pairs one in the  $\pi$ - and the second in the r-set. The main difference for the Tl<sub>3</sub> is the reduction of the delocalization of the  $\Psi_{\sigma}$  set. In the context of triplets, the delocalization of the  $\Psi_{\sigma}$  and  $\Psi_{\pi}$  sets is very similar to that of the singlet states, while the delocalization of the radial set reduces to 0.24 electron-pairs with a simultaneous increase in the delocalization of the  $\Psi_t$ -set. This behavior is what we could expect since an electron from the  $\Psi_{\rm r}$ -set is excited to one of the  $\Psi_{\rm t}$  sets. Finally, in the  ${}^5{\rm A}_2''$ states,  $\Psi_{\pi}$ -delocalization is also reduced and  $\Psi_{t}$  DI increases again as a consequence of the excitation of one of the  $\pi$ -electrons to the second  $\Psi_t$  tangential set.

The adaptive natural density partitioning analysis (AdNDP) method<sup>45</sup> has also been applied to our molecules. AdNDP localizes the valence electrons in 1-center 2-electron bonds (1c-2e), 2-center 2-electron bonds (2c-2e) and n-center 2-electron bonds (nc-2e). For the singlet states, AdNDP produces three possible bonding pictures, as shown in Fig. 2. The first one consists of three lone pairs (occupation numbers, ON = 1.78 |e|), and two 3c-2e bonds (ON = 1.99 |e|) of  $\sigma$  and  $\pi$ nature. An analogous picture is obtained instead by localizing the electronic density into 2c-2e bonds (ON = 1.99) along with the same two 3c-2e bonds (ON = 1.99 |e|). Lastly, the electronic density can be fully delocalized into 3c-2e bonds (ON = 1.99 |e|) (see Fig. 2C). These five 3c-2e AdNDP bonds and the  $a'_1$ , e', e'(of the  $\Psi_{\sigma}$  set), the  $a_2''$  (of the  $\Psi_{\pi}$  set) and  $a_1'$  (of the  $\Psi_{r}$  set) natural orbitals shown in Fig. 1 are similar in shape. The latter description is in agreement with the high delocalization found in these molecules. The co-existence of the two alter-

Table 2 Contribution of the different MO sets (see Fig. 1) to the atom-pair DIs for the Al<sub>3</sub><sup>-</sup> and Tl<sub>3</sub><sup>-</sup> different electronic states. The first values of the triplet correspond to the symmetric atom-pair corresponding to the two short bonds while the second corresponds the atom-pairs forming the longest bond

**PCCP** 

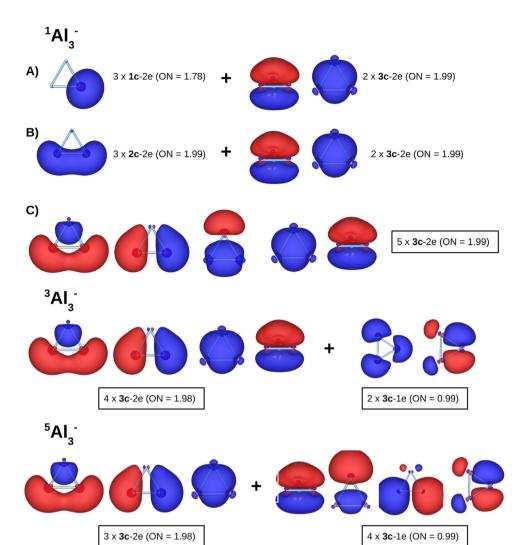

Fig. 2 AdNDP analysis of  $Al_3^{-1}A_1'$ ,  ${}^3B_2$  and  ${}^5A_5''$  states

native localization schemes (A and B in Fig. 2) and the fully delocalized scheme (C in Fig. 2) suggests that there is a resonance between these solutions, reflecting the delocalized nature of the electronic density in these molecules, a fact directly related to the aromaticity. For the triplet states, we can identify the 3c-2e bonds related with the  $\Psi_{\sigma}$  and  $\Psi_{\pi}$  sets, and the 3c-1e bonds related to  $\Psi_{\rm r}$  and  $\Psi_{\rm t}$  sets, while for the quintets, the  $\Psi_{\sigma}$  are related with the 3c-2e bonds and the four 3c–1e bonds are related with the  $\pi$ -, r-sets, and the last two with the tangential sets respectively (see Fig. 2).

Finally, the iso-chemical-shielding surfaces method<sup>46,47</sup> was also used to quantify the direction and scale of the anisotropy effect (see Fig. 3). This approach can characterize aromaticity and antiaromaticity. The shielding lobes (represented in blue) surrounded by donuts like deshielding loops (represented in green) in the planar plane, describe aromatic systems, while the opposite represents an antiaromatic system. Thus, according to the ICSS, the singlet and quintet states exhibit an aromatic character, while the triplet is antiaromatic.

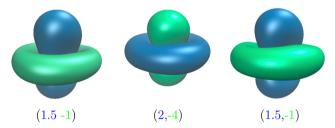

Fig. 3 ICSS plots for Al<sub>3</sub><sup>-</sup> singlet, triplet, and quintet respectively. Shielding surface is shown in blue and de-shielding surfaces in green. Isovalues for the isosurfaces are shown in parentheses. The same ICSS description is found for the rest of Ga<sub>3</sub><sup>-</sup>, In<sub>3</sub><sup>-</sup>, and Tl<sub>3</sub><sup>-</sup> triangles.

#### 4 Discussion

After conducting a thorough analysis of the aromaticity of these structures, we have been able to rationalize it using Mandado's rules<sup>76</sup> who established general rules for predicting the aromaticity based on the separate  $\alpha/\beta$  electron counting. Systems with  $(2n+1) \alpha$ - (or  $\beta$ -) electrons are expected to be aromatic, whereas

**PCCP** Paper

those containing  $2n \alpha$  (or  $\beta$ -) electrons are antiaromatic (n = 1) 0, 1, 2).

In Table 3 we have summarized the outcomes after applying Mandado's rules for  $\alpha$  and  $\beta$  electrons on each of the four independent MOs sets (see Fig. 1). Starting with the singlet, we have 3  $\alpha$  and  $\beta$  electrons in the  $\Psi_{\sigma}$  set, which follows Mandado's rule  $(2 \times 1 + 1)$  either for an  $\alpha$ - and  $\beta$ -aromatic system. The σ-aromaticity of this MO set is corroborated by the MCI, DI, and AdNDP analyses shown above. The  $\Psi_{\pi}$  set is doubly occupied, thus also meets Mandado's rule (2 × 0 + 1) for  $\alpha$  and  $\beta$  electrons, being this set the one that provides  $\pi$ -aromaticity. Similarly,  $\Psi_r$  provides additional  $\sigma$ -aromaticity in agreement with MCI, DI, and AdNDP results. Therefore the singlets present two  $\sigma$ - and a  $\pi$ -aromatic systems, overall being an aromatic molecule which is in agreement with ICSS description (see Fig. 3).

Moving to the  ${}^{3}B_{2}$  states, the description of the  $\Psi_{\sigma}$  and  $\Psi_{\pi}$ molecular sets is identical to that of the singlet described above. However the picture changes for  $\Psi_r$ , since now it is singly occupied with an  $\alpha$  electron, so is the  $\Psi_t$ . We can attribute  $\alpha$ -aromaticity to the  $\Psi_{\rm r}$ , (2  $\times$  0 + 1), but we should be careful when analyzing  $\Psi_t$ . While conducting an analytical assessment, it is plausible to inadvertently apply the  $(2 \times 0 + 1)$ rule and consider  $\Psi_t$  aromatic, however, is crucial to note that within the tangential set, due to the odd  $(D_{3h})$  symmetry MOs are ordered as two degenerate orbitals caped by a nondegenerate one,77 (see Fig. 4). One of these degenerate MOs contains a single electron, being the other degenerate tangential orbital empty. Therefore, a combination of Mandado's and Baird's rules is warranted, resulting in the (2n) rule for aromatic compounds and the (2n + 1) rule for antiaromatic compounds (observe the MO orbital arrangement for odd symmetry molecules shown in Fig. 4). According to Mandado's rule extension, the  $\Psi_t$  contribution is  $\alpha$ -antiaromatic (2  $\times$  0 + 1). Accordingly, the triplet presents what is known as conflicting aromaticity,<sup>78</sup> where  $\Psi_{\sigma}$  and  $\Psi_{r}$  present  $\sigma$ -aromatic contribution, the  $\Psi_{\pi}$ aromatic contributions while the  $\Psi_{\rm t}$  contribution is antiaromatic. The latter contribution could explain the deshielding cones of the <sup>3</sup>B<sub>2</sub> after applying a magnetic field (see Fig. 3). Atom-pair DIs have different values when comparing the two symmetric bonds with the third bond, in the case of Al<sub>3</sub>, the  $\delta_{i,i}$  corresponding to the long bond is slightly smaller than the values of the shorter bonds (1.00 vs. 0.92 a.u.), and this difference increases as increases the size of the atoms with values of 0.97 and 0.63 a.u. for Tl<sub>3</sub><sup>-</sup>. This DI partial alternation pattern can be associated with antiaromaticity.<sup>79</sup> AdNDP also

Fig. 4 Baird aromaticity representation for tangential MOs set. On the left-hand side, the arrangement corresponding to a  $D_{3h}$  odd symmetry system is shown, and the arrangement corresponding to even symmetry  $(D_{4h})$  is on the right. Notice that Bairds classical aromaticity rule can be straightforwardly applied to even symmetry systems (4n) while due to the MOs rearrangement in odd symmetry systems, the Baird rule will turn into the (2n) rule.

agrees with the antiaromaticity description for this state. Analyzing the AdNDP objects (or bonds), we can associate one of 3c-1e objects with the radial aromaticity, which meets Mandado's aromaticity rule, and a single 3c-1e object associated to the tangential aromaticity describing an antiaromatic system for this state.

Finally, focusing on the quintets, we have the same description for the  $\Psi_{\sigma}$  as in the cases above, providing  $\sigma$ -aromaticity character to the molecule. The rest of the electrons are  $\alpha$ electrons distributed as follows: one in  $\Psi_{\pi}$  and  $\Psi_{r}$  sets, which according to Mandado's rules, provide  $\pi$ -(the former) and  $\sigma$ -(the later) aromaticity to the system, and the last two, are in the  $\Psi_t$  set, one electron in each of the degenerate orbitals, which agrees with Baird's and Mandado's rules combination  $(2 \times 1)$  for aromaticity. This description is in agreement with MCI (note that, though, MCI values are much smaller than those of the singlet and triplet). DI also agrees with this description, giving reasonable values for the  $\pi$ -, radial and tangential sets, but smaller than the singlet and triplet DIs. Finally, AdNDP reports four objects formed by one electron and three centers, where two of these centers are associated with the tangential set, thus are α-Baird aromatic, and the other two sets are describing  $\alpha$   $\pi$ - and  $\alpha$   $\sigma$ -aromaticity.

Comparing the aromaticity of the different compounds, we can say that it reduces when increasing the size of the atom, but still, we can state that the <sup>5</sup>A<sub>2</sub>"-Tl<sub>3</sub> molecule exhibits some degree of aromaticity, albeit significantly lower compared to the <sup>1</sup>A<sub>1</sub>-Tl<sub>3</sub><sup>-</sup>. However, the high-spin <sup>5</sup>A<sub>2</sub>" state is the lowest in energy for Tl<sub>3</sub><sup>-</sup>, and its photo-electron spectra matches the experimental spectra available for Tl<sub>3</sub><sup>-</sup>. Surprisingly, the stability of this state contradicts the conventional belief that higher

**Table 3** The number of  $(\alpha/\beta)$  electrons of each set is shown, and its aromaticity (A)/antiaromaticity (AA) outcomes after applying Mandado's rules to each of the four independent MOs sets.  $\sigma/\pi$  stand for the corresponding aromaticity type

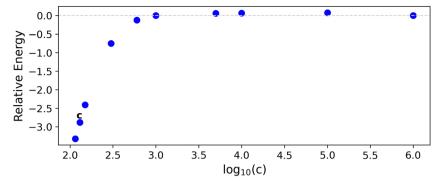

Fig. 5 Relative Energy change of  $\operatorname{Tl}_3^-(E({}^5A_1'')-E({}^1A_1')$ , in kcal  $\operatorname{mol}^{-1})$  with respect to logarithm of the speed of the light (in a.u.) used in the relativistic calculations. Note that the point corresponding to the real speed of the light ( $log_{10}(137.0359895)$ ) is indicated with a c label

aromaticity leads to increased stability, as the singlet state is considerably more aromatic than the quintet. Despite different indicators also suggest that the quintet state is aromatic, its aromaticity remains inferior to that of the singlet state. The stability of the quintet could be attributed to the relativistic effects present in the  $Tl_3$  molecule, which equalize the  $a_2''$ ,  $a_1'$ , and both degenerate e' orbitals in energies. As a consequence of this stabilization, are then filled up according to Hund's rule, with one electron each, being the relativistic effects more important than the stability provided by the aromaticity in the singlet state. Previous studies by Pino-Rios et al.80 have also reported a loss of aromaticity due to relativistic effects, although they attributed it to spin-orbit coupling. However, the spin-orbit coupling for the Tl<sub>3</sub> - triangles under investigation was found to be relatively small (less than 5 cm<sup>-1</sup>).

To account for the relativistic effects, the  $Tl_3^{-1}A'_1$  and  ${}^5A''_5$ states where recalculated at the MCSCF (10,12) level of theory incorporating dynamic correlation through CASPT2, and employing the zeroth-order regular approximated (ZORA)81 method with the SARC-ZORA-TZVPP82 basis set as implemented in ORCA.83 The geometries obtained with ZORA closely resemble the previous ones, with bond lengths of 3.147 and 3.282 Å for the singlet and the quintet respectively, the singlet being 2.91 kcal mol<sup>-1</sup> higher in energy.

We conducted additional calculations by modulating the relativistic effects, altering the value of the speed of the light used in the ZORA Hamiltonian (note that increasing the speed of the light value in the Hamiltonian reduces the relativistic effects). These effects are clearly depicted in Fig. 5. As the speed of light is increased to larger values, the energy difference between the two states diminishes. When the speed of light is increased sufficiently, to the point where relativistic effects are neglected, both states become nearly energetically degenerated, indicating that relativistic effects favor the quintet with respect to the singlet.

#### Conclusions

High-level ab-initio quantum mechanics calculations have been performed to characterize the lowest-lying states of the  $X_3$  triangles, X = Al, Ga, In, and Tl.

We have assign to  ${}^{5}A_{2}''$ -Tl<sub>3</sub><sup>-</sup> and to  ${}^{1}A_{1}'$ -In<sub>3</sub><sup>-</sup> the experimental signals detected by Gausa et al. back in 1990, and we attribute the stability of the <sup>5</sup>A<sub>2</sub>"-Tl<sub>3</sub><sup>-</sup> to relativistic effects.

Analyzing the electronic structures of these triangular structures, and applying Mandado's aromaticity/antiaromaticity rules, we have been able to rationalize the aromaticity of these molecules, which are in agreement with the different electron density methods employed (MCI, DI, and AdNDP) and the ICSS, which represents the response of the molecule to a external magnetic field of the molecule. The separate analysis of the  $\alpha$ and β-electrons made possible to explain the antiaromatic character (the deshielding cone in the ICSS) of the <sup>3</sup>B<sub>2</sub> as a consequence of the single  $\alpha$  electron present in the  $\Psi_t$ orbital set.

Summarizing, the  ${}^{1}A'_{1}$  electronic states present multiple-fold aromaticity, specifically 3-fold aromaticity, being the origin the  $\Psi_{\sigma}$  and  $\Psi_{r}$  sets, providing  $\sigma$ -aromaticity, and the  $\Psi_{\pi}$  which provides  $\pi$ -aromaticity to all the studied singlet states. The triplets are  $\pi$ -aromatic but they do also present certain  $\sigma$ -aromaticity, originated from the inner  $\Psi_{\sigma}$  and the  $\alpha$  electron present in the  $\Psi_r$ . However, the antiaromatic character of the  $\alpha$ electron in the  $\Psi_t$  causes a magnetic shielding/deshielding response associated with an antiaromatic system, as reported by ICSS. The quintets also present some aromatic character, which despite being smaller than that of the singlet and triplet, it is not negligible. According to Mandado's rules, the  $\Psi_{\sigma}$  set is  $\alpha/\beta$   $\sigma$ -aromatic, the  $\Psi_{\pi}$  set  $\alpha$   $\pi$ -aromatic, and the  $\Psi_{t}$  set  $\alpha$   $\sigma$ -Baird aromatic, in agreement with the diamagnetic response of the quintet.
