Chiroptical activity of benzannulated N-heterocyclic carbene rhenium(I) tricarbonyl halide complexes: towards efficient circularly polarized luminescence emitters

The computed and experimental (chiro-)optical properties of a series of eight enantiopure phosphorescent N-heterocyclic carbene rhenium(I) tricarbonyl complexes are compared in terms of ECD and CPL activities. The study deciphers the effect exerted by the nature of the low-lying electronic excited states onto the chiro-optical properties, paving the way to the design of enantiomerically pure circularly polarized luminescent CPL emitters.
