rsc.li/dalton

We describe a study of the influence of cryptand denticity on the structural, electronic, and electrochemical properties of U<sup>III</sup>-containing cryptates. Two cryptands (2.2.2 and 2.2.1) are reported. The cryptand with the smaller denticity leads to negative electrochemical potentials and shorter bond lengths that are consistent with a better fit for U<sup>III</sup> than the larger cryptand. These studies provide insight into the rational design of cryptand-based ligands for trivalent uranium.

## Introduction

The accumulation of depleted uranium as a waste product from uranium enrichment encourages the development of research focused on uranium coordination chemistry.<sup>1–3</sup> Reported studies in this area provide insight into potential uses of depleted uranium and fundamental knowledge of uranium coordination chemistry involved in applications such as actinide separations in nuclear waste.<sup>4–8</sup> Within this context, there have been widespread reports of redox-active and redox-inactive ligands used to form complexes of U<sup>III</sup>,<sup>9–16</sup> and one of those ligands, 2.2.2-cryptand, has been widely used to encapsulate metal ions, including U<sup>III</sup>.<sup>17–19</sup> Further, the coordination chemistry of U<sup>III</sup>, Np<sup>III</sup>, and Pu<sup>III</sup> with 2.2.2-cryptand has been reported recently,<sup>20</sup> expanding cryptand chemistry into the actinides. The thermodynamic and kinetic stability of a cryptate is governed by the cavity size and denticity of the coordinated cryptand as well as the ionic radii and oxidation state of the given metal ion.<sup>21–24</sup> For example, 2.2.1-cryptand fits better with Eu<sup>III</sup>, and 2.2.2-cryptand fits better with Eu<sup>II</sup>; moreover, the Gibbs free energy of Eu<sup>III</sup>(2.2.1-cryptand) is 1.8 times greater than that of Eu<sup>III</sup>(2.2.2-cryptand), and the dissociation constant of Eu<sup>III</sup>(2.2.1-cryptand) is 2.7 × 10<sup>3</sup> times smaller than that of Eu<sup>III</sup>(2.2.2-cryptand).<sup>24</sup> Because the size of U<sup>III</sup> (1.025 Å) is closer to the size of Eu<sup>III</sup> (0.947 Å)

than Eu<sup>II</sup> (1.17 Å)<sup>25</sup> and the charge density of U<sup>III</sup> is closer to Eu<sup>III</sup> than Eu<sup>II</sup>, we suspected that 2.2.1-cryptand would be a good ligand for U<sup>III</sup>. Additional support for this suspicion is in our recent report that the flexible counterpart of 2.2.2-cryptand, tris[2-(2-methoxyethoxy)ethyl]amine (TDA-1), forms U<sup>III</sup>-containing complexes with smaller coordination numbers (nine) compared to all reported 2.2.2-cryptates (with coordination numbers of ten).<sup>26</sup> This report of an acyclic ligand implies that trivalent uranium can be encapsulated by cryptands with smaller denticities than that of 2.2.2-cryptand. Therefore, based on the studies of Eu<sup>III</sup> cryptand chemistry and U<sup>III</sup> chemistry with acyclic TDA-1, we hypothesized that 2.2.1-cryptand is a better match for U<sup>III</sup> than 2.2.2-cryptand. Here, we report U<sup>III</sup>-containing cryptates of 2.2.2- and 2.2.1-cryptand (Fig. 1) to investigate how ligand denticity affects the structural, spectroscopic, and electrochemical properties of U<sup>III</sup>.

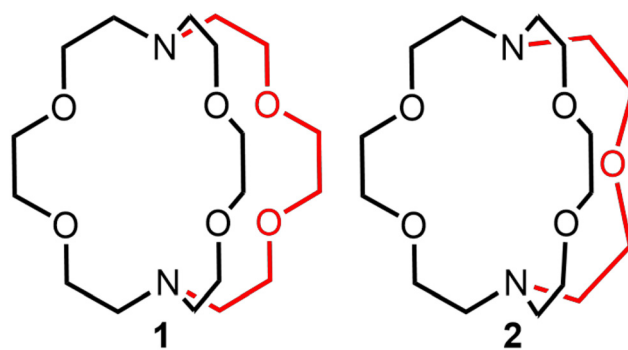

Fig. 1 2.2.2-Cryptand, 1, and 2.2.1-cryptand, 2, that were studied with U<sup>III</sup>. The red color highlights the difference between the two ligands.

## Results and discussion

To evaluate the structural properties of U<sup>III</sup>-containing cryptates, crystals were grown from *N,N*-dimethylformamide (DMF) or acetonitrile (CH<sub>3</sub>CN) (Schemes 1 and 2), and the structures of [U<sup>III</sup>1(DMF)<sub>2</sub>]<sub>3</sub>, [U<sup>III</sup>2(CH<sub>3</sub>CN)<sub>2</sub>]<sub>3</sub>, and [U<sup>III</sup>2(DMF)<sub>2</sub>]<sub>3</sub> were solved from the crystals (Fig. 2). All three complexes contained coordinated solvent molecules. The structure with **1** is like reported structures of 2.2.2-cryptates of trivalent uranium that share ten-coordinate structures with bound solvent molecules, iodide,<sup>18,20</sup> triflate,<sup>22</sup> or water molecules.<sup>18,20</sup> The geometry of [U<sup>III</sup>1(DMF)<sub>2</sub>]<sub>3</sub>, analyzed by SHAPE (v.2.1),<sup>27</sup> is sphenocorona. We also performed SHAPE analysis for the reported structure of [U<sup>III</sup>1(CH<sub>3</sub>CN)]<sub>2</sub> with one inner-sphere iodide and one inner-sphere molecule of CH<sub>3</sub>CN (CCDC number 2020050),<sup>19</sup> and we found that it also has the sphenocorona geometry. The crystal structure that we report here contains two coordinated molecules of DMF instead of iodide, water, or triflate, but the change in monodentate donors does not change the geometry about U<sup>III</sup>. In contrast to [U<sup>III</sup>1(DMF)<sub>2</sub>]<sub>3</sub>, U<sup>III</sup> with **2** adopts a nine-coordinate structure with two molecules of CH<sub>3</sub>CN {[U<sup>III</sup>2(CH<sub>3</sub>CN)<sub>2</sub>]<sub>3</sub>} or two molecules of DMF {[U<sup>III</sup>2(DMF)<sub>2</sub>]<sub>3</sub>} coordinated to the opposite face of uranium relative to the single-oxygen-bearing arm of **2**. Both [U<sup>III</sup>2(CH<sub>3</sub>CN)<sub>2</sub>]<sub>3</sub> and [U<sup>III</sup>2(DMF)<sub>2</sub>]<sub>3</sub> possess spherical-relaxed capped cube geometries as determined by SHAPE (v.2.1). U<sup>III</sup>-containing complexes of **1** and **2** exhibit poor solubility in ethereal and nonpolar solvents, and for this reason, DMF and CH<sub>3</sub>CN were used for crystallization. Comparison of bond lengths between [U<sup>III</sup>2(CH<sub>3</sub>CN)<sub>2</sub>]<sub>3</sub> and [U<sup>III</sup>2(DMF)<sub>2</sub>]<sub>3</sub> reveals no noticeable variation in bond lengths between uranium and the donor atoms in **2**; however, the U–O<sub>DMF</sub> bond in the complex with coordinated DMF is shorter than the U–N<sub>CH<sub>3</sub>CN</sub> bond in the complex with coordinated CH<sub>3</sub>CN, as expected based on the difference in size between O and N (Table 1). Similarly, U–O<sub>ether</sub> bonds in [U<sup>III</sup>2(CH<sub>3</sub>CN)<sub>2</sub>]<sub>3</sub>, [U<sup>III</sup>2(DMF)<sub>2</sub>]<sub>3</sub>, and [U<sup>III</sup>1(DMF)<sub>2</sub>]<sub>3</sub> are shorter than U–N<sub>amine</sub> bonds. The complexes [U<sup>III</sup>2(CH<sub>3</sub>CN)<sub>2</sub>]<sub>3</sub> and [U<sup>III</sup>2(DMF)<sub>2</sub>]<sub>3</sub> each contain U–O<sub>ether</sub> and U–N<sub>amine</sub> bonds that are 0.1–0.2 Å shorter than similar bonds in [U<sup>III</sup>1(DMF)<sub>2</sub>]<sub>3</sub>. However, U–O<sub>DMF</sub> bond lengths in [U<sup>III</sup>1(DMF)<sub>2</sub>]<sub>3</sub> and [U<sup>III</sup>2(DMF)<sub>2</sub>]<sub>3</sub> do not exhibit large differences relative to each

[U <sup>III</sup> 2(DMF) <sub>2</sub> ] <sub>3</sub>	2.547(3)	2.683(3)	NA	2.471(3)
[U <sup>III</sup> 2(CH <sub>3</sub> CN) <sub>2</sub> ] <sub>3</sub>	2.507(3)	2.661(3)	NA	2.644(4)
[U <sup>III</sup> 1(I)(CH <sub>3</sub> CN) <sub>2</sub> ] <sub>3</sub> <sup>19</sup>	2.640(2)	2.818(3)	3.2594(7)	2.647(3)
[U <sup>III</sup> (TDA-1)(I) <sub>2</sub> ] <sub>3</sub> <sup>26</sup>	2.605(6)	2.767(7)	3.2045(7)	NA

NA = not applicable.

other. The U–O<sub>ether</sub> and U–N<sub>amine</sub> bonds in [U<sup>III</sup>2(CH<sub>3</sub>CN)<sub>2</sub>]<sub>3</sub> and [U<sup>III</sup>2(DMF)<sub>2</sub>]<sub>3</sub> are shorter than analogous bonds in reported U<sup>III</sup>-containing complexes with TDA-1.<sup>26</sup>

In addition to solid-state characterization, electronic spectroscopic characterization was performed for U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub> to analyze how ligand denticity influences solution properties of the complexes. We performed UV-visible and near-IR experiments using elementally pure U<sup>III</sup>-containing complexes of **1** and **2** that does not include coordinated solvent molecules. Those complexes are referred to as U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub>. UV-visible and near-IR electronic absorption data were collected from 350 to 1400 nm in CH<sub>3</sub>CN (Fig. 3). In the visible region, color-producing bands in U<sup>III</sup>1<sub>3</sub> appeared for the green-yellow solutions in acetonitrile with maximum absorbances at 395 nm ( $\epsilon = 978 \text{ M}^{-1} \text{ cm}^{-1}$ ). U<sup>III</sup>2<sub>3</sub> forms reddish-pink solutions in CH<sub>3</sub>CN with color-producing bands having maxima at 407 nm ( $\epsilon = 1008 \text{ M}^{-1} \text{ cm}^{-1}$ ) with shoulders at 521 nm ( $\epsilon = 603 \text{ M}^{-1} \text{ cm}^{-1}$ ). Weak bands appear in the near-IR region for U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub> like the other complexes of trivalent uranium with 5f<sup>3</sup> electronic configurations with Laporte-forbidden f–f transitions.<sup>18,28,29</sup> These bands in near IR-region are broader than the U<sup>III</sup>1<sub>3</sub> bands in acetonitrile (Fig. S3†) and the reported acyclic U<sup>III</sup>TDA-1.<sup>26</sup> The differences in the optical properties of U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub> in solution, specifically the large differences in shifts of color producing bands, indicate an influence of the change of ligand

**Fig. 3** Electronic absorption spectra for U<sup>III</sup>1<sub>3</sub> (···) and U<sup>III</sup>2<sub>3</sub> (—) in CH<sub>3</sub>CN.**Fig. 4** Cyclic voltammograms of (A) [U<sup>III</sup>1]<sub>3</sub> (3.36 mM) and (B) [U<sup>III</sup>2]<sub>3</sub> (3.42 mM) in CH<sub>3</sub>CN (scan rate = 100 mV s<sup>-1</sup>).

denticity from octadentate to heptadentate on 5f–6d orbital energy gaps.

To study the electrochemical behavior of U<sup>III</sup>-containing cryptates, cyclic voltammetry was performed for U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub> in CH<sub>3</sub>CN (Fig. 4). Oxidation peaks corresponding to the U<sup>III/IV</sup> couple appear at  $-0.26 \text{ V}$  versus ferrocene/ferrocenium (Fc/Fc<sup>+</sup>) for U<sup>III</sup>1<sub>3</sub>. The oxidation potential of the U<sup>III/IV</sup> couple of U<sup>III</sup>1<sub>3</sub> in CH<sub>3</sub>CN is like the reported oxidation potential ( $-0.31 \text{ V}$  versus Fc/Fc<sup>+</sup>) of U<sup>III</sup>2.2.2-cryptate.<sup>19</sup> The cyclic voltammogram of U<sup>III</sup>2<sub>3</sub> contains an oxidation peak corresponding to the U<sup>III/IV</sup> couple at  $-0.46 \text{ V}$  versus Fc/Fc<sup>+</sup>. Both U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub> contain an oxidation peak corresponding to a U<sup>III</sup>-to-U<sup>IV</sup> oxidation that is not observed in the voltammogram of U<sup>III</sup>1<sub>3</sub> (Fig. S2†). Cyclic voltammograms of U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub> were performed using elementally pure powdered compounds that do not contain coordinated solvent molecules. Both U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub> can coordinate at least one acetonitrile molecules in that solid state as evidenced by reported crystal structures<sup>19</sup> and this study. Similarly, in solution, acetonitrile can coordinate to U<sup>III</sup>1<sub>3</sub>, U<sup>III</sup>2<sub>3</sub>, and U<sup>III</sup>1<sub>3</sub>. However, cyclic voltammetry of U<sup>III</sup>1<sub>3</sub>, U<sup>III</sup>2<sub>3</sub>, and U<sup>III</sup>1<sub>3</sub> in this study were performed in the same solvent, acetonitrile; consequently, the variability in shifts of oxidation potentials that arises from the coordination of solvent is minimized. Therefore, the observed 0.2 V difference in oxidation potentials between U<sup>III</sup>1<sub>3</sub> and U<sup>III</sup>2<sub>3</sub> in acetonitrile most likely arises from changes in the ionization energies resulting from changes in the ligand structure. These results indicate that oxidation potentials of U<sup>III</sup>2<sub>3</sub> shift to more negative potentials with the decrease of coordination number compared to the octadentate cryptand in U<sup>III</sup>1<sub>3</sub>. The negative shift in oxidation potential is likely due to the smaller denticity of **2** compared to **1** and consequent size match between U<sup>III</sup> and **2**. A similar relationship is observed in the reported study between Eu<sup>III</sup>-containing complexes of **1** and **2**.<sup>30</sup> The formal potential of Eu<sup>III</sup>2 ( $-425 \text{ mV}$  versus saturated calomel electrode) is more negative than that of Eu<sup>III</sup>1 ( $-225 \text{ mV}$  versus saturated calomel elec-

trode). Therefore, the negative shift in cyclic voltammetry of  $U_2I_3$  is consistent with the electrochemistry of 4f systems. Interestingly,  $U_1I_3$  and  $U_2I_3$  have electrochemical potentials among the most positive of reported  $U^{III/IV}$  couples of monometallic complexes of uranium.<sup>31</sup> The reported  $U^{III}$  complexes that coordinated to negatively charged donor atoms increase the electron density of uranium and consequently result in more negative electrochemical potentials.<sup>31</sup> Therefore, the observed positive shift in electrochemical potential is not surprising for  $U^{III}$ -containing cryptates of **1** and **2** when compared to complexes of cyclopentadienyls, bis(trimethylsilyl)amides, tris(aryloxides), and  $\beta$ -diketiminates.<sup>31</sup> However, to the best of our knowledge, the relationship of cryptand denticity on electrochemical studies of actinide series has not been reported; therefore, the insight gained from the electrochemical studies described here provides information regarding the influence of cryptand denticity on the tuning of the electrochemical potential of  $U^{III}$ .

## Experimental

### General methods

All air- and moisture-sensitive reactions were performed using standard Schlenk technique with Ar or using an inert atmosphere dry glove box under an atmosphere of  $N_2$ . Commercially available anhydrous solvents were used for air- and moisture-sensitive reactions after degassing under reduced pressure and drying over activated molecular sieves ( $CH_3CN$  with 3 Å sieves, diethyl ether and DMF with 4 Å sieves, and tetrahydrofuran and 1,4-dioxane with 5 Å sieves).

Depleted uranium was purchased from Manufacturing Science Cooperation (Oak Ridge, TN) and purified following a reported procedure.<sup>32</sup>  $U_3(1,4\text{-dioxane})_{1.5}$  was synthesized following a reported procedure.<sup>32</sup> 4,7,13,16,21,24-Hexaoxa-1,10-diazabicyclo[8.8.8]hexacosane (**1**) and 4,7,13,16,21-pentaoxa-1,10-diazabicyclo[8.8.5]tricosane (**2**) were purchased from commercial sources.

Elemental analyses were performed by the Microanalytical Facility at the University of California, Berkeley. Electronic absorption spectra were collected using a Jasco UV-Vis-NIR spectrophotometer, and metal concentrations were determined using energy-dispersive X-ray fluorescence spectroscopy with a Shimadzu EDX-7000 spectrometer at the Lumigen Instrument Center in the Department of Chemistry at Wayne State University.

Cyclic voltammetry was performed using a three-electrode setup with a Pine Wavenow USB potentiostat under an atmosphere of Ar with a glassy carbon working electrode, a freshly prepared Ag/AgCl wire pseudo reference electrode (Ag wire with AgCl coating was prepared by dipping a polished Ag wire in bleach for 5–10 min), and a Pt-wire auxiliary electrode. Acquisition parameters of  $[U^{III}1]I_3$  and  $[U^{III}2]I_3$  were eight segments, an initial potential of  $-0.5$  or  $0.0$  V (rising), an upper potential of  $0.7$  V, a lower potential of  $-0.5$  V or  $0.0$  V against Ag/AgCl pseudo reference electrode, and a scan rate of  $100$  mV

$s^{-1}$ . Tetrabutylammonium trifluoromethanesulfonate ( $0.1$  M) was used as the electrolyte, and analyte concentrations were  $3.0$ – $3.5$  mM. All cyclic voltammograms were recorded in  $CH_3CN$  referenced to an internal standard of  $Fc/Fc^+$ .

A crystal of  $[U^{III}1(DMF)_2]I_3$  was mounted on a Bruker X8 APEX-II diffractometer with Mo radiation and a graphite monochromator. The X-ray diffraction intensities were measured using a Bruker APEX-II charge-couple device detector. Crystals of  $[U^{III}2(DMF)_2]I_3$  and  $[U^{III}2(CH_3CN)_2]I_3$  were mounted on a Bruker D8 Venture diffractometer with kappa geometry, an Incoatec  $I\mu S$  micro-focus source X-ray tube (Mo  $K\alpha$  radiation), and a multilayer mirror for monochromatization. The X-ray diffraction intensities were measured using a Photon III CPAD area detector. Data for  $[U^{III}1(DMF)_2]I_3$ ,  $[U^{III}2(DMF)_2]I_3$ , and  $[U^{III}2(CH_3CN)_2]I_3$  were acquired at  $100$  K with an Oxford 800 Cryostream low-temperature apparatus. The intensities were integrated using SAINT V8.38a software. A multiscan absorption correction was applied with SADABS v2016/2 using APEX4 v2021.10-0. Crystal structures were solved using a dual-space approach as implemented in SHELXT program<sup>33</sup> and difference Fourier maps during least-squares refinement, as embedded in SHELXL-2018<sup>34</sup> running under Olex2.<sup>35</sup>

### Synthesis of $U^{III}$ -containing cryptates

**$U^{III}1I_3$  (Scheme 1).** A solution of  $U_3(1,4\text{-dioxane})_{1.5}$  ( $193.7$  mg,  $0.2580$  mmol) in tetrahydrofuran ( $2$  mL) was added to a solution of **1** ( $97.1$  mg,  $0.258$  mmol) in tetrahydrofuran ( $2$  mL). The resulting dark-brown mixture was stirred for  $1$  h. The precipitate was collected by filtration and washed with tetrahydrofuran ( $4 \times 4$  mL). Residual solvent was removed under reduced pressure to obtain  $U^{III}1I_3$  as a dark-brown powder ( $139.1$  mg,  $56\%$  yield). Anal. calcd for  $UC_{18}H_{36}I_3N_2O_6$ : C,  $21.72$ ; H,  $3.65$ ; N,  $2.81$ . Found (%): C,  $21.88$ ; H,  $3.45$ ; N,  $2.63$ . To prepare crystals,  $U^{III}1I_3$  powder ( $\sim 20$  mg) was dissolved in DMF ( $\sim 1$  mL). Vapor diffusion of diethyl ether into the DMF solution at  $4$  °C yielded green, X-ray quality crystals of  $[U^{III}1(DMF)_2]I_3$ .

**$U^{III}2I_3$  (Scheme 2).** A solution of  $U_3(1,4\text{-dioxane})_{1.5}$  ( $225.3$  mg,  $0.3000$  mmol) in tetrahydrofuran ( $2$  mL) was added to a solution of **2** ( $100.0$  mg,  $0.3000$  mmol) in tetrahydrofuran ( $2$  mL). A red precipitate formed, and the reaction mixture was stirred for  $1$  h. The precipitate was collected by filtration and washed with tetrahydrofuran ( $4 \times 4$  mL). Residual solvent was removed under reduced pressure to obtain  $U^{III}2I_3$  as a pink-red powder ( $70.3$  mg,  $51\%$  yield). Anal. calcd for  $UC_{16}H_{32}I_3N_2O_5$ : C,  $20.20$ ; H,  $3.39$ ; N,  $2.95$ . Found (%): C,  $19.68$ ; H,  $3.01$ ; N,  $2.69$ . Red crystals of  $[U^{III}2(DMF)_2]I_3$  were formed at ambient temperature by vapor diffusion of diethyl ether into a solution of  $U^{III}2I_3$  ( $\sim 20$  mg) in DMF ( $\sim 1$  mL). Red crystals of  $[U^{III}2(CH_3CN)_2]I_3$  were formed by vapor diffusion of diethyl ether/hexanes ( $1 : 1$ ) into a solution of  $U^{III}2I_3$  ( $\sim 20$  mg) in  $CH_3CN$  ( $\sim 1.5$  mL).

## Conclusions

This study reports differences in the structural, spectroscopic, and electrochemical properties of  $U^{III}$  encapsulated into

neutral, redox-inactive cryptands. The smaller denticity and cavity size of heptadentate **2** enabled greater bonding interactions with U<sup>III</sup> compared to octadentate **1**. This evidence of a favorable size match between 2.2.1-cryptand and U<sup>III</sup> is supported by shorter bond lengths and negative shifts of the electrochemical potentials of U<sup>III</sup>**2** compared to U<sup>III</sup>**1**. These findings provide valuable insight into the encapsulation of trivalent uranium that has potential use areas such as actinide separations relevant to the management of radioactive waste.

## Conflicts of interest

There are no conflicts to declare.

## Acknowledgements

We acknowledge the ACS-PRF (59577-ND3) for funding. NMR spectroscopy and X-ray crystallography were performed in the Lumigen Instrument Center at Wayne State University that is partially supported by the National Institutes of Health (3R01EB027103-02S1 and S10OD028488). We thank Professor Long Luo for helpful discussions.
