Transition metal complexes of the (2,2,2-trifluoroethyl) phosphinate NOTA analogue as potential contrast agents for  $^{19}\text{F}$  magnetic resonance imaging

Cite this: *Dalton Trans.*, 2024, **53**, 9267

# Transition metal complexes of the (2,2,2-trifluoroethyl)phosphinate NOTA analogue as potential contrast agents for $^{19}\text{F}$ magnetic resonance imaging†

Filip Koucký,<sup>a</sup> Tereza Dobrovolná,<sup>a</sup> Jan Kotek,<sup>a</sup> Ivana Císařová,<sup>a</sup> Jana Havlíčková,<sup>a</sup> Alan Liška,<sup>b</sup> Vojtěch Kubiček<sup>a</sup> and Petr Hermann<sup>a</sup>

A new hexadentate 1,4,7-triazacyclononane-based ligand bearing three coordinating methylene-(2,2,2-trifluoroethyl)phosphinate pendant arms was synthesized and its coordination behaviour towards selected divalent ( $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Mn}^{2+}$ ,  $\text{Fe}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Zn}^{2+}$ ) and trivalent ( $\text{Cr}^{3+}$ ,  $\text{Fe}^{3+}$ ,  $\text{Co}^{3+}$ ) transition metal ions was studied. The ligand forms stable complexes with late divalent transition metal ions (from  $\text{Co}^{2+}$  to  $\text{Zn}^{2+}$ ) and the complexes of these metal ions are formed above  $\text{pH} \sim 3$ . A number of complexes with divalent metal ions were structurally characterized by means of single-crystal X-ray diffraction. The complex of the larger  $\text{Mn}^{2+}$  ion adopts a twisted trigonally antiprismatic geometry with a larger coordination cavity and smaller torsion of the pendant arms, whereas the smaller ions  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$  and  $\text{Zn}^{2+}$  form octahedral species with a smaller cavity and larger pendant arm torsion. In the case of the  $\text{Co}^{2+}$  complexes, both coordination arrangements were observed. The complexes with paramagnetic metal ions were studied from the point of view of potential utilization in  $^{19}\text{F}$  magnetic resonance imaging. A significant shortening of the  $^{19}\text{F}$  NMR longitudinal relaxation times was observed: a sub-millisecond range for complexes of  $\text{Cr}^{3+}$ ,  $\text{Mn}^{2+}$  and  $\text{Fe}^{3+}$  with symmetric electronic states ( $t_{2g}^3$  and  $\text{HS-}d^5$ ), the millisecond range for the  $\text{Ni}^{2+}$  and  $\text{Cu}^{2+}$  complexes and tens of milliseconds for the  $\text{Co}^{2+}$  complex. Such short relaxation times are consistent with a short distance between the paramagnetic metal ion and the fluorine atoms ( $\sim 5.5$ – $6.5$  Å). Among the redox-active complexes ( $\text{Mn}^{3+}/\text{Mn}^{2+}$ ,  $\text{Fe}^{3+}/\text{Fe}^{2+}$ ,  $\text{Co}^{3+}/\text{Co}^{2+}$ ,  $\text{Cu}^{2+}/\text{Cu}^{+}$ ), the cobalt complexes show sufficient stability and a paramagnetic–diamagnetic changeover with the redox potential lying in a physiologically relevant range. Thus, the  $\text{Co}^{3+}/\text{Co}^{2+}$  complex pair can be potentially used as a smart redox-responsive contrast agent for  $^{19}\text{F}$  MRI.

## Introduction

Magnetic Resonance Imaging (MRI) is one of the most powerful imaging methods in current medicine. Compared to the classical radiological methods utilizing ionizing radiation such as Computed Tomography (CT), Single-Photon Emission

Computed Tomography (SPECT) or Positron Emission Tomography (PET), MRI utilizes the nuclear magnetic resonance effect and uses non-ionizing radiation for detection which brings a strong benefit to the patients. Classical MRI utilizes the detection of the NMR effect of water  $^1\text{H}$  nuclei and distinguishes the different tissues according to the water content and/or signal relaxation times (longitudinal,  $T_1$ , and transversal,  $T_2$ ). The image contrast can be further improved by the application of contrast agents (CAs) which influence the water proton relaxation times, and a suitable experimental setup selectively increases or decreases the water  $^1\text{H}$  signal according to the CA distribution in the tissue.<sup>1</sup> Other MRI techniques have been developed, including the detection of  $^1\text{H}$  signals of compounds other than water (*e.g.* fat) or utilization of responsive (“smart”) contrast agents which change their properties according to the surrounding conditions.<sup>2</sup> In addition, other NMR active nuclei such as  $^{13}\text{C}$ ,  $^{19}\text{F}$  or  $^{31}\text{P}$  can also be detected by MRI.<sup>3</sup> Among them, fluorine is of special

interest, as it is a monoisotopic element with a high gyromagnetic ratio which provides a very high sensitivity towards the NMR effect. The gyromagnetic ratio of  $^{19}\text{F}$  is very close to that of  $^1\text{H}$  which enables the detection of the  $^{19}\text{F}$  NMR signal with the use of standard MRI scanners with only small hardware and software modifications. Furthermore, fluorine has almost no abundance in living organisms and, thus, it has no natural background in the imaging experiments. This fact predisposes the  $^{19}\text{F}$  nuclei for “hot-spot” imaging where only the externally supplied xenobiotic contrast agent molecules provide the  $^{19}\text{F}$  MRI signal.<sup>4</sup> As both  $^1\text{H}$  and  $^{19}\text{F}$  MRI experiments can be performed on the same hardware, the need to overlay  $^{19}\text{F}$  “hot-spots” with the anatomical image can be elegantly solved by  $^1\text{H} + ^{19}\text{F}$  tandem MRI.<sup>5</sup> Such an imaging method could be especially useful for example for following the fate of labelled cells after transplantation.<sup>6</sup>

The compounds first tested as  $^{19}\text{F}$  NMR contrast agents were usually highly fluorinated hydrocarbons and their derivatives (for simplicity called perfluorocarbons, PFCs). The design of fluorinated contrast agents takes advantage of the generally high stability of the C–F bond towards hydrolysis which makes these compounds inert and non-biodegradable.<sup>7</sup> Highly fluorinated organic compounds therefore usually exhibit a low acute toxicity, and some of the PFCs have been already studied for a long time as potential blood substitutes due to the high solubility of molecular oxygen<sup>8–11</sup> or as materials in vitreo-retinal surgery due to their optical properties.<sup>12,13</sup> Although some adverse health effects have been reported in the latter application,<sup>14</sup> they have been attributed mainly to the presence of trace toxic impurities like non-fully substituted hydrocarbons and other derivatives.<sup>15,16</sup> However, although PFCs show high stability, it was recently found that they cause some environmental risks.<sup>17</sup>

The compounds originally used for  $^{19}\text{F}$  MRI are not water-soluble and have been used in the form of nano- or micro-emulsions which complicates some applications (e.g. cellular labelling). Further complication arises from a generally long  $T_1$  relaxation time of the  $^{19}\text{F}$  nucleus in the PFC (order of seconds). Therefore, a signal is acquired for several seconds, a long delay between excitation pulses is needed and it prolongs the whole experiment. To solve this problem, complexes of fluorine-containing ligands with some paramagnetic metal ions were introduced, as the presence of a paramagnetic metal ion strongly influences the NMR relaxation times of nuclei in the vicinity.<sup>18</sup> The concentration of the contrast agents must be relatively high (on a millimolar scale) to achieve a reasonable signal-to-noise ratio. Therefore, the complexes must exhibit exceptional kinetic inertness as the free metal ions are frequently toxic and, in addition, the contrast agent loses convenient relaxation properties after the dissociation of the complexes. Therefore, the ligands are often based on a macrocyclic scaffold, mostly on 1,4,7-triazacyclononane (tacn), 1,4,7,10-tetraazacyclododecane (cyclen) or 1,4,8,11-tetraazacyclotetradecane (cyclam), Fig. 1, with suitably chosen coordinating pendant arms or substituents which contain fluorine atoms. The first explored groups were derivatives and analogues of cyclen-based  $\text{H}_4\text{dota}$  (Fig. 1),<sup>19–31</sup> the octadentate ligand family

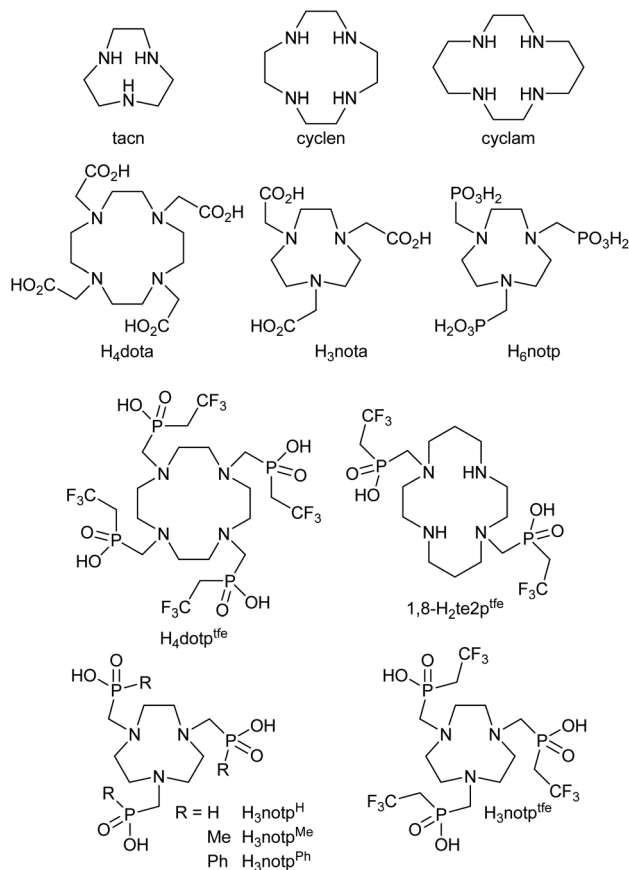

Fig. 1 Ligands mentioned in the text.

very suitable for complexation of the lanthanide(III) ions. The  $\text{Ln}^{3+}$  complexes of such ligands are generally kinetically inert (the  $\text{Gd}^{3+}$  complexes are used as ordinary  $^1\text{H}$  MRI CAs),<sup>32</sup> and a range of magnetic properties of individual  $\text{Ln}^{3+}$  ions brings a possibility of tuning the properties of the final CAs.<sup>21,25,31</sup> More recently, complexes of transition metal ions have also been found to effectively shorten the NMR relaxation times of close  $^{19}\text{F}$  nuclei.<sup>33</sup> For complexation of transition metal ions,  $\text{H}_4\text{dota}$  derivatives have also been used,<sup>28,34,35</sup> but hexadentate derivatives of tacn and cyclam are generally more suitable for this purpose.<sup>36</sup> Therefore, several tacn derivatives with three coordinating pendant arms containing fluorine were prepared and studied.<sup>37–40</sup> Similarly, cyclam-based ligands with two coordinating groups have also been studied.<sup>41–47</sup>

In our previous contributions, we showed that (2,2,2-trifluoroethyl)phosphinic acid is a suitable synthon for the introduction of the fluorine atoms into a ligand molecule. We used this coordinating pendant arm in the synthesis of the cyclen-based ligand  $\text{H}_4\text{dotp}^{\text{ffe}}$  (Fig. 1) which contains twelve fluorine atoms and we studied its  $\text{Ln}^{3+}$  complexes.<sup>31</sup> Recently, the same pendant arm has been utilized in the cyclam-based ligand  $1,8\text{-H}_2\text{te}2\text{p}^{\text{ffe}}$  (Fig. 1) containing six fluorine atoms and a study of its transition metal complexes was reported.<sup>47</sup> The results showed that such a concept is viable and brought promising data especially for the  $\text{Co}^{2+}$  complex.<sup>47</sup>

To extend our work in this field, we designed a new tacn-based ligand containing three [methylene-(2,2,2-trifluoroethyl) phosphinic acid] pendant arms,  $\text{H}_3\text{notp}^{\text{te}}$  (Fig. 1). It increases the number of fluorine atoms in one small molecule to nine. It would potentially increase the visibility of the contrast agents during the imaging experiment. In this manuscript, we report on the synthesis of the designed ligand and the results of its coordination study with selected first-row transition metal ions.

## Experimental

### General

Commercial chemicals (Fluka, Aldrich, CheMatech, Lachema, Fluorochem) were used as obtained. Anhydrous solvents were obtained by established procedures.<sup>48</sup> 2,2,2-Trifluoroethyl-tosylate<sup>49</sup> and 2,2,2-trifluoroethylbromide<sup>50</sup> were prepared according to published procedures with slight modifications. (2,2,2-Trifluoroethyl)phosphinic acid was prepared analogously as reported earlier<sup>47</sup> but 2,2,2-trifluoroethylbromide was used instead of iodide and the workup was modified. Analytical HPLC-MS experiments were carried out on a Waters ACQUITY QDa system (detection: MS – electrospray ionization under atmospheric pressure,  $m/z$  100–1250; UV-Vis –  $\lambda$  210–800 nm, diode array) equipped with an RP column (Cortecs C18 2.7  $\mu\text{m}$ , 4.6  $\times$  50 mm) using a mixture of water with 0.1% trifluoroacetic acid (TFA) and MeCN with 0.1% TFA; for details on the chromatographic method, see Fig. S1.† Mass spectra were obtained on a Waters ACQUITY QDa with a direct loading using  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{O}$  with 0.1% TFA or MeOH for the sample dilution. Data were processed by Empower 3 software. Flash chromatography was performed on an ECOM ECS28P0X (UV-Vis diode-array detector,  $\lambda$  200–800 nm). Thin-layer chromatography (TLC) was performed on silica-coated aluminium sheets Silica gel 60 F254 (Merck). Spots were visualized using UV light (254 and 366 nm), dipping in 5% aq. solution of  $\text{CuSO}_4$  or in aq. solution containing 1%  $\text{KMnO}_4$  and 2%  $\text{Na}_2\text{CO}_3$ . UV-Vis spectra were recorded on spectrometer Specord 50 Plus (Analytic Jena) in a quartz-glass cell with an optical path of 1 cm. NMR spectra were recorded on a Varian VNMR300 (frequencies 299.9 MHz for  $^1\text{H}$ , 282.2 MHz for  $^{19}\text{F}$  and 121.4 MHz for  $^{31}\text{P}$ ), Varian Inova 400 MHz (frequencies 400.0 MHz for  $^1\text{H}$ , 100.6 MHz for  $^{13}\text{C}$ , 376.3 MHz for  $^{19}\text{F}$  and 161.9 MHz for  $^{31}\text{P}$ ) or Bruker Avance III 600 MHz (frequencies 600.2 MHz for  $^1\text{H}$ , 150.9 MHz for  $^{13}\text{C}$  and 564.7 MHz for  $^{19}\text{F}$ ). The spectra were acquired at 25 °C unless stated otherwise. Internal references for  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were *t*-BuOH for  $\text{D}_2\text{O}$  solutions and  $\text{CHD}_2\text{OD}$  residual peak for MeOH- $d_4$  solutions. Aq.  $\text{H}_3\text{PO}_4$  (3%) was used as the external reference for  $^{31}\text{P}$  NMR (0.5 ppm) and *ca.* 1% triflic acid for  $^{19}\text{F}$  NMR (–79.0 ppm). These secondary references were referenced to 85%  $\text{H}_3\text{PO}_4$  (0.0 ppm) and to Freon-11 (0.0 ppm), respectively. Chemical shifts are given in ppm and coupling constants in Hz. Multiplicities of the signals are expressed as follows: s (singlet), d (doublet), t (triplet), q (quartet), and m (multiplet).

Chemical shifts of paramagnetic compounds were corrected for a bulk magnetic susceptibility effect as described previously (difference of the  $^{19}\text{F}$  signals of 2,2,2-trifluoroethanol between the paramagnetic sample and the insert, Table S1†);<sup>47</sup> the corrected values are presented throughout the text. The  $T_1$  relaxation times of the nucleus were measured using the Inversion Recovery sequence. The  $^{19}\text{F}$   $T_2$  relaxation times of diamagnetic compounds were measured from the CPMG sequence on a Varian Inova 400 MHz and Bruker III 600 MHz; the measurement is not accessible on VNMR300 as the probe used does not provide accurate 180° pulses for the  $^{19}\text{F}$  nuclei. For all paramagnetic complexes,  $T_2^*$  relaxation times were calculated from half-widths of their NMR signals.

### Ligand synthesis

**2,2,2-Trifluoroethyl-tosylate.** 2,2,2-Trifluoroethanol (30.0 g, 300 mmol, 1.0 equiv.) was poured into a 1000 ml round-bottomed flask and was diluted with dichloromethane (DCM, 300 ml). Triethylamine (84 ml, 600 mmol, 2.0 equiv.) was added and the mixture was cooled in a bath with a water-ice mixture. To this mixture, a solution of tosylchloride (54.3 g, 285 mmol, 0.95 equiv.) in DCM (150 ml) was added dropwise. After the addition was completed, the cooling bath was removed and the reaction mixture was allowed to warm up to room temperature and was stirred for 18 h. Thereafter, aq. HCl (6 M, 150 ml) was added and the mixture was transferred into a separation funnel. The organic layer was separated, washed with brine (3  $\times$  200 ml) and dried over anhydrous  $\text{MgSO}_4$ . Volatiles were evaporated on a vacuum rotary evaporator. The pale orange oil remaining was poured onto an evaporating dish. The white solid product crystallized in the fridge overnight. Yield 68.5 g (95%).

Elem. anal.: found (calc. for  $\text{C}_9\text{H}_9\text{F}_3\text{O}_3\text{S}$ ,  $M_r$  254.22) C: 42.44 (42.52), H: 3.43 (3.57), F: 21.27 (22.42), S: 12.10 (12.61).

NMR ( $\text{CDCl}_3$ ):  $^1\text{H}$ : 2.47 (s, 3H,  $\text{CH}_3$ ); 4.34 (q, 2H,  $^3J_{\text{HF}}$  8.0,  $\text{CH}_2$ ); 7.38 (d, 2H,  $^3J_{\text{HH}}$  8.2, *arom.*); 7.81 (d, 2H,  $^3J_{\text{HH}}$  8.2, *arom.*).  $^{13}\text{C}\{^1\text{H}\}$ : 21.8 ( $\text{CH}_3$ ); 64.7 (q,  $^2J_{\text{CF}}$  38.1,  $\text{CH}_2$ ); 122.7 (q,  $^1J_{\text{CF}}$  277,  $\text{CF}_3$ ); 128.2, 130.3, 132.0, 146.1 (4  $\times$  *arom.*).  $^{19}\text{F}$ : –74.2 (t,  $^3J_{\text{FH}}$  8.0,  $\text{CF}_3$ ).

Recrystallization from boiling 96% aq. EtOH afforded single-crystals suitable for determination of the crystal structure by X-ray diffraction. The crystal structure is the same as that already reported,<sup>51</sup> but with significantly better parameters of refinement (see the ESI, Table S4 and Fig. S34†).

**2,2,2-Trifluoroethylbromide.** The non-trivial apparatus is shown in Fig. S2.† 2,2,2-Trifluoroethyl-tosylate (105 g, 413 mmol), diethyleneglycol (250 ml), KBr (75.0 g, 630 mmol, 1.5 equiv.) and a few ceramic boiling chips were added into a 1000 ml three-necked round-bottomed flask in a heating mantle. The flask necks were equipped with a stopcock connected to a  $\text{N}_2$  (g) source, a Dimroth condenser and a stopper. The Dimroth condenser was connected to an adapter with a thermometer and a low-temperature side condenser which was filled with ethanol. The temperature in the low-temperature condenser was maintained around –70 °C by periodic addition of liquid  $\text{N}_2$ . A 100 ml round-bottomed receiving flask was con-

nected to the low-temperature condenser and cooled in a Dewar vessel which was filled with ethanol and N<sub>2</sub> (l). Water for the Dimroth condenser was pre-heated to 35 °C (the boiling point of the product is approx. 26 °C). The reaction mixture was heated to reflux diethyleneglycol (245 °C) and 2,2,2-trifluoroethyl-tosylate and KBr fully dissolved at the high temperature. The product was distilled as a colourless high-density liquid. The yield was 65.9 g (98%).

NMR (20% v : v solution in CH<sub>2</sub>Cl<sub>2</sub>, 20 °C): <sup>1</sup>H: 3.72 (q, 2H, <sup>3</sup>J<sub>HF</sub> 8.9, CH<sub>2</sub>). <sup>13</sup>C{<sup>1</sup>H}: 26.4 (q, <sup>2</sup>J<sub>CF</sub> 37.8, CH<sub>2</sub>); 123.7 (q, <sup>1</sup>J<sub>CF</sub> 274, CF<sub>3</sub>). <sup>19</sup>F: -69.6 (t, <sup>3</sup>J<sub>FH</sub> 8.9, CF<sub>3</sub>).

#### (2,2,2-Trifluoroethyl)phosphinic acid and ammonium salt.

Under a stream of argon, crystalline hypophosphorous acid (5.00 g, 75.8 mmol) in a three-necked 250 ml flask was dissolved in anhydrous DCM (50 ml). The flask was immersed in a water-ice cooling bath and anhydrous *N,N*-diisopropyl-ethylamine (DIPEA, 29.4 g, 227 mmol, 3.0 equiv.) was added. Afterwards, trimethylsilyl chloride (TMS-Cl, 24.7 g, 227 mmol, 3.0 equiv.) was added dropwise; the rate of addition was kept slow to prevent a white haze from flowing away from the apparatus. After addition of the whole amount of TMS-Cl, the reaction mixture was stirred at room temperature for 3 h. Formation of bis(trimethylsilyloxy)phosphine was confirmed by <sup>31</sup>P NMR (141 ppm, d, <sup>1</sup>J<sub>PH</sub> 177).

Then, 2,2,2-trifluoroethylbromide (13.6 g, 83.5 mmol, 1.1 equiv.) dissolved in anhydrous DCM (20 ml) was added dropwise to the reaction mixture; the rate of the addition was slow enough to prevent haze formation. The mixture was stirred at room temperature overnight. Then, the reaction mixture (0.1 ml) was hydrolysed in 96% EtOH (1 ml) and <sup>31</sup>P NMR of the hydrolysed sample revealed *ca.* 72% conversion; the main impurity was H<sub>3</sub>PO<sub>3</sub>. The whole reaction mixture was hydrolysed by dropwise addition of 96% EtOH (60 ml). The hydrolysed mixture was evaporated on a rotary evaporator at the bath temperature of 50 °C. The residue was dissolved in water (30 ml) and the solution was poured onto a column of a strong cation exchange resin (Dowex 50, H<sup>+</sup>-cycle, 400 ml of aq. suspension) and a crude product was eluted off with water. During this procedure, only a part of DIPEA was kept on the column and some DIPEA was still present in the product (<sup>1</sup>H NMR). Therefore, chromatography on the same cation exchange column (re-converted to the H<sup>+</sup>-cycle) was repeated three more times (until the signals of DIPEA disappeared). The aqueous solution of the purified product was concentrated on a rotary evaporator at a maximum temperature of 40 °C in the bath.

The crude product free from DIPEA was purified on a silica column (100 g of dry SiO<sub>2</sub>) using conc. aq. NH<sub>3</sub>:EtOH at 1 : 25 as an eluent. Fractions containing the pure product were combined and evaporated in a vacuum affording ammonium (2,2,2-trifluoroethyl)phosphinate as a white solid. Yield 7.1 g (57%). Spectroscopic characteristics were identical to those reported previously.<sup>47</sup> The single crystals of the product were prepared by the slow evaporation of the aqueous solution to near dryness. Besides the simple ammonium salt, the single crystals of 1-adamantylammonium salt were prepared analo-

gously by evaporation of the aqueous solution of (2,2,2-trifluoroethyl)phosphinic acid obtained from the ammonium salt by elution through a strong cation exchanger (Dowex 50, H<sup>+</sup>-form, elution with water) neutralized with 1-adamantylamine. For data of these crystal structures, see the ESI (Table S4 and Fig. S35, S36†).

**1,4,7-Tris[[2,2,2-trifluoroethyl(hydroxy)phosphoryl]methyl]-1,4,7-triazacyclononane, H<sub>3</sub>notp<sup>tfc</sup> (H<sub>3</sub>L).** The ammonium salt of (2,2,2-trifluoroethyl)phosphinic acid (2.25 g, 13.6 mmol, 3.4 equiv.) was dissolved in distilled water (15 ml). The solution was loaded onto a column of a strong cation exchanger (Dowex 50, H<sup>+</sup>-form, 100 ml) and the free acid was eluted with water. The acid fraction was evaporated *in vacuo*. The absence of ammonium cations was confirmed by Nessler's reagent.

The oily residue was diluted in aq. TFA (50% v/v, 50 ml) and tacn (0.52 g, 4.0 mmol, 1.0 equiv.) was added. After its dissolution, paraformaldehyde (0.48 g, 16 mmol, 4.0 equiv.) was added in one portion. The flask was tightly closed and the suspension was stirred at 40 °C for 1 d. Then, an additional amount of paraformaldehyde was added (0.12 g, 4 mmol, 1 equiv.) and the reaction mixture was stirred at 40 °C for the next 1 d. After cooling, volatiles were removed in vacuum affording a brownish oil. It was diluted with water (10 ml) and loaded onto a column of a strong cation exchanger (Dowex 50, H<sup>+</sup>-form, 400 ml). Elution with water afforded the required product in a mixture with simple acids [starting with (2,2,2-trifluoroethyl)phosphinic acid, hydroxymethyl-(2,2,2-trifluoroethyl)phosphinic acid, (2,2,2-trifluoroethyl)phosphonic acid and traces of TFA]; the doubly substituted macrocycle derivatives remained on the column. The acid fraction was evaporated on a vacuum rotary evaporator. The crude oily product was diluted with water (10 ml) and purified in two portions by flash chromatography using a C18-AQ stationary phase (PuriFlash, 120 g). A gradient of MeCN in H<sub>2</sub>O was used (both solvents with 0.1% of TFA) with a flow of 50 ml min<sup>-1</sup>: 0.0 min 0% MeCN, 3.0 min 0% MeCN, 12.0 min 20% MeCN, 15.0 min 20% MeCN, 15.5 min 100% MeCN, and 18.5 min 100% MeCN. The product retention time was 9.8 min. The pure product-containing fractions were evaporated to dryness and the product was isolated as a non-stoichiometric trifluoroacetate (*ca.* 0.3 molar equiv. according to <sup>19</sup>F NMR). The yield was 1.26 g (*ca.* 49%) of colourless glassy oil.

NMR (H<sub>3</sub>notp<sup>tfc</sup>·0.3TFA, D<sub>2</sub>O, pD 0.5): <sup>1</sup>H: 2.88 (dq, 6H, <sup>2</sup>J<sub>HP</sub> 14.6, <sup>3</sup>J<sub>HF</sub> 11.8, PCH<sub>2</sub>CF<sub>3</sub>); 3.44 (d, 6H, <sup>2</sup>J<sub>HP</sub> 6.4, NCH<sub>2</sub>P); 3.61 (s, 12H, NCH<sub>2</sub>CH<sub>2</sub>N). <sup>13</sup>C{<sup>1</sup>H}: 36.5 (dq, <sup>1</sup>J<sub>CP</sub> 86.4, <sup>2</sup>J<sub>CF</sub> 28.4, PCH<sub>2</sub>CF<sub>3</sub>); 52.4 (s, NCH<sub>2</sub>CH<sub>2</sub>N); 56.3 (d, <sup>1</sup>J<sub>CP</sub> 99.0, NCH<sub>2</sub>P); 125.4 (qd, <sup>1</sup>J<sub>CF</sub> 275, <sup>2</sup>J<sub>CP</sub> 3.1, CF<sub>3</sub>). <sup>19</sup>F: -57.5 (td, <sup>3</sup>J<sub>FH</sub> 11.75, <sup>3</sup>J<sub>FP</sub> 8.7), -75.8 (s, TFA). <sup>31</sup>P: 23.6 (broad s). MS-ESI: (+): 610.4 ([M + H]<sup>+</sup>, calc. 610.1); (-): 608.3 ([M - H]<sup>-</sup>, calc. 608.1), 722.3 ([M + TFA - H]<sup>-</sup>, calc. 722.1). TLC: iPrOH : conc. aq. NH<sub>3</sub>:water 10 : 3 : 3; R<sub>f</sub> 0.85 (5% aq. CuSO<sub>4</sub>, blue spot). Purity was checked by HPLC (Fig. S1 and S3†) and <sup>1</sup>H, <sup>13</sup>C, <sup>19</sup>F and <sup>31</sup>P NMR spectroscopy (Fig. S4–S7†).

The ligand H<sub>3</sub>notp<sup>tfc</sup> for some experiments was further purified (removal of any remaining TFA) by chromatography on the strong cationic exchanger (Dowex 50, H<sup>+</sup>-form) with water

as an eluent; TFA is eluted off slightly earlier than  $\text{H}_3\text{notp}^{\text{tfe}}$  which is thus enriched in the later fractions. The fractions were analysed by  $^{19}\text{F}$  NMR spectroscopy and combined according to their purity. After repeated procedures, some amount of pure  $\text{H}_3\text{notp}^{\text{tfe}}$  was isolated as a colourless thick oil containing only some small amount of water as an impurity.

### Preparation of solutions of the complexes for NMR studies

The ligand stock solution was prepared by dissolution of  $\text{H}_3\text{notp}^{\text{tfe}}$  (600 mg, TFA-free) in water into a 25 ml volumetric flask. The exact ligand concentration (38.3 mM) was determined by  $^{19}\text{F}$  qNMR using standardized aq. solution of TFA similarly as described previously.<sup>47</sup>

For determination of magnetic moments, the samples were prepared by mixing exactly the measured volume (200–300  $\mu\text{l}$ ) of the aq. ligand stock solution, the appropriate amount of the aq. stock solution of the metal ion salts ( $\text{MnCl}_2$ ,  $(\text{NH}_4)_2\text{Fe}(\text{SO}_4)_2$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$ ,  $\text{CuCl}_2$ ; 0.95 equiv., concentration determined by chelatometry), appropriate amount of 1.50 M aq. NaOH (2.90 equiv.) and exactly measured volume (200–300  $\mu\text{l}$ ) of aq. HEPES buffer (0.1 M) with pH 7.4. The solutions of the  $\text{Mn}^{2+}$ ,  $\text{Fe}^{2+}$  and  $\text{Cu}^{2+}$  complexes were measured immediately (a fast complex formation) and the solutions of the  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  complexes were equilibrated at 50 °C in a tightly closed vial overnight. To prepare the  $\text{Cr}^{3+}$  complex, the mixture of the weighed solid  $\text{CrCl}_3 \cdot 6\text{H}_2\text{O}$  and the ligand stock solution (1.05 equiv.) with pH adjusted to *ca.* 6 with diluted aq.  $\text{NH}_3$  was heated in a tightly closed vial at 90 °C for 5 d. The  $\text{Fe}^{3+}$  complex was prepared by mixing the stock solution of  $\text{Fe}(\text{NO}_3)_3$  (concentration determined by iodometry) and the ligand stock solution (1.05 equiv.), pH adjustment to *ca.* 5 with diluted aq.  $\text{NH}_3$  and heating at 90 °C in a tightly closed vial overnight. Before measurement, *t*-BuOH (10  $\mu\text{l}$ ) was added to 350  $\mu\text{l}$  of the buffered (pH 7.4) complex solution into an NMR tube, an insert tube containing 0.1% *t*-BuOH in  $\text{D}_2\text{O}$  was inserted and the  $^1\text{H}$  NMR spectra were acquired. In the case of the  $\text{Fe}^{2+}$  complex, a fast formation of a colloidal precipitate was observed when handling the solution on air and, therefore, the complex was prepared under an Ar atmosphere, the solution was filtered through a microfilter and measured immediately.

Samples of the metal complexes of  $\text{H}_3\text{notp}^{\text{tfe}}$  for  $T_1$  and  $T_2$  NMR experiments were prepared in 1 ml vials by mixing the ligand stock solution (500  $\mu\text{l}$ ) with the stock solution (10  $\mu\text{l}$ ) of the appropriate metal salt containing 0.9 equiv. of the metal ion (*i.e.*  $\text{Mg}(\text{ClO}_4)_2$ ,  $\text{CrCl}_3$ ,  $\text{MnCl}_2$ ,  $\text{FeCl}_3$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$ ,  $\text{CuCl}_2$  and  $\text{ZnCl}_2$ ). These stock solutions were prepared by dissolution of 9 equiv. of the respective metal salts in water (100  $\mu\text{l}$ ). The pH of the mixtures was carefully adjusted by stepwise addition of diluted aq. NaOH to *ca.* 7 (in the case of the  $\text{Fe}^{3+}$  complex, diluted aq.  $\text{NH}_3$  was used). Then, the vials were closed and the mixtures were heated overnight at 50 °C (in the case of the  $\text{Cr}^{3+}$  and  $\text{Fe}^{3+}$  complexes, the mixtures were heated at 90 °C for 5 d). After cooling, pH was adjusted to 7.4 by diluted aq.  $\text{NH}_3$  (7.5 in the case of the  $\text{Mg}^{2+}$ - $\text{H}_3\text{notp}^{\text{tfe}}$  system).

Successful formation of the complexes was seen from the colour change ( $\text{Cr}^{3+}$ ,  $\text{Fe}^{3+}$ ,  $\text{Co}^{2+}$ ,  $\text{Ni}^{2+}$  and  $\text{Cu}^{2+}$ ) and was con-

firmed by NMR spectroscopy (Tables S1 and S2<sup>†</sup>) and mass spectrometry. The NMR and UV-Vis spectra of the complexes are shown in Fig. S8–S25.<sup>†</sup>

### Electrochemical study

The stock solutions of the  $\text{H}_3\text{notp}^{\text{tfe}}$  complexes for electrochemical experiments were prepared analogously as solutions for NMR studies but starting from the ligand stock solution (exactly 1.000 ml) and the corresponding solid metal salt (exactly 0.9 equiv.;  $\text{CrCl}_3 \cdot 6\text{H}_2\text{O}$ ,  $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ ,  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ ,  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ ); The pH of the solutions was adjusted to 7.4.

The  $\text{H}_3\text{nota}$  complexes for the electrochemical experiments with the same metal ions were prepared and isolated in the solid form as described in the literature (or by analogous procedures).<sup>52</sup> The solids were dissolved in water before the measurement.

Cyclic voltammetry was performed using a potentiostat Polarographic analyzer PA 3 equipped with an XY writer (Laboratorní přístroje Praha). A three-electrode setup was used. Working electrodes were a hanging mercury drop electrode (HMDE) or platinum disc electrode; a saturated calomel electrode (SCE) was used as the reference electrode. Platinum wire with a plate was used as the auxiliary (counter) electrode. Among the several aqueous supporting electrolytes tested (0.1 M  $\text{NaH}_2\text{PO}_4/\text{Na}_2\text{HPO}_4$  buffer with pH 7.4, 0.05 M  $\text{LiClO}_4$ , 0.05 M  $(\text{NH}_4)\text{ClO}_4$ , 0.05 M  $(\text{NET}_4)\text{ClO}_4$ , 0.05 M aq.  $\text{LiClO}_4$  was chosen due to the widest measurement window [+0.4–(-2.2) V

and +1.5–(–0.9) V for the HMDE and Pt electrode, respectively, vs. SCE]. For each measurement, 0.05 M aq. LiClO<sub>4</sub> (10 ml) was deoxygenated by bubbling argon through the solution in the measuring cell for several minutes; the absence of dissolved oxygen was confirmed by the measurement of a blank scan. Then, an appropriate volume of the stock solution of the studied H<sub>3</sub>notp<sup>tfc</sup> complex or weighed amount of the solid H<sub>3</sub>nota complex was added to reach a concentration of 1–4 mM for the complexes, and the solution was shortly deoxygenated again before the start of the electrochemical experiment.

Spectro-electrochemical experiments were performed using an optically transparent thin-layer electrochemical cell (OTTLE cell) assembled from a Pt mesh working electrode, Pt mesh auxiliary electrode and Ag wire as the reference electrode placed in a thin layer (optical path 0.2 mm) between two quartz windows.<sup>53</sup> Electrodes were connected to a potentiostat WaveDriver 10 (Pine research) driven by Aftermath 1.6 software. The OTTLE cell was placed into a UV-Vis spectrophotometer UV-18010 (Shimadzu).

Electrosynthesis of the [Co<sup>III</sup>(notp<sup>tfc</sup>)] complex was performed in an H-shaped electrochemical cell with a fine frit placed in the middle of the horizontal part connecting two vertical tubes. One tube was equipped with the auxiliary electrode (Pt wire with a plate) and was filled with 0.05 M LiClO<sub>4</sub>. The second tube contained the working electrode (Pt wire with a plate). The experiment was performed starting from 5 mM solution of the [Co<sup>II</sup>(notp<sup>tfc</sup>)]<sup>–</sup> complex in 0.05 M LiClO<sub>4</sub>.

### Potentiometric study

The methodology of potentiometric titrations and processing of the experimental data were analogous to those previously reported.<sup>47,54</sup> The ligand stock solution was prepared by dissolution of TFA-free H<sub>3</sub>notp<sup>tfc</sup> (600 mg) in a 50 ml volumetric flask. The exact ligand concentration (19.2 mM) was determined by <sup>19</sup>F qNMR using standardized aq. solution of TFA similarly as it was used previously.<sup>47</sup> This value agreed well with the value calculated during the fitting of the protonation constants (19.38 mM, difference <1%) which was used for the calculations of the constants.

Potentiometric titrations were carried out in a vessel thermostatted to 25 ± 0.1 °C. The titrations of the free ligand and systems containing Mg<sup>2+</sup>, Ca<sup>2+</sup>, Mn<sup>2+</sup>, Cu<sup>2+</sup> and Zn<sup>2+</sup> were performed in the –log[H<sup>+</sup>] range 1.6–12.1. The concentration of the ligand in the titration vessel was ca. 0.004 M, ligand-to-metal ratio 1 : 0.95, ionic strength 0.1 M (NMe<sub>4</sub>)Cl and starting volume ca. 5 ml. An equilibrium in the systems Co<sup>2+</sup>–H<sub>3</sub>notp<sup>tfc</sup> and Ni<sup>2+</sup>–H<sub>3</sub>notp<sup>tfc</sup> was established slowly and, therefore, the out-of-cell method was used in these cases. Each solution corresponding to one titration point was prepared in a tube with a ground joint (pH 1.6–6.5, three titrations with 15 points, starting volume ca. 1 ml, the same concentrations as used in a common titration) and the solutions were left to equilibrate at room temperature for one week. The overall protonation constants β<sub>h</sub> are concentration constants and are defined by β<sub>h</sub> = [H<sub>h</sub>L]/([H]<sup>h</sup>·[L]) (stepwise protonation constants

are defined as log K<sub>1</sub> = log β<sub>1</sub>; log K<sub>h</sub> = log β<sub>h</sub> – log β<sub>h–1</sub>). The overall stability constants are defined by the general equation β<sub>hml</sub> = [M<sub>m</sub>H<sub>h</sub>L<sub>l</sub>]/([M]<sup>m</sup>·[H]<sup>h</sup>·[L]<sup>l</sup>). Here, the formation of only M : L 1 : 1 complexes (m = l = 1) was considered. The water ion product, pK<sub>w</sub> 13.81, and stability constants of M<sup>2+</sup> – OH<sup>–</sup> systems were taken from the literature.<sup>55</sup> The constants (with their standard deviations) were calculated with program package OPIUM (Table S3†).

### Single-crystal X-ray diffraction study

**Preparation of single crystals.** The single crystals of (NH<sub>4</sub>)<sub>3</sub>[Mn(notp<sup>tfc</sup>)]Cl<sub>2</sub>·3H<sub>2</sub>O and (NH<sub>4</sub>)<sub>2</sub>[Cu(notp<sup>tfc</sup>)]Cl·3H<sub>2</sub>O were prepared by neutralization of an aq. solution containing equimolar amounts of the ligand and MCl<sub>2</sub> (M = Mn, Cu) with diluted aq. NH<sub>3</sub> to pH ca. 7 followed by a slow evaporation. Single crystals of [Mn(H<sub>2</sub>O)<sub>6</sub>][Mn(notp<sup>tfc</sup>)]<sub>2</sub>·18H<sub>2</sub>O were obtained by a similar procedure but an excess of MnCl<sub>2</sub> was used and some Mn(OH)<sub>2</sub> was filtered off before the solvent evaporation. The crystals of (NH<sub>4</sub>)<sub>2</sub>[Co(notp<sup>tfc</sup>)]·3.5H<sub>2</sub>O, (NH<sub>4</sub>)<sub>2</sub>[Cu(notp<sup>tfc</sup>)]·3.5H<sub>2</sub>O and [Mg(H<sub>2</sub>O)<sub>6</sub>][Ni(notp<sup>tfc</sup>)]<sub>2</sub>·12H<sub>2</sub>O were prepared from the corresponding aq. solutions of the (NH<sub>4</sub>)<sub>2</sub>[M(notp<sup>tfc</sup>)] complexes by the slow vapour diffusion of EtOH. The ammonium salts (NH<sub>4</sub>)<sub>2</sub>[M(notp<sup>tfc</sup>)] (M = Co, Cu) were obtained by reaction of the ligand with a slight excess of freshly precipitated M(OH)<sub>2</sub> followed by chromatography of the formed complex on silica using aq. NH<sub>3</sub>:EtOH in a 1 : 10 mixture as an eluent; under these conditions, the excess of free M<sup>2+</sup> was kept at the top of the column. In the case of [Mg(H<sub>2</sub>O)<sub>6</sub>][Ni(notp<sup>tfc</sup>)]<sub>2</sub>·12H<sub>2</sub>O, the ammonium salt obtained by chromatography was crystallized by concentration of the aq. solution in the presence of an excess of MgCl<sub>2</sub> (10 equiv.). The single crystals of [Co(H<sub>2</sub>O)<sub>6</sub>][Co(notp<sup>tfc</sup>)]<sub>2</sub>·14.25H<sub>2</sub>O·0.75MeOH were prepared by saturation of the ligand solution with an excess of freshly precipitated Co(OH)<sub>2</sub>, filtration, concentration and a slow vapour diffusion of MeOH into the complex solution. The single crystals of Na<sub>3</sub>[Co(notp<sup>tfc</sup>)]<sub>2</sub>Br·3Me<sub>2</sub>CO were prepared by neutralization of an equimolar aq. solution of the ligand and CoBr<sub>2</sub> with NaOH to pH ca. 7, concentration and a slow vapour diffusion of acetone. The single crystals of [ZnCl(H<sub>2</sub>O)<sub>3</sub>][Zn(notp<sup>tfc</sup>)]<sub>2</sub>·2H<sub>2</sub>O were obtained by mixing the ligand and an excess of ZnCl<sub>2</sub>, neutralization with diluted aq. NH<sub>3</sub> to pH ca. 5. and a slow concentration in air.

**General procedure for data acquisition and treatment.** The diffraction data were collected using a Bruker D8 VENTURE Duo diffractometer with an IμS micro-focus sealed tube using Cu-K<sub>α</sub> radiation (λ 1.54178 Å) or Mo-K<sub>α</sub> radiation (λ 0.71073 Å). Data were analysed using the SAINT software package (Bruker AXS Inc., 2015–2019). Data were corrected for absorption effects using the multi-scan method (SADABS).<sup>57</sup> All structures were solved by direct methods (SHELXT2014)<sup>58</sup> and refined using full-matrix least-squares techniques (SHELXL2017).<sup>59</sup> The details of the structure refinements are given in the ESI.† For overview of the experimental crystallographic data, see Table S4.† The cif-files of all structures reported here have been deposited in the Cambridge Crystallographic Data Centre (CCDC 2327147–2327158†).

## Results and discussion

### Synthesis of the ligand H<sub>3</sub>notp<sup>tfe</sup>

Synthesis of the studied ligand H<sub>3</sub>notp<sup>tfe</sup> (H<sub>3</sub>L) was performed as shown in Scheme 1.

The synthesis of the starting (2,2,2-trifluoroethyl)phosphinic acid was reported previously;<sup>47</sup> however, the use of commercial 2,2,2-trifluoroethyl iodide for an Arbuzov-type reaction with bis(trimethylsilyl)hypophosphite resulted in the presence of hydroiodic acid in the final mixture that complicated further purifications.<sup>47</sup> Therefore, we optimized the synthesis using 2,2,2-trifluoroethyl bromide. This compound was prepared by reaction of 2,2,2-trifluoroethyl-tosylate<sup>49</sup> with KBr in boiling anhydrous diethyleneglycol (boiling point 244 °C).<sup>50</sup> However, the synthesis needs non-trivial apparatus as the product is volatile (boiling point 26 °C) (see Experimental and Fig. S2†).

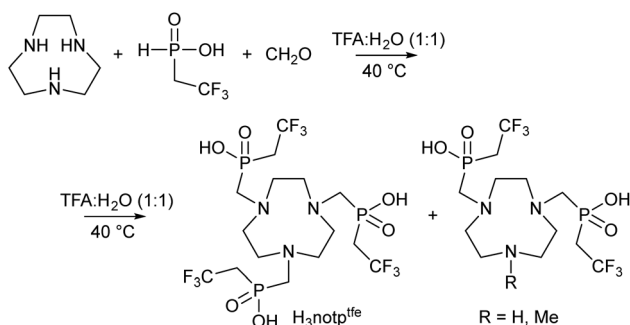

A Mannich-type reaction between tacn, (2,2,2-trifluoroethyl)phosphinic acid and paraformaldehyde was performed in a strong acid solution (50% v/v aq. TFA) at 40 °C. It was found that only a slight excess of (2,2,2-trifluoroethyl)phosphinic acid (3.1 equiv.) and paraformaldehyde (3.5 equiv.) is sufficient to reach almost quantitative conversion according to the <sup>19</sup>F and <sup>31</sup>P NMR spectra. Only a small extent of oxidation of (2,2,2-trifluoroethyl)phosphinic acid to (2,2,2-trifluoroethyl)phosphonic acid and formation of hydroxymethyl-(2,2,2-trifluoroethyl)phosphinic acid were observed under these conditions. The ligand H<sub>3</sub>notp<sup>tfe</sup> behaves as a strong acid and can be eluted from a strong cation exchange resin using water. However, its elution is only slightly slowed down compared to the simple acids present in the mixture [TFA, (2,2,2-trifluoroethyl)phosphonic acid, hydroxymethyl-(2,2,2-trifluoroethyl)phosphinic acid, an excess of starting (2,2,2-trifluoroethyl)phosphinic acid]. Traces of macrocyclic by-products with two phosphinic acid pendant arms (a twice-substituted intermediate and its *N*-methylated derivative, Scheme 1) were kept on the resin and could be eluted using 5% aq. ammonia solution. The ligand H<sub>3</sub>notp<sup>tfe</sup> was further purified by repeated chromatography on silica with conc. aq. NH<sub>3</sub>:EtOH 1:25 as the mobile phase to get a non-stoichiometric ammonium salt or by flash chromatography on a reverse phase column using a water:acetonitrile gradient containing 0.1% TFA as a modifier

to obtain non-stoichiometric trifluoroacetate. The ammonium salt of the ligand can be converted to the free ligand H<sub>3</sub>notp<sup>tfe</sup> on a strong cation exchange resin; ammonium cations stay on the column and the acidic form of H<sub>3</sub>notp<sup>tfe</sup> is eluted with water. In the case of the H<sub>3</sub>notp<sup>tfe</sup>-TFA adduct, a similar procedure can be used; however here, TFA is eluted only slightly earlier than the free H<sub>3</sub>notp<sup>tfe</sup> ligand and, thus, the procedure must be repeated to remove TFA completely. The ligand was isolated as a hygroscopic thick semi-solid glassy material, which complicates further analytical work. Therefore, concentrations of its stock solutions had to be determined independently by <sup>19</sup>F qNMR using the addition of a known amount of standardized TFA solution.

### Equilibrium studies

To study the acid-base behaviour of H<sub>3</sub>notp<sup>tfe</sup> and the stability of its complexes, potentiometric titrations were employed. Two protonation constants were calculated from the titration data acquired in the pH range 1.6–12.1. Tables 1 and S3† list the results together with data reported for related ligands. The observed protonation steps correspond to the protonations of the amino groups of the tacn skeleton. Going from the fully deprotonated species, the first protonation proceeds in the alkaline region (log *K*<sub>1</sub> > 10) as it is common for other tacn-based ligands; the observed value falls into a range of values for other tacn-tris(phosphinic acid) derivatives (Table 1).<sup>60–62</sup> Compared to the acetate (H<sub>3</sub>nota) and phosphonate (H<sub>6</sub>notp) derivatives (Fig. 1), the basicity of H<sub>3</sub>notp<sup>tfe</sup> is lower due to the electron-withdrawing characteristic of the phosphinate groups.<sup>63</sup> The protonation constant describing the second protonation step also corresponds well to those of other tacn-tris(phosphinic acid) derivatives (Table 1). Further protonations lay below the pH range accessible by potentiometry pointing to the strong acidity of the phosphinic acid groups. The calculated distribution diagram of differently protonated H<sub>3</sub>notp<sup>tfe</sup> species is shown in Fig. S26.†

The thermodynamic stabilities of the complexes with selected alkaline earth (Mg<sup>2+</sup>, Ca<sup>2+</sup>) and transition (Mn<sup>2+</sup>, Co<sup>2+</sup>, Ni<sup>2+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup>) metal ions were studied in the M<sup>2+</sup>-H<sub>3</sub>notp<sup>tfe</sup> systems using a slight ligand excess. Except for Co<sup>2+</sup> and Ni<sup>2+</sup>, complexation of all metal ions was fast enough for conventional potentiometry. The systems containing Co<sup>2+</sup>/Ni<sup>2+</sup> ions were studied by the out-of-cell method. The system containing Fe<sup>2+</sup> cannot be studied by this method as some precipitate is irreversibly formed during the titration. In general, besides formation of the [M(notp<sup>tfe</sup>)]<sup>-</sup> complexes, the formation of hydroxido-complexes [M(notp<sup>tfe</sup>)(OH)]<sup>2-</sup> was observed in strongly alkaline solutions pointing to the weak nucleophilicity of the pendant arm oxygen atoms which are replaced by the hydroxido ligand in a strongly alkaline solution (Table 1). It should be noted that potential formation of the hydroxido complexes of Co<sup>2+</sup> and Ni<sup>2+</sup> ions cannot be confirmed as the out-of-cell titration used to study the systems cannot be reliably performed up to the alkaline region. Stability constants of [M(notp<sup>tfe</sup>)]<sup>-</sup> complexes are similar to those found for other phosphinic acid derivatives and are significantly lower in compari-

Scheme 1 Synthesis of the studied ligand H<sub>3</sub>notp<sup>tfe</sup>.

**Table 1** Logarithms of ligand protonation constants ( $\log K_h$ ), stability constants of the studied metal complexes ( $\log \beta_{011}$ ) and protonation constants of hydroxidocomplexes ( $\log \beta_{011} - \log \beta_{-111}$ ) of  $H_3notp^{tfe}$ , and comparison with related ligands. Charges of the species are omitted for clarity; "L" means fully deprotonated form of the ligand

son with those of  $H_3nota$  and  $H_6notp$  as a result of a generally lower overall basicity of the donor sites in the phosphinate ligands.<sup>63</sup> The ligand  $H_3notp^{tfe}$  shows a slight selectivity for  $Mg^{2+}$  over  $Ca^{2+}$  analogously to other related derivatives; however, these biogenic ions are not fully complexed even in the strongly alkaline region (see Fig. 2 and S27†).

The complexes with the transition metal ions are much more stable than those of alkaline earth ions; the  $Mn^{2+}$  complex has the lowest stability among the studied transition metal ions and is fully formed above pH 7 (Fig. 2 and S28†). Complexes with  $Co^{2+}$ – $Zn^{2+}$  have comparable stability and the ligand shows almost no selectivity for the  $Cu^{2+}$  ion; so, the effect of Williams–Irving ordering is negligible. These metal ions are fully complexed at pH > 3; † an illustrative distribution diagram is shown in Fig. 2 and S29.†

The observed non-selectivity for the  $Cu^{2+}$  ion is consistent with the non-selectivity of other phosphorus-containing tacn-based ligands but it is in contrast to the selectivity observed for  $H_3nota$  (Table 1). Overall, the ligand  $H_3notp^{tfe}$  binds paramagnetic transition metal ions into stable complexes with a high selectivity over biogenic alkaline earths ions which is promising for potential *in vitro/in vivo* use.

### Magnetic properties of the complexes in solution

As the value of magnetic moment plays a significant role in the paramagnetic relaxation enhancement mechanism, we

**Fig. 2** Distribution diagrams of the  $M^{2+}$ – $H_3notp^{tfe}$  ( $=M^{2+}$ – $H_3L$ ) systems;  $c(M^{2+}) = c(H_3notp^{tfe}) = 0.004$  M,  $M = Mg, Mn$  and  $Cu$ . The abundances of the species formed in the  $Mg^{2+}$ – $H_3notp^{tfe}$  system are shown in red, those present in the  $Mn^{2+}$ – $H_3notp^{tfe}$  system are shown in green and those present in the  $Cu^{2+}$ – $H_3notp^{tfe}$  system are shown in blue. Dashed lines represent abundances of the free  $M^{2+}$  ions, full lines represent the  $[M^{II}(notp^{tfe})]^-$  species, and the dotted lines represent the  $[M^{II}(notp^{tfe})(OH)]^{2-}$  species.

determined the magnetic moments of the studied paramagnetic complexes in solution. As the  $\text{Mn}^{2+}/\text{Cu}^{2+}-\text{H}_3\text{notp}^{\text{tfe}}$  complexes are formed quickly (see Potentiometric study section), they were prepared by mixing the metal salt and ligand (in a slight excess) stock solutions, and adjusting the pH to 7.4. Solutions of the  $\text{Co}^{2+}$  and  $\text{Ni}^{2+}$  complexes were prepared analogously but the solutions were heated to 50 °C overnight to ensure full complexation. In the system containing  $\text{Fe}^{2+}$ , some colloidal precipitate was continuously formed; therefore, measurement of the magnetic moment was performed immediately after preparation of the solution under argon and filtration through a microfilter.

Solutions of the  $\text{Cr}^{3+}$  and  $\text{Fe}^{3+}$  complexes were prepared by the reaction of  $\text{CrCl}_3 \cdot 6\text{H}_2\text{O}$  (solid) or  $\text{Fe}(\text{NO}_3)_3$  (stock solution), respectively, with a slight excess of  $\text{H}_3\text{notp}^{\text{tfe}}$  after neutralization to pH 5–6 and heating at 90 °C for 5 d ( $\text{Cr}^{3+}$ ) or overnight ( $\text{Fe}^{3+}$ ). Surprisingly, attempts to prepare a solution of the  $\text{Co}^{3+}$  complex by reaction of the ligand with  $\text{Na}_3[\text{Co}(\text{CO}_3)_3]$  (a kinetically labile precursor commonly used for a direct preparation of trivalent cobalt complexes)<sup>69</sup> failed; the  $\text{Co}^{2+}$  complex was formed instead as identified by UV-Vis and  $^{19}\text{F}$  NMR spectroscopies.

Magnetic moments were determined using Evans' method<sup>70,71</sup> from the chemical shift difference of *t*-BuOH present in the solution of the complex with a known concentration and aq. solution in the insert cuvette and are listed in Table 2.

The values of  $\mu_{\text{eff}}$  clearly show that the complexes of  $\text{Mn}^{2+}$ ,  $\text{Fe}^{2+}/\text{Fe}^{3+}$  and  $\text{Co}^{2+}$  are high-spin and, thus, an overall ligand field induced by the  $(\text{notp}^{\text{tfe}})^{3-}$  anion is relatively small.

### Redox properties of the complexes

The redox behaviour of transition metal complexes of the "parent"  $\text{H}_3\text{nota}$  is well documented in the literature.<sup>52,72</sup> Redox potentials of the  $\text{M}^{3+/2+}-\text{H}_3\text{nota}$  systems are reported for  $\text{M} = \text{Cr}, \text{Mn}, \text{Fe}, \text{Co}$  and  $\text{Ni}$ , and values of some of them fall into a biologically relevant range (Table 3). The change of oxidation state governs electronic and magnetic properties of the ions, and can significantly alter the chemical shift of the  $^{19}\text{F}$  NMR signal and its relaxation properties. If the redox change can occur under *in vivo* conditions, the complex can be utilized as a redox-responsive probe.<sup>18</sup> Therefore, electrochemical studies of  $\text{H}_3\text{notp}^{\text{tfe}}$  complexes and analogous  $\text{H}_3\text{nota}$  complexes were performed to obtain directly comparable data as

**Table 2** Magnetic moments  $\mu_{\text{eff}}$  of the  $\text{M}^{2+}/\text{M}^{3+}-\text{H}_3\text{notp}^{\text{tfe}}$  complexes in aq. solution (pH 7.4)

<sup>a</sup> Hanging mercury drop electrode. <sup>b</sup> Platinum electrode. <sup>c</sup> No electrochemical process was observed.

data reported in the literature were sometimes acquired under different or unspecified conditions (electrode material, supporting electrolyte). Besides the metal ions mentioned above, we also studied the  $\text{Cu}^{2+}$  complex as the  $\text{Cu}^{2+}/\text{Cu}^+$  pair can also be employed as a redox probe.<sup>18</sup>

0.05 M aq.  $\text{LiClO}_4$  solution was chosen as the supporting electrolyte due to a wide measurement window [+0.4–(–2.2) and 1.5–(–0.9) V using the HMDE and Pt electrode, respectively, vs. SCE], and the complexes were studied by cyclic voltammetry (CV). The reversible behaviour of the  $\text{M}^{2+}/\text{M}^{3+}-\text{H}_3\text{notp}^{\text{tfe}}$  and  $\text{M}^{2+}/\text{M}^{3+}-\text{H}_3\text{nota}$  pairs was found for  $\text{M} = \text{Cr}, \text{Mn}, \text{Fe}$  and  $\text{Co}$  (Table 3). In contrast to the  $[\text{Ni}^{\text{II}}(\text{nota})]^-$  complex,  $[\text{Ni}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  cannot be oxidized to the  $[\text{Ni}^{\text{III}}(\text{notp}^{\text{tfe}})]$  complex in the accessible potential range.

In the case of the Mn-systems with both ligands, a further reversible process was observed which is attributable to the  $[\text{Mn}^{\text{IV}}(\text{L})]^+ / [\text{Mn}^{\text{III}}(\text{L})]$  redox pair. This behaviour was reported for the  $\text{Mn}^{2+}-\text{H}_3\text{nota}$  complex previously<sup>72</sup> but the reported potentials of 0.30 and 0.68 V for the  $[\text{Mn}^{\text{III}}(\text{nota})] / [\text{Mn}^{\text{II}}(\text{nota})]^-$  and  $[\text{Mn}^{\text{IV}}(\text{nota})]^+ / [\text{Mn}^{\text{III}}(\text{nota})]$  pairs, respectively, are not consistent with other literature data<sup>52</sup> and with our value; probably, the reported potentials were wrongly corrected for the SCE potential. To identify the species and to study their stabilities, a spectro-electrochemical study was performed. If the potential was increased in the range from 0.5 to 1.0 V, a d–d transition band centred at 470 nm gradually appeared (Fig. S30†), attributable to  $\text{Mn}^{3+}$  due to the one-electron oxidation of  $[\text{Mn}^{\text{II}}(\text{L})]^-$  and the formation of  $[\text{Mn}^{\text{III}}(\text{L})]$ , consistent with the results obtained by the CV study. Further oxidation (applied potential up to 1.8 V) led to a gradual increase in absorbance over the whole spectral range, with no distinguished absorption band (Fig. S31†). It was probably caused by the formation of a colloidal precipitate. Thus, one can conclude that the oxidation of  $[\text{Mn}^{\text{III}}(\text{L})]$  to  $[\text{Mn}^{\text{IV}}(\text{L})]^+$  is pseudo-reversible on the short CV timescale but the formed  $\text{Mn}^{\text{IV}}$ -species decomposes and colloidal  $\text{MnO}_2 \cdot n\text{H}_2\text{O}$  is formed during the longer spectro-electrochemical timescale.

The spectro-electrochemical reduction (applied potential from 0.5 to –0.8 V) of the  $[\text{Fe}^{\text{III}}(\text{notp}^{\text{tfe}})]$  complex led to the formation of  $[\text{Fe}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  as documented by the gradual spec-

tral change (Fig. S32†). The  $[\text{Fe}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  species was found to be stable on the given timescale (order of seconds); however as observed earlier, it decomposes on longer standing (see the Magnetic properties section).

The electro-synthetic oxidation (applied potential 1.1 V) of the  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex (characterized by three close low-intensity absorption bands centred around 520 nm) revealed the formation of the  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  complex (the appearance of two new intense d-d bands at 394 and 557 nm, as shown in Fig. S33†) which is stable in solution for at least several days.

The  $\text{Cu}^{2+}$  complexes of both  $\text{H}_3\text{notp}^{\text{tfe}}$  and  $\text{H}_3\text{nota}$  underwent irreversible two-electron reduction on HMDE as proved by the anodic peak corresponding to the oxidation of metallic copper; no electrochemical changes were observed using the Pt electrode. According to the measured values, the  $[\text{Cr}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex is a very strong reduction agent similar to  $[\text{Cr}^{\text{II}}(\text{nota})]^-$ , and its potential lies close to the reduction edge of HDME; such a value cannot be practically utilized in biological systems. However, the potentials of  $[\text{M}^{\text{III}}(\text{L})]/[\text{M}^{\text{II}}(\text{L})]^-$  pairs with  $\text{M} = \text{Mn}, \text{Fe}$  and  $\text{Co}$  lie in the biologically relevant range. Among them, the stability of the  $\text{Mn}^{2+}$  complex is not sufficient for utilization in biological systems (full complexation at  $\text{pH} > 7$ , see Potentiometric study section) and the  $[\text{Fe}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  species was found to be kinetically labile, so only the  $\text{Co}^{3+}/\text{Co}^{2+}-\text{H}_3\text{notp}^{\text{tfe}}$  redox pair is suitable for *in vitro/in vivo* utilization. Furthermore, the  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex is a high-spin paramagnetic species but the oxidized form  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  is a low-spin diamagnetic complex, which induces a very significant change in the  $^{19}\text{F}$  NMR spectra (see below). Therefore, we studied the corresponding redox process using chemical oxidizing/reducing agents. The  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  species can be prepared by chemical oxidation of  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  with  $\text{K}_2\text{S}_2\text{O}_8$  or  $\text{H}_2\text{O}_2$  (Fig. S33†). The  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  species can be reduced back to the  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex using  $\text{NaBH}_4$ ; other reducing agents tested –  $\text{N}_2\text{H}_4$ ,  $\text{NH}_2\text{OH}$ ,  $\text{Na}_2\text{S}_2\text{O}_4$  – caused no reaction. It should be further highlighted that the reaction of  $\text{H}_3\text{notp}^{\text{tfe}}$  with  $\text{Na}_3[\text{Co}^{\text{III}}(\text{CO}_3)_3]$  afforded  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  and not the expected  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  complex. Therefore, although the  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  species is a relatively strong oxidation agent ( $E_3^0 + 0.95$  V vs. SCE, Table 3), some kinetic barrier plays a role in the tested chemical reductions, probably due to a full wrapping of the central metal ion with the ligand which prevents a close contact with a reduction agent. A comparison of the scaled UV-Vis spectra of  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  and  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  is shown in Fig. 3.

### Solid-state structures of the complexes

The  $\text{H}_3\text{nota}$ -like ligands usually wrap the metal ions in a hexadentate fashion. Three nitrogen atoms of the tacn skeleton form a basal  $\text{N}_3$ -plane making one face of the coordination polyhedron, and the oxygen atoms of three pendant arms form a parallel upper  $\text{O}_3$ -plane. Formation of the chelate rings upon a coordination of the tacn unit results in a clock-wise or anti-clock-wise torsion on the ethylene groups connecting the coordinated nitrogen atoms (*i.e.*, in the Newman projection of

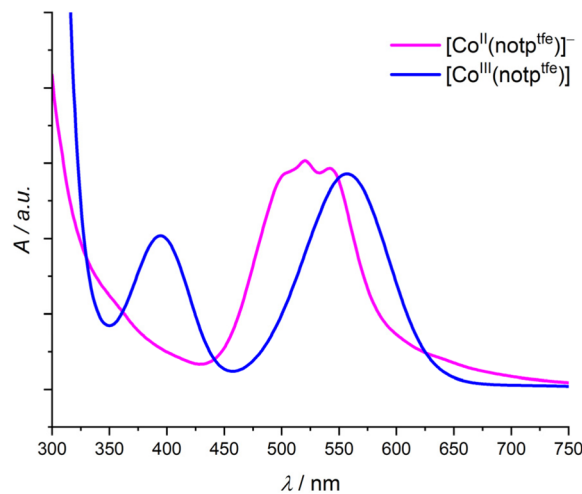

Fig. 3 Comparison of the UV-Vis spectra of  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  and  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complexes. Spectra are arbitrarily scaled. Extinction coefficients in  $\text{dm}^3 \text{mol}^{-1} \text{cm}^{-1}$ :  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$ :  $\epsilon(502 \text{ nm}) 16$ ,  $\epsilon(520 \text{ nm}) 17$ ,  $\epsilon(541 \text{ nm}) 16$ ;  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$ :  $\epsilon(394 \text{ nm}) 68$ ,  $\epsilon(557 \text{ nm}) 92$ .

the formal ethylene-diamine fragment, it depends on mutual positions of the C–N bonds of the front and rear carbon atoms, respectively); such conformations are denoted as  $\delta$  or  $\lambda$ . All three chelate rings formed in the macrocyclic part have to adopt the same geometry due to steric hindrances, *i.e.* one of two possible macrocycle conformations  $\delta\delta\delta$  or  $\lambda\lambda\lambda$  is formed. The pendant arm coordination leads to a torsion of the pendant arm with respect to the (pseudo)trigonal axis. Here, stereodescriptors  $\Delta$  and  $\Lambda$  are used for clockwise and anti-clockwise arrangements, respectively [*i.e.*, differing in mutual positions of the O and N atoms belonging to the individual pendant arms in a view along the (pseudo)trigonal axis from the top to the bottom]. If the complex molecule has (pseudo) trigonal symmetry, all pendants are twisted in the same direction. A combination of both rotations leads to the formation of two diastereomeric pairs of enantiomers,  $\Delta\Delta\Delta\lambda\lambda\lambda + \Lambda\Lambda\Lambda\delta\delta\delta$  and  $\Delta\Delta\Delta\delta\delta\delta + \Lambda\Lambda\Lambda\lambda\lambda\lambda$  (hereafter for simplicity denoted as  $\Delta\lambda + \Lambda\delta$  and  $\Delta\delta + \Lambda\lambda$ ). Analogous diastereoisomerism is well-documented in the complexes of  $\text{H}_4\text{dota}$ -like ligands (Fig. 1) where it leads to the square-antiprismatic (SA isomer,  $\Delta\lambda + \Lambda\delta$ , real pendant torsion  $>35^\circ$ ) and the twisted-square-antiprismatic (TSA isomer,  $\Delta\delta + \Lambda\lambda$ , real pendant torsion  $<30^\circ$ ) geometries.<sup>63,73–80</sup> Similarly to the complexes of  $\text{H}_4\text{dota}$ -like ligands, the diastereoisomers of the complexes of  $\text{H}_3\text{nota}$ -like ligands also differ in a mutual twist of the  $\text{N}_3$ - and  $\text{O}_3$ -planes. The larger twist found in the  $\Delta\lambda + \Lambda\delta$  isomer leads to a shorter separation of the  $\text{N}_3$ - and  $\text{O}_3$ -planes and to a geometry closer to an octahedron (OC). The  $\Delta\delta + \Lambda\lambda$  conformations lead to the twisted-trigonal-antiprismatic (TTA) arrangement with a somewhat larger distance between the  $\text{N}_3$ - and  $\text{O}_3$ -planes. In the case of the  $\text{H}_3\text{notp}^{\text{tfe}}$  ligand, a further source of isomerism comes also from the absolute (*R/S*) configuration of the phosphorus atom upon coordination of the phosphinate group. Three pendant arms with potentially independent

*R/S*-isomerism give rise to a number of isomers (Fig. 4), similarly as observed for the phosphinate analogues of  $H_4\text{dota}$ .<sup>81–83</sup>

Two  $\text{Mn}^{2+}$  phases were obtained where the central  $\text{Mn}^{2+}$  ion has the TTA coordination sphere. The absolute configuration on a phosphorus atom of all coordinated pendant phosphinate groups in the complex molecule is the same (in the latter compound forced due to the crystallographic trigonal symmetry of the space group,  $R\bar{3}$ ), resulting in the presence of the enantio-

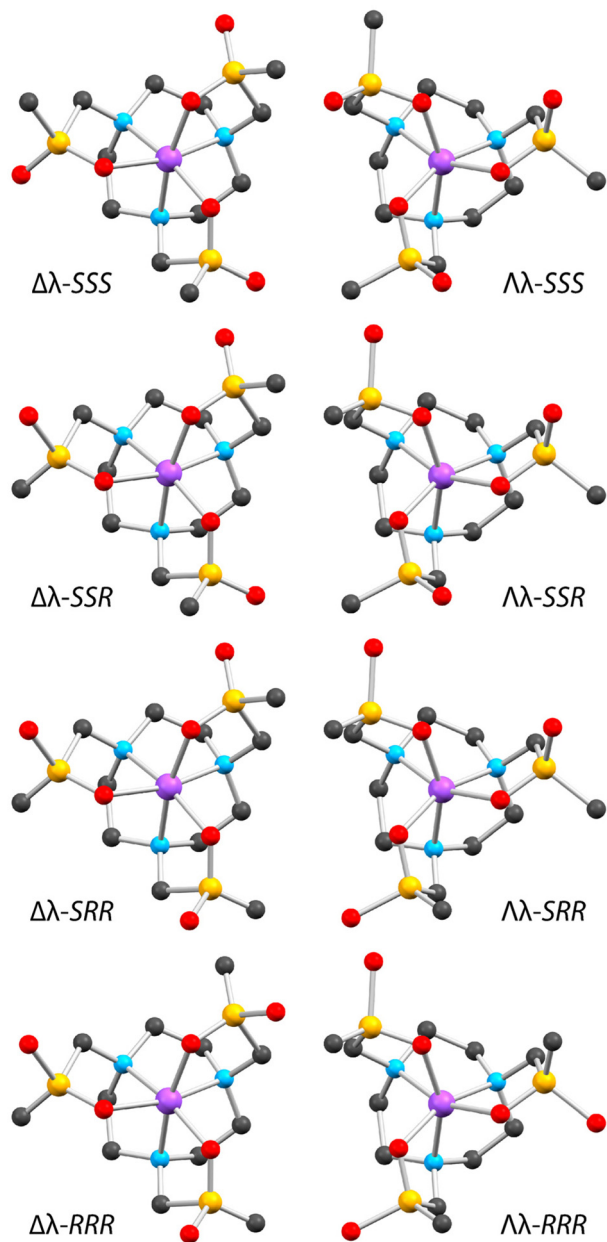

meric pair  $\Delta\delta$ -SSS and  $\Lambda\lambda$ -RRR in both structures. Selected relevant geometric parameters are listed in Tables 4 and S5<sup>†</sup> and molecular structures of the complex species are shown in Fig. 5 and 6.

The coordination cages are relatively large compared to other complexes (see below) as evidenced by the distance between the  $\text{N}_3$ - and  $\text{O}_3$ -planes (2.9 and 2.8 Å, respectively). It is caused by the long length of the N–Mn coordination bonds. The large separation of the planes leads also to a relatively small twist angle between the planes (*i.e.* pendant arm rotation, *ca.* 8° and 24° for the complex anions in  $(\text{NH}_4)_3[\text{Mn}(\text{notp}^{\text{tfe}})]\text{Cl}_2 \cdot 3\text{H}_2\text{O}$  and  $[\text{Mn}(\text{H}_2\text{O})_6][\text{Mn}(\text{notp}^{\text{tfe}})]_2 \cdot 18\text{H}_2\text{O}$  phases, respectively). In the crystal structure of  $[\text{Mn}(\text{H}_2\text{O})_6][\text{Mn}(\text{notp}^{\text{tfe}})]_2 \cdot 18\text{H}_2\text{O}$ , two  $[\text{Mn}(\text{notp}^{\text{tfe}})]^-$  anions are head-to-head connected to the central  $[\text{Mn}(\text{H}_2\text{O})_6]^{2+}$  cation through hydrogen bonds (Fig. 6); a similar structural motif was also found in some other crystal structures (see below).

Several  $\text{Co}^{2+}$ -containing phases were obtained and, surprisingly, different diastereoisomers of the  $[\text{Co}(\text{notp}^{\text{tfe}})]^-$  anion were found. In the crystal structure of  $(\text{NH}_4)[\text{Co}(\text{notp}^{\text{tfe}})] \cdot 3.5\text{H}_2\text{O}$ , the  $\Delta\lambda$ -SSS and  $\Lambda\delta$ -RRR enantiomers with the OC geometry were found (Fig. 7 and S37<sup>†</sup>). In the structure of  $[\text{Co}(\text{H}_2\text{O})_6][\text{Co}(\text{notp}^{\text{tfe}})]_2 \cdot 14.25\text{H}_2\text{O} \cdot 0.75\text{MeOH}$  the  $\Delta\delta$ -SSS and  $\Lambda\lambda$ -RRR enantiomeric pairs with TTA geometries were found; for an example, see Fig. 8. These complex anions are connected to the  $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$  cation through the hydrogen bonds (Fig. S38<sup>†</sup>) similarly as it was observed in the crystal structure of  $[\text{Mn}(\text{H}_2\text{O})_6][\text{Mn}(\text{notp}^{\text{tfe}})]_2 \cdot 18\text{H}_2\text{O}$  discussed above, although the compounds are not isostructural. In contrast to the structures of the other  $\text{Co}^{2+}$  phases, the sodium salt  $\text{Na}_3[\text{Co}(\text{notp}^{\text{tfe}})]_2\text{Br} \cdot 3\text{Me}_2\text{CO}$  presents a TTA enantiomeric  $\Delta\delta$ -RRR/ $\Lambda\lambda$ -SSS pair (Fig. 8 and S39<sup>†</sup>). Selected relevant geometric parameters for the structures are listed in Tables 4 and S5.<sup>†</sup>

The  $\text{Ni}^{2+}$  complex was successfully crystallized as  $[\text{Mg}(\text{H}_2\text{O})_6][\text{Ni}(\text{notp}^{\text{tfe}})]_2 \cdot 12\text{H}_2\text{O}$  in the space group  $R\bar{3}$  and with the lattice parameters close to those of  $[\text{Mn}(\text{H}_2\text{O})_6][\text{Mn}(\text{notp}^{\text{tfe}})]_2 \cdot 18\text{H}_2\text{O}$ ; however, the compounds are not isostructural. As in the  $[\text{Mn}(\text{H}_2\text{O})_6][\text{Mn}(\text{notp}^{\text{tfe}})]_2 \cdot 18\text{H}_2\text{O}$  and  $[\text{Co}(\text{H}_2\text{O})_6][\text{Co}(\text{notp}^{\text{tfe}})]_2 \cdot 14.25\text{H}_2\text{O} \cdot 0.75\text{MeOH}$  phases, two  $[\text{Ni}(\text{notp}^{\text{tfe}})]^-$  anions are head-to-head connected to the central hexaaqua unit *via* hydrogen bonds (Fig. S40<sup>†</sup>). The  $[\text{Ni}(\text{notp}^{\text{tfe}})]^-$  species form an octahedral  $\Lambda\delta$ -RRR/ $\Delta\lambda$ -SSS pair (Fig. 9). For geometric parameters, see Tables 4 and S5.<sup>†</sup>

In the case of the  $\text{Cu}^{2+}$  complex, two different phases were isolated in the solid state. The compound  $(\text{NH}_4)[\text{Cu}(\text{notp}^{\text{tfe}})] \cdot 3.5\text{H}_2\text{O}$  is isostructural with  $(\text{NH}_4)[\text{Co}(\text{notp}^{\text{tfe}})] \cdot 3.5\text{H}_2\text{O}$  and even an analogous disorder was found (see the ESI<sup>†</sup>). The  $\Delta\lambda$ -SSS/ $\Lambda\delta$ -RRR enantiomers with the octahedral geometry were found (Fig. S41 and S42<sup>†</sup>). In the other phase of composition  $(\text{NH}_4)_2[\text{Cu}(\text{notp}^{\text{tfe}})]\text{Cl} \cdot 3\text{H}_2\text{O}$ , only two pendant arms are coordinated and they are turned in mutually opposite directions (Fig. 10). Centrosymmetry of the space group ( $P\bar{1}$ ) leads formally to  $\Delta\lambda$ - $\lambda\lambda$ -SR/ $\Lambda\delta$ - $\delta\delta$ -RS enantiomers. Very similar pentacoordinated geometry was previously reported for the  $\text{Cu}^{2+}$  complexes of  $\text{H}_6\text{notp}$  and  $\text{H}_3\text{notp}^{\text{Ph}}$

**Fig. 4** Possible diastereoisomers of  $\text{H}_3\text{notp}^{\text{tfe}}$  complexes; only one of the enantiomers of each diastereoisomer is shown. All shown enantiomers have the  $\lambda\lambda\lambda$  conformations of the macrocycle, the other enantiomers have the  $\delta\delta\delta$  conformations. Left column: the OC species; right column: the TTA species. Colour code: metal ion – magenta, phosphorus – orange, oxygen – red, nitrogen – light blue, carbon – dark grey.

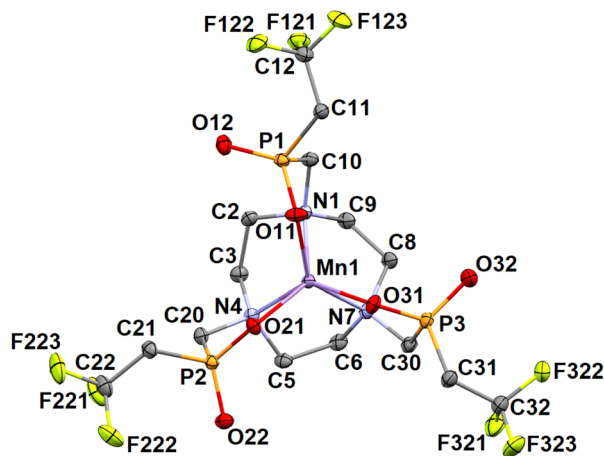

Fig. 5 Molecular structure of the  $[\text{Mn}(\text{notp}^{\text{tfe}})]^-$  anion with the  $\Delta\delta$ -SSS TTA geometry found in the crystal structure of  $(\text{NH}_4)_3[\text{Mn}(\text{notp}^{\text{tfe}})]\text{Cl}_2 \cdot 3\text{H}_2\text{O}$ . Hydrogen atoms are omitted for clarity.

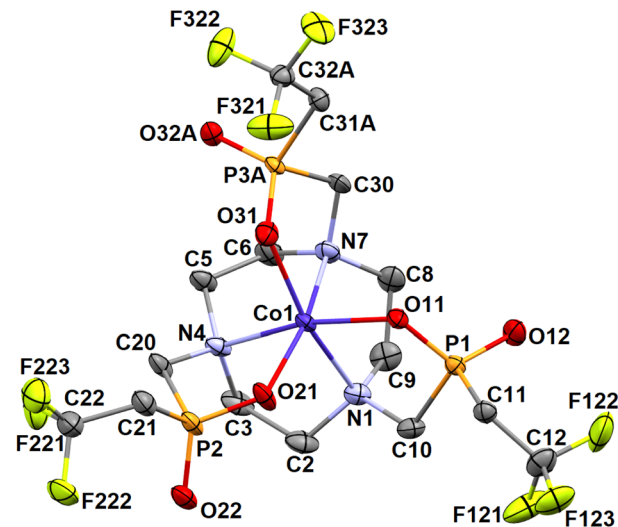

Fig. 7 Molecular structure of the  $[\text{Co}(\text{notp}^{\text{tfe}})]^-$  anion with the  $\Delta\lambda$ -SSS OC geometry found in the crystal structure of  $(\text{NH}_4)[\text{Co}(\text{notp}^{\text{tfe}})] \cdot 3.5\text{H}_2\text{O}$ . More abundant part of the disordered pendant arm (P3A and related atoms) is shown; for the disorder, see Fig. S37.† Hydrogen atoms are omitted for clarity.

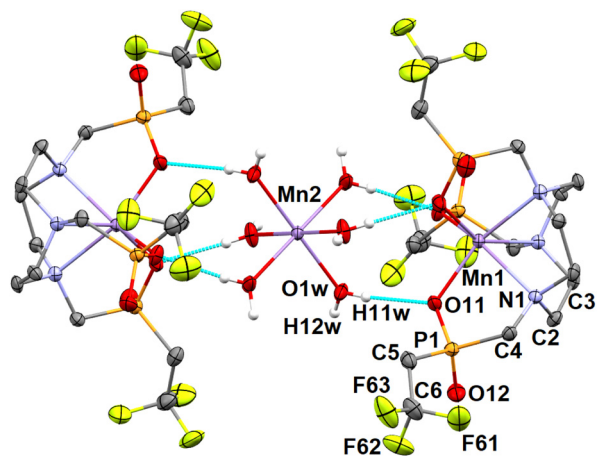

Fig. 6 Molecular structure of  $[\text{Mn}(\text{H}_2\text{O})_6][\text{Mn}(\text{notp}^{\text{tfe}})]_2$  fragment found in the crystal structure of  $[\text{Mn}(\text{H}_2\text{O})_6][\text{Mn}(\text{notp}^{\text{tfe}})]_2 \cdot 18\text{H}_2\text{O}$ . Intermolecular hydrogen bonds connecting two  $[\text{Mn}(\text{notp}^{\text{tfe}})]^-$  anions to the central  $[\text{Mn}(\text{H}_2\text{O})_6]^{2+}$  cation are shown in turquoise. Individual  $[\text{Mn}(\text{notp}^{\text{tfe}})]^-$  species adopt the  $\Delta\delta$ -SSS and  $\Delta\lambda$ -RRR TTA geometries. Carbon-bound hydrogen atoms are omitted for clarity.

(Fig. 1).<sup>84,85</sup> Selected geometric parameters are listed in Tables 4 and S5.†

Octahedral species with  $\Delta\delta$ -RRR and  $\Delta\lambda$ -SSS geometry were also observed in the crystal structure of the  $\text{Zn}^{2+}$  complex,  $[\text{ZnCl}(\text{H}_2\text{O})_3][\text{Zn}(\text{notp}^{\text{tfe}})] \cdot 2\text{H}_2\text{O}$  (Fig. S43†). Here, the counter-cation  $[\text{ZnCl}(\text{H}_2\text{O})_3]^+$  is formed from the excess of  $\text{ZnCl}_2$  used in the reaction. For geometric parameters, see Tables 4 and S5.†

Overall, the twisted trigonally antiprismatic (TTA,  $\Delta\delta/\Delta\lambda$ ) geometry is preferred for the largest ion ( $\text{Mn}^{2+}$ ) as this geometry leads to a larger coordination cage ( $d_{\text{NQ}\cdots\text{OQ}}$  2.62–2.90 Å, Tables 4 and S5†). Smaller  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$  and  $\text{Zn}^{2+}$  ions form octahedral species (OC,  $\Delta\lambda/\Delta\delta$ ) with a shorter separation of the  $\text{N}_3$ - and  $\text{O}_3$ -planes (2.45–2.57 Å). The  $\text{Co}^{2+}$  ion of an intermediate

size can adopt both environments, differing in this parameter. The torsion angles of the pendant arms are consistently smaller for the TTA (7–36°, ideal value 30°) than for the OC (43–54°, ideal value 60°) arrangements. Similar structural features were also found for divalent transition metal complexes of the related ligands. All reported divalent complexes of  $\text{H}_3\text{notp}^{\text{Ph}}$  ( $\text{Co}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$  and  $\text{Zn}^{2+}$ ) adopt an OC geometry with the  $\text{N}_3$ - $\text{O}_3$  twist in the range 51–52°.<sup>86,87</sup> However, the  $\text{Mn}^{2+}$  complex of  $\text{H}_6\text{notp}$  also adopt the OC geometry but very distorted [twist 38°, distances from the centroids of the  $\text{N}_3$ - and  $\text{O}_3$ -planes, NQ and OQ, respectively, are  $d(\text{Mn}\cdots\text{NQ})$  1.64 Å,  $d(\text{Mn}\cdots\text{OQ})$  1.02 Å].<sup>88</sup>

The critical parameter influencing the relaxation rates of the  $^{19}\text{F}$  nuclei is the distance between the paramagnetic ion and the fluorine atoms. Therefore, this parameter is compiled in Table 4 together with selected geometric parameters of the coordination cages. It can be seen that the exact geometry of the coordination sphere influences the  $\text{M}\cdots\text{F}$  distance only negligibly – in the TTA species, the distances are only slightly longer (ca. 5.6–6.7 Å) when compared to the OC isomers (ca. 5.5–6.5 Å). Such distances fall in the range suggested to be relevant for a significant influence on the  $^{19}\text{F}$  NMR relaxation times.<sup>89</sup> Very similar mean  $\text{M}\cdots\text{F}$  lengths were observed also in the complexes of 1,8- $\text{H}_2\text{te}2\text{p}^{\text{tfe}}$  (cyclam-based ligand with the same pendant arms, Fig. 1) which were studied previously.<sup>47</sup>

### NMR spectral properties of the complexes

Measured NMR characteristics of the studied complexes are compiled in Tables 5, 6, S1 and S2.† A comparison of the  $^{19}\text{F}$  NMR spectra of transition metal complexes of  $\text{H}_3\text{notp}^{\text{tfe}}$  is shown in Fig. 11.

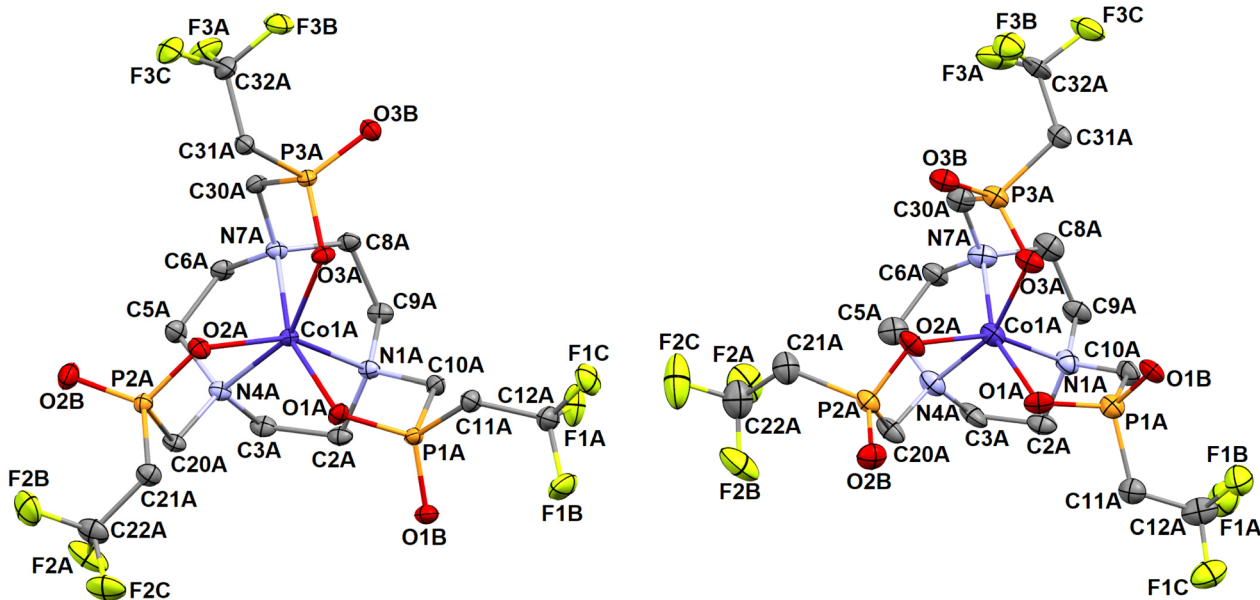

Fig. 8 Molecular structures of the  $[\text{Co}(\text{notp}^{\text{tfe}})]^-$  anion with the  $\lambda\lambda\text{-RRR}$  TTA geometry found in the crystal structure of  $[\text{Co}(\text{H}_2\text{O})_6][\text{Co}(\text{notp}^{\text{tfe}})]_2 \cdot 14.25\text{H}_2\text{O} \cdot 0.75\text{MeOH}$  (left) and that with the  $\lambda\lambda\text{-SSS}$  TTA geometry found in the crystal structure of  $\text{Na}_3[\text{Co}(\text{notp}^{\text{tfe}})]_2\text{Br} \cdot 3\text{Me}_2\text{CO}$  (right). Hydrogen atoms are omitted for clarity.

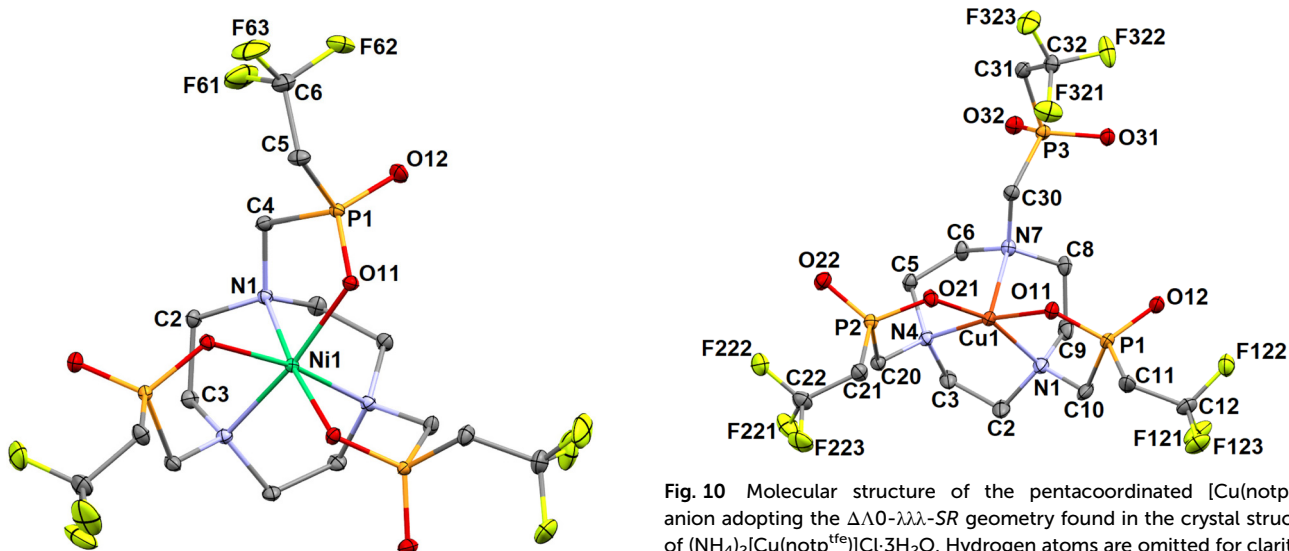

Fig. 9 Molecular structure of the  $[\text{Ni}(\text{notp}^{\text{tfe}})]^-$  anion with the  $\lambda\delta\text{-RRR}$  OC geometry found in the crystal structure of  $[\text{Mg}(\text{H}_2\text{O})_6][\text{Ni}(\text{notp}^{\text{tfe}})]_2 \cdot 12\text{H}_2\text{O}$ . Hydrogen atoms are omitted for clarity.

To study the solution structures of the complexes, the NMR spectra of diamagnetic ( $\text{Mg}^{2+}$ ,  $\text{Zn}^{2+}$ ) complexes also were acquired. The  $^{19}\text{F}$  NMR spectrum of the  $\text{Mg}^{2+}\text{-H}_3\text{notp}^{\text{tfe}}$  system at pH 7.5 fully agrees with the results of potentiometry – the spectrum revealed the presence of the well resolved signals of the free ligand and the complex in *ca.* 65 : 35 ratio (Fig. S8†). Besides these two species, some very minor signals were also observed, probably belonging to the complex species with

Fig. 10 Molecular structure of the pentacoordinated  $[\text{Cu}(\text{notp}^{\text{tfe}})]^-$  anion adopting the  $\Delta\Lambda\text{O-}\lambda\lambda\lambda\text{-SR}$  geometry found in the crystal structure of  $(\text{NH}_4)_2[\text{Cu}(\text{notp}^{\text{tfe}})]\text{Cl} \cdot 3\text{H}_2\text{O}$ . Hydrogen atoms are omitted for clarity.

different *R/S* configurations of the phosphinate pendant groups or to some species in which some of the pendant arms are uncoordinated. It indicates that the ligand and complex species are not in chemical exchange with respect to the NMR time scale, and, very probably, the major complex species has the  $C_3$ -symmetry. In the case of the  $\text{Zn}^{2+}\text{-H}_3\text{notp}^{\text{tfe}}$  system, a full complexation of the metal ion was expected on the basis of potentiometry. It was confirmed by the  $^{19}\text{F}$  and  $^{31}\text{P}$  NMR spectra (Fig. S23–S25†) where observation of only one symmetric signal points to the presence of only one enantiomeric pair of a single diastereoisomer (one combination of  $\Delta/\Lambda + \delta/\lambda$

**Fig. 11** Visual comparison of  $^{19}\text{F}$  NMR spectra of the studied transition metal complexes of  $\text{H}_3\text{notp}^{\text{tfe}}$  and free ligand. The inset shows spectra of diamagnetic  $\text{H}_3\text{notp}^{\text{tfe}}$  and  $[\text{Zn}(\text{notp}^{\text{tfe}})]^-$ .

+  $R/S$ ) in the solution; it is very probably the octahedral  $\Delta\lambda\text{-SSS}/\Lambda\delta\text{-RRR}$  species found in the solid state (see above). However, the  $^1\text{H}$  and  $^{13}\text{C}\{^1\text{H}\}$  NMR spectra showed a fast fluxionality of the complex species: only two unresolved broad signals were found in the  $^1\text{H}$  NMR spectrum at  $25\text{ }^{\circ}\text{C}$  (Fig. S21†). The signals remained broad even at  $5\text{ }^{\circ}\text{C}$  which precludes further study. In the  $^{13}\text{C}\{^1\text{H}\}$  NMR spectrum, two very broad signals of the macrocyclic carbon atoms were found but other carbon atoms showed well-resolved sharp signals (Fig. S22†).

For the  $\text{Cr}^{3+}$ ,  $\text{Mn}^{2+}$  and  $\text{Fe}^{3+}$  complexes, only  $^{19}\text{F}$  NMR signals can be detected; signals of the other nuclei fully vanished, probably due to the relatively slow electronic relaxation caused by the symmetric electronic state of the metal ions ( $t_{2g}^3$  for  $\text{Cr}^{3+}$ ,  $\text{HS-}d^5$  for the others). The  $^{19}\text{F}$  NMR signals of  $[\text{Cr}^{\text{III}}(\text{notp}^{\text{tfe}})]^-$  and  $[\text{Mn}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  are extremely broad ( $\nu_{1/2} \approx 2.0$  and  $\approx 4.6$  kHz at 565 MHz, respectively) whereas the  $^{19}\text{F}$  NMR signal of the  $[\text{Fe}^{\text{III}}(\text{notp}^{\text{tfe}})]^-$  complex is more narrow ( $\nu_{1/2} \approx 1.1$

kHz at 565 MHz) and can be easily measured. However, the longitudinal relaxation of the  $^{19}\text{F}$  NMR signals of all these complexes is extremely fast ( $T_1 < 1$  ms, Tables 5 and 6).

In contrast to the paramagnetic complexes discussed above, all  $^1\text{H}$ ,  $^{13}\text{C}$ ,  $^{19}\text{F}$  and  $^{31}\text{P}$  NMR spectra could be observed for the  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex. As several geometries of the complex were found in the solid state (see above), some dynamic equilibrium between the arrangements can be expected in the solution. However, there is only one symmetric (although broad) peak in the  $^{19}\text{F}/^{31}\text{P}$  NMR spectra and only one set of a  $^1\text{H}/^{13}\text{C}$   $\{^1\text{H}\}$  signal. Thus, fluxionality of the  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex species is probably very fast. In the  $^1\text{H}$  NMR spectra spreading over 200 ppm, 7 of the expected 8 signals were found (Fig. 12 and S13 $\dagger$ ) as the last signal was very close to the signal of the solvent (water/HDO) and overlapped; it was found by measuring the temperature dependence of the spectra (Fig. S13 $\dagger$ ). In the  $^{13}\text{C}\{^1\text{H}\}$  NMR spectra, all of the expected 5 signals were observed in the range from  $-500$  to  $+200$  ppm (Fig. 12 and S14 $\dagger$ ). A similar very large spectral  $^{13}\text{C}$  NMR range was observed previously for the  $\text{Co}^{2+}$  complex of the *N*-(2,2,2-trifluoroethyl) cyclam derivative.<sup>45</sup>

In the  $^{19}\text{F}$  NMR spectrum of  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$ , one broad signal centred at  $-50.5$  ppm is present (Fig. S15 $\dagger$ ) which shows optimally fast longitudinal relaxation in order tens of milliseconds ( $T_1$  40–80 ms, dependent on the external magnetic field strength and temperature, Table 5), although its transversal relaxation is very fast (Table 6). This compound also shows a broad  $^{31}\text{P}\{^1\text{H}\}$  NMR signal at *ca.* 200 ppm (Fig. S16 $\dagger$ ). When the  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex is oxidized with  $\text{K}_2\text{S}_2\text{O}_8$  or  $\text{H}_2\text{O}_2$ , a set of multiplets (pseudo-quartets due to similar values of  $J_{\text{FH}}$  and  $J_{\text{FP}}$ ) of  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  gradually appears in the  $^{19}\text{F}$  NMR spectrum (Fig. 13). It is consistent with the data from spectro-electrochemical experiments (Fig. S33 $\dagger$ ). The signals are narrow and their relaxation is slow. Thus, the formed  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  complex is obviously diamagnetic with a low-spin  $d^6$  arrangement. Several close and hardly separable  $^{19}\text{F}$  NMR signals of  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  appear which can be explained by the presence of isomers with different *R/S* configurations on the phosphinate groups. These isomers are not exchanged due to kinetic inertness and non-fluxionality of the  $\text{Co}^{3+}$  complexes, and each affords individual signal(s).

The  $^{19}\text{F}$  NMR spectrum of the  $[\text{Ni}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex contains two broad  $^{19}\text{F}$  NMR signals separated by *ca.* 3 ppm, with

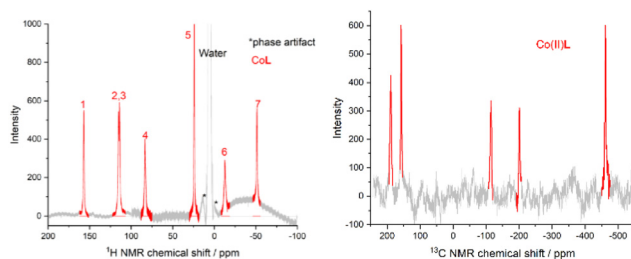

Fig. 12  $^1\text{H}$  (left) and  $^{13}\text{C}\{^1\text{H}\}$  (right) NMR spectra of the  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex ( $\text{D}_2\text{O}$ ,  $\text{pD}$  7.4,  $37^\circ\text{C}$ ).

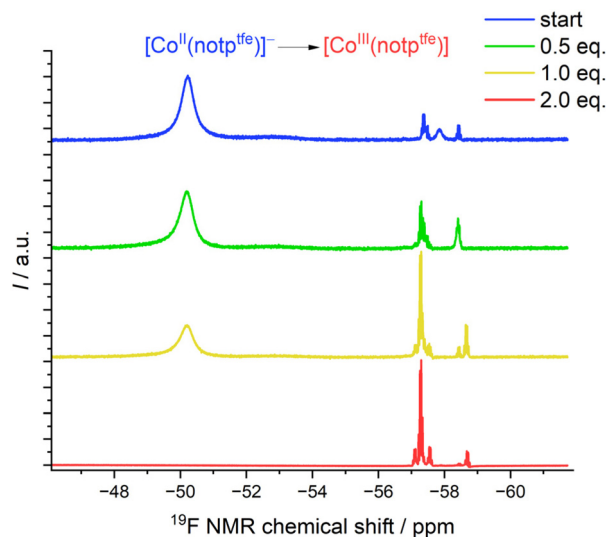

Fig. 13  $^{19}\text{F}$  NMR spectra of the reaction mixtures showing gradual oxidation of  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  to  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]$  with  $\text{K}_2\text{S}_2\text{O}_8$ .

a relative intensity *ca.* 10:90% (Fig. S18 $\dagger$ ). In the case of  $[\text{Cu}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$ , only one broad signal was observed (Fig. S20 $\dagger$ ). The signals of both complexes relax very fast with  $T_1$  in the range of *ca.* 3–5 ms and  $T_2$  *ca.* 2 ms (Tables 5 and 6).

Overall, the observed relaxation times are consistent with those found previously for the complexes of the related cyclam-based ligand 1,8- $\text{H}_2\text{te}2\text{p}^{\text{tfe}}$  (Fig. 1) with the same pendant arm.<sup>47</sup> Fast movement of the 2,2,2-trifluoroethyl group effectively averages the distances; however, the mean value cannot be reliably calculated as it strongly correlates with electronic relaxation times whose exact values are not known and, for individual metal ions, can cover a wide range.<sup>47</sup> However, the  $[\text{Cr}^{\text{III}}(\text{notp}^{\text{tfe}})]$ ,  $[\text{Mn}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  and  $[\text{Fe}^{\text{III}}(\text{notp}^{\text{tfe}})]$  complexes cannot be utilised in  $^{19}\text{F}$  MRI as they show very broad signals which relax too fast and, therefore, are not reliably detectable. The relaxation characteristics of the  $[\text{Ni}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  and  $[\text{Cu}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complexes are more suitable but their potential use in the imaging experiments would need special ultrafast measurement techniques<sup>90,91</sup> due to too short relaxation times (few milliseconds). In this respect, the most promising is the  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  complex showing optimally fast longitudinal relaxation ( $T_1$  in order of tens of milliseconds) which is suitable for standard MRI hardware. Furthermore, the redox potential of the  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]/[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  pair has physiologically relevant value making the compound potentially employable as a redox probe.

## Conclusions

A new 1,4,7-triazacyclononane-based ligand substituted with three (2,2,2-trifluoroethyl)phosphinate pendant arms was studied with respect to its potential use in contrast agents for  $^{19}\text{F}$  Magnetic Resonance Imaging ( $^{19}\text{F}$  MRI). With a large metal ion  $\text{Mn}^{2+}$ , the ligand forms complexes with twisted-trigonal-

antiprismatic geometry, whereas with the smaller ions  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$  and  $\text{Zn}^{2+}$ , complex species with an octahedral geometry are formed. With the  $\text{Co}^{2+}$  ion, both environments were observed. Complexes of  $\text{Co}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$  and  $\text{Zn}^{2+}$  are very stable and are fully formed at  $\text{pH} > \sim 3$ . Paramagnetic metal ion complexes show very short relaxation times of the  $^{19}\text{F}$  NMR signal due to a short distance between the paramagnetic metal ion and the fluorine atoms (values found in the crystal structures are  $\sim 5.5$ – $6.5$  Å). Most of the studied complexes show too fast longitudinal relaxation for the application ( $T_1$  of the  $\text{Cr}^{3+}$ ,  $\text{Mn}^{2+}$  and  $\text{Fe}^{3+}$  complexes in the sub-millisecond range; the  $\text{Ni}^{2+}$  and  $\text{Cu}^{2+}$  complexes  $\sim 4$  ms), but  $T_1$  of  $[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  (40–80 ms) falls in a range suitable for easy exploitation. Electrochemical studies revealed the formation of a stable diamagnetic  $\text{Co}^{3+}$  complex ( $E_{1/2}$  0.95 V vs. SCE). Together with a suitable relaxation time, it makes the  $[\text{Co}^{\text{III}}(\text{notp}^{\text{tfe}})]/[\text{Co}^{\text{II}}(\text{notp}^{\text{tfe}})]^-$  pair potentially useful as a smart redox-responsive contrast agent in  $^{19}\text{F}$  MRI.
