

# Sustainable Food Technology

Accepted Manuscript

This article can be cited before page numbers have been issued, to do this please use: L. Sarma, F. Patra, P. Kumar Borah, S. Meena and R. K. Duary, *Sustainable Food Technol.*, 2024, DOI: 10.1039/D4FB00382A.

This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

## Sustainability spotlight

*Coptis teeta* is a medicinal plant highly valued for its bioactive phytochemicals but also recognized for ecological sensitivity due to overharvesting. This study promotes the sustainable use of *Coptis teeta* rhizomes by employing microwave and ultrasound assisted extraction— green techniques that maximize high-value bioactive yield while minimizing resource consumption. By providing standardized methods and solvent compositions, this research reduces the environmental impact of conventional methods and helps alleviate harvesting pressure on wild plant populations, thereby supporting green industrial practices and the circular bioeconomy.

## 20 Abstract

21 *Coptis teeta* rhizomes are a rich source of bioactive phytochemicals with significant applications  
22 in the food and nutraceutical industries. Standardized methods and solvent compositions are crucial  
23 for maximizing bioactive yield while ensuring industrial feasibility. This study models and  
24 compares microwave (MAE) and ultrasound (UAE) assisted extraction of phenolics and berberine—  
25 the primary active alkaloid in *Coptis teeta* rhizome, to define standardized solvent concentration  
26 for industrial applicability. Previous studies on extracting phytochemicals from *Coptis teeta* have  
27 relied on the central composite design, which is limited in handling multiple independent variables.  
28 To address this, a Box–Behnken design along with a response surface method was utilized, where  
29 independent variables included solvent concentration (water: methanol), power level, extraction  
30 time, and solid-liquid ratio, and dependent variables were total phenolic content (TPC) and  
31 antioxidant activity. Results showed that for MAE, using 65% solvent concentration, 310 W power,  
32 30 min extraction time, and 1:39 g mL<sup>-1</sup> solid-liquid ratio resulted in TPC of 210.04 mg GAE 100g<sup>-</sup>  
33 <sup>1</sup> and antioxidant activity of 98.57%. Whereas for UAE, 36% solvent concentration, 160 W  
34 ultrasound power, 10 min extraction time, and 1:78 g mL<sup>-1</sup> solid-liquid ratio resulted in TPC of  
35 251.11 mg GAE 100g<sup>-1</sup> and 97.82% antioxidant activity. Berberine concentration in MAE extract  
36 was 212.18 ppm, whereas 162.96 ppm in UAE extract. While MAE yielded a higher berberine  
37 yield, UAE was superior in extracting total phenolics. The results could provide a foundation for  
38 developing standardized methods and solvent compositions for food and nutraceutical  
39 formulations.

40 **Keywords:** Berberine; *Coptis teeta*; HPLC; microwave assisted extraction; modeling; ultrasound  
41 assisted extraction

## 42 Sustainability spotlight

43 *Coptis teeta* is a medicinal plant highly valued for its bioactive phytochemicals but also recognized  
44 for ecological sensitivity due to overharvesting. This study promotes the sustainable use of *Coptis*  
45 *teeta* rhizomes by employing microwave and ultrasound assisted extraction– green techniques that  
46 maximize high-value bioactive yield while minimizing resource consumption. By providing  
47 standardized methods and solvent compositions, this research reduces the environmental impact of  
48 conventional methods and helps alleviate harvesting pressure on wild plant populations, thereby  
49 supporting green industrial practices and the circular bioeconomy.

## 50 1. Introduction

51 Plants are abundant in bioactive phytochemicals and have garnered significant research and  
52 industrial attention due to their extensive health benefits and industrial applicability (1-3). In this  
53 regard, *Coptis teeta* is a major pharmacological plant species widely utilized in Indian and Chinese  
54 traditional medicine (4, 5). The plant is a perennial herb from the Ranunculaceae family and is  
55 predominantly found in the forested regions of Sikkim and Arunachal Pradesh in India, Bhutan,  
56 and Yunnan in China. There are 15 identified species in the genus, all native to Asia (4). The  
57 efficacy of this plant and its dried rhizome has been documented to show various  
58 pharmacologically beneficial effects in fever, gastrointestinal disorders, malaria, detoxification,  
59 and other antibacterial, antiviral, anti-inflammatory, and anti-hyperglycemic activities (6-12). In  
60 this regard, *Coptis teeta* Wall. is an endemic and endangered medicinal plant found in the Mishmi  
61 Hills of Arunachal Pradesh in India (4, 5, 13). Locally the plant is referred as ‘*Mishmi tita*’ (4). The  
62 bitter taste of the rhizome is associated with the word ‘teeta/tita’ (4). The indigenous people of  
63 Arunachal Pradesh have traditionally used its dried rhizome to treat various ailments such as  
64 gastrointestinal disorders, malaria, and detoxification (4, 14). *Coptis teeta* is a rich source of  
65 phytochemicals, and studies have revealed phytochemicals such as berberine, palmatine,  
66 jatrorrhizine, coptisine, columbamine, and epiberberine as the predominant phenolic constituents  
67 (4, 6, 15). Among these, the major phytochemical in *Coptis teeta* is berberine, which occurs in high  
68 concentrations in the *Coptis teeta* rhizomes (4). Berberine, often called the wonder molecule, is a  
69 benzyloquinoline plant alkaloid (16). Berberine demonstrates broad-spectrum pharmacological  
70 properties and recent research has highlighted its potential therapeutic applications, including  
71 anticancer, anti-diabetic, anti-inflammatory properties, and effects on the central nervous system  
72 and cardiovascular system (11, 16, 17). Given these considerations, it becomes crucial to explore

73 efficient and green extraction methods to prevent overexploitation while enabling the responsible  
74 utilization of its valuable phytochemicals for industrial use.

75 A crucial step in extracting phytochemicals is optimizing the extraction of compounds to  
76 promote greater extraction efficiencies. Green technologies primarily include industrially viable  
77 methods such as microwave-assisted extraction (MAE) (18) and ultrasound-assisted extraction  
78 (UAE) (19). MAE is commonly used in the food, pharmaceutical, and cosmetics industries. MAE  
79 involves the application of electromagnetic waves that penetrate plant cellular matrices and interact  
80 with polar groups, causing dipole heating primarily *via* polarization of water molecules. This  
81 generates significant heat and pressure, causing cellular membrane disassembly and release of  
82 cellular constituents into the surrounding liquid medium (20, 21). Conversely, UAE is commonly  
83 used in the chemical and food industries. UAE utilizes cavitation effects to rupture plant cell walls,  
84 enhancing the interaction between solid-liquid phases and contributing to mass diffusivity (22, 23).  
85 Recent studies in MAE and UAE methods have shown that the efficiency of phytochemical  
86 extraction depends on factors such as solvent concentration, microwave/ultrasound power,  
87 extraction time, and solid-liquid ratio (24, 25). The optimization of these extraction techniques  
88 would thereby ensure maximal phytochemical yield while minimizing solvent and material use,  
89 energy consumption, and extraction time (26). The effectiveness of MAE and UAE has been  
90 demonstrated for extracting phytochemicals from *Coptis chinensis* Franch.– predominantly found  
91 in China (27, 28) and in other plant materials such as olive leaves (29), sesame leaves (30), passion  
92 fruit peel (31), and grape pomace (22).

93 However, reports on the green extraction of phytochemicals from *Coptis teeta* Wall. is  
94 lacking in current literature to our knowledge. As discussed earlier, only two reports have  
95 demonstrated that MAE and UAE could improve the extraction of phytochemicals from the closely

96 related genus, but distinct species *Coptis chinensis* Franch. (27, 28). However, both past studies  
97 used a central composite design, which is limited in its capacity to model more than three  
98 independent variables. This study builds and expands on the previous studies to utilize MAE and  
99 UAE techniques to extract phenolics from *Coptis teeta* Wall. rhizomes. Furthermore, a Box–  
100 Behnken experimental design is employed with the response surface method, a mathematical  
101 modeling and optimization routine frequently applied to improve the extraction of phytochemicals  
102 from natural sources. This approach offers advantages over the central composite design, including  
103 suitability for more than three factors, elimination of extreme factor levels, greater uniform  
104 precision, spherical design space, and lower risk of aliasing. It is hypothesized that this enhanced  
105 modeling routine will improve phenolic extraction from *Coptis teeta* Wall. rhizomes and responds  
106 to the ecological imperative of reducing overexploitation, while supporting industrial translation.  
107 The findings offer standardised methods and solvent concentrations for preparing *Coptis teeta*  
108 Wall. extracts in food and nutraceutical industries.

## 109 2. Materials and Methods

110 **2.1. Materials.** Fresh rhizomes of *Coptis teeta* Wall. plants were collected from Arunachal Pradesh  
111 in India. Samples were washed thoroughly and dried in hot air oven at 40°C for 72 h. The dried  
112 rhizomes were grounded to a powder, sieved using mesh 60, and then stored in airtight low-density  
113 polyethylene pouches for future use. The plant herbarium specimen was also deposited at the  
114 Assam Agricultural University, India (voucher specimen number 5296).

115 All chemicals used in the study were procured from HiMedia, India. All solvents utilized  
116 in the study were from Merck, India and of analytical grade. HPLC standards were purchased from  
117 Sigma, India.

118 **2.2. Microwave (MAE) and ultrasound (UAE) assisted extraction.** One gram of the dried  
119 rhizome powder was used for microwave-assisted extraction according to the Box–Behnken  
120 experimental design (Table 1) using a variable power and irradiation time microwave oven (Model:  
121 MJ3283BCG, LG Electronics, India). Intermittent cyclic heating of 30s was utilized to prevent  
122 solvent overheating. The independent variables were power level (180 – 900 W), extraction time  
123 (1 – 30 min), solid-liquid ratio (1:10 - 40 g mL<sup>-1</sup>), and methanol concentration (50 - 70%). After  
124 treatment, extracts were centrifuged at 3500 rpm for 10 min and filtered through a Whatman Filter  
125 paper No. #1, and stored in the dark at 4°C for further analysis. Coded variables are shown in  
126 Figure S1.

127 The extractions of bioactive molecules were carried out in a variable ultrasonic power and  
128 ultrasound time UW 2070 ultrasonic instrument (Bandelin Sonoplus, Germany) with a frequency  
129 of 25 kHz using a titanium alloy probe (diameter, 1.5 cm). An intermittent cycle duration of 10  
130 seconds was utilized. The entire setup was maintained in an ice bath so the temperature would not

131 rise above 20°C. The powdered samples were treated with various combinations of independent  
132 variables, *viz.*, solvent concentration (0 - 100%), extraction power (40 - 200 W), extraction time  
133 (10 - 80 min) and solid-liquid ratio (1:10 - 80 g mL<sup>-1</sup>) and is described in detail in Table 3. After  
134 treatment, extracts were centrifuged at 3500 rpm for 10 min and filtered through a Whatman Filter  
135 paper No. #1, and stored in the dark at 4°C for further analysis. Coded variables are shown in  
136 Figure S2.

137 Preliminary experiments were conducted to determine the range of process variables used  
138 in microwave and ultrasound assisted extractions (data not shown). A conventional extraction of  
139 bioactive molecules was also carried out in a laboratory scale shaking incubator at 30°C for 24h.  
140 After shaking incubation, the extracts were centrifuged at 5000g, and the supernatant was collected,  
141 freeze-dried and analyzed for total phenolics.

142 **2.3. Determination of Total Phenolic Content.** Total phenolic content (TPC) was evaluated as  
143 described previously (30), with few modifications. Briefly, an aliquot (20 µL) of the extract was  
144 mixed with 1.58 mL of distilled water. 100 µL of Folin–Ciocalteu reagent was added to the mixture  
145 and incubated for 8 min at room temperature. 300 µL of 10% Na<sub>2</sub>CO<sub>3</sub> was added to it and further  
146 incubated for 30 min in the dark at 40 °C. Absorbance was measured at 765 nm. Blank consisted  
147 of distilled water instead of extract. A gallic acid calibration curve (0 – 100 mg L<sup>-1</sup>) was used to  
148 determine the total phenolic contents, and the results were expressed in gallic acid equivalents, mg  
149 GAE 100 g<sup>-1</sup>.

150 **2.4. Determination of total antioxidant activity.** The antioxidants present in the extract were  
151 measured using the 2,2-diphenyl-1-picrylhydrazyl (DPPH) assay as described previously (32), with  
152 few modifications. An aliquot of 100 µL extracts was allowed to react with 1.4 mL of DPPH radical

153 methanolic solution ( $10^{-4}$  M), followed by 30 min incubation at room temperature. Absorbance was  
154 measured at 517 nm, and the radical scavenging activities were expressed as (Eq. 1):

$$155 \text{ Free Radical Scavenging Activity (\%)} = \frac{A_0 - A_s}{A_0} \times 100 \quad \text{-- Eq. 1}$$

156 where,  $A_0$  and  $A_s$  is the absorbance of the control and sample extract. The control consisted of  
157 distilled water instead of extract.

158 **2.5. Process optimization and statistical analysis.** Optimization was carried out using response  
159 surface methodology (RSM) using the Design Expert Software 7 (Stat-Ease, Inc. USA). The effects  
160 of the four independent variables *i.e.*, solvent concentration, microwave/ ultrasonic power,  
161 extraction time, and solid-liquid ratio, were correlated with the responses *i.e.*, TPC and antioxidant  
162 activity. The experiments were performed at central value to maximize the prediction process and  
163 randomized experimental runs were carried out to prevent unwarranted variability in the responses.  
164 A second-order polynomial equation was fitted in each response to describe the process  
165 mathematically as (Eq. 2):

$$166 Y = \beta_0 + \sum \beta_i X_i + \sum \sum \beta_{ij} X_i X_j + \sum \beta_{ii} X_i^2 \quad \text{-- Eq. 2}$$

167 where,  $\beta_0$  is the coefficient of constant,  $\beta_i$  is the coefficient of linear term,  $\beta_{ii}$  is the coefficient of  
168 quadratic term,  $\beta_{ij}$  is the interaction coefficient of  $i$  and  $j$  variables.  $X_i$  and  $X_j$  are the independent  
169 variables where  $Y$  is the response variable. The second-order polynomial equation was used to build  
170 the response surfaces, and the model adequacy was assessed by the coefficient of  
171 determination ( $R^2$ ), lack of fit, and Fisher test value (F-value) obtained from the analysis of  
172 variance (ANOVA). The models and parameters significance were evaluated at  $p < 0.05$ ,  $p < 0.01$ ,  
173 and  $p < 0.001$ . The actual and coded values are listed in Table S1 and Table S2. The optimization

174 procedure followed maximizing the responses, *i.e.*, TPC and antioxidant activity, using the  
175 response surface methodology. The predicted solution was revalidated by conducting experiments  
176 at the optimized levels.

177 **2.6. High performance liquid chromatography (HPLC).** Berberine is the main phytochemical in  
178 *Coptis teeta* (4). Separation and quantification of berberine was carried out in a Waters HPLC  
179 system equipped with a UV-Vis detector (Waters, USA). Samples were prepared in HPLC-grade  
180 methanol and filtered through a 0.22  $\mu\text{m}$  nylon filter before analysis. The separations of the samples  
181 were carried out in a Symmetry 300<sup>TM</sup> C<sub>18</sub> column (4.6 mm  $\times$  250 mm) where 0.05% aqueous  
182 ortho-phosphoric acid and acetonitrile were used as solvents A and B, respectively. The gradient  
183 elution method of Kamal and coworkers (33) was used, and flowrate was maintained at 1 mL min<sup>-1</sup>,  
184 and the sample volume used for analysis was 20  $\mu\text{L}$ . Absorbance was measured at 266 nm.

### 185 3. Results and discussions

186 Microwave-assisted extraction of phenolics from *Coptis teeta* rhizomes will be discussed first,  
187 followed by ultrasound-assisted extraction. Particular attention is paid to the effects of extraction  
188 parameters, including solvent concentration (water: methanol), microwave/ultrasound power  
189 levels, extraction time, and solid-liquid ratio on total phenolic content and antioxidant activity of  
190 the extracts. This is followed by the modeling and optimization of the process, along with the  
191 quantification of berberine in the optimized extracts using high-performance liquid  
192 chromatography. This sets the scene for discussing the effect of independent variables on the  
193 responses and recommending standardised methods and solvent concentrations for preparing  
194 *Coptis teeta* extracts in food and nutraceutical industry applications.

195 **3.1. Effect of microwave extraction on total phenolics and antioxidant activity.** The results  
196 obtained during microwave-assisted extraction for total phenolic content (TPC) and antioxidant  
197 activity by DPPH assay are shown in Table 1. The highest phenolic extraction was uncovered at  
198 60% solvent concentration, extraction time of 30 min, 1:25 g mL<sup>-1</sup> solid-liquid ratio, and 180 W  
199 microwave power, leading to maximum extraction of total phenolics, *i.e.*, 209.61 ± 3.15 mg GAE  
200 100 g<sup>-1</sup>. The highest antioxidant activities by DPPH assay (*i.e.*, 98.30 ± 2.12%) was achieved using  
201 60% solvent concentration, 30 min extraction time, 1:40 g mL<sup>-1</sup> solid-liquid ratio, and microwave  
202 power of 540 W.

203 Results from ANOVA show that all the independent variables were significantly  
204 responsible for the increase in TPC and antioxidant values (Table 2). Figures 1 and 2a - c show  
205 decreased phenolic content and antioxidant activity with increased solvent concentration. The  
206 difference is attributed to progressively reducing solvent polarity, where lower extraction rates  
207 were observed at higher methanol concentrations. Diluted solvents in MAE applications have

208 proven effective for recovering phytochemicals (34), and is an important parameter in this study as  
209 high polarity of the protoberberine alkaloids present in *Coptis teeta* has been reported earlier (14).  
210 Since water is more polar compared to methanol, *i.e.*, the latter contains a non-polar methyl group,  
211 and the C-O bond in methanol is less polar compared to the O-H bond of water. It appears that an  
212 increase in methanol concentration beyond 60% contributes negatively to the extraction of  
213 phenolics. Teng and Choi have also reported that the extraction of phenolics was greater at 60%  
214 ethanol concentration from *Coptis chinensis* Franch (27). To compare the results between methanol  
215 used in the present study, and ethanol in the study by Teng and Choi (27), further measurements  
216 were made for phenolics extraction using the two solvents. Our results demonstrated a TPC of  
217  $422.50 \pm 2.57$  mg GAE  $100\text{g}^{-1}$ ,  $342.00 \pm 3.65$  mg GAE  $100\text{g}^{-1}$ , and  $102.00 \pm 1.58$  mg GAE  $100\text{g}^{-1}$   
218 for 70% aqueous methanol, 70% aqueous ethanol, and water, respectively. This demonstrates that  
219 aqueous methanol is superior to aqueous ethanol for extracting phenolics from *Coptis teeta*. It is of  
220 note that although TPC was greater for conventional solvent-based extraction, the goal of the  
221 present study was to minimize the process duration while ensuring maximum phenolic extraction  
222 for industrial suitability. Hence, the extraction time for maximized extraction of phenolics was  
223 optimized. Under the MAE conditions, phenolic and antioxidant activities in the extract were seen  
224 to increase gradually with an increase in extraction time, with maximal values at 30 min (Table 1).  
225 Further increase in extraction time was not modelled as longer durations led to plateauing followed  
226 by a reduction in TPC (data not shown). It is postulated that increased extraction time led to thermal  
227 degradation of phenolics in the extract (35). Increased release of phenolics and antioxidants was  
228 seen with a gradual increase in extraction time, as depicted in Figures 1 and 2a, d - e. Our results  
229 highlight that the MAE process achieved comparable phenolic extraction within 30 min, which  
230 would take roughly 12-24 hours using the conventional solvent extraction method (36).

231 Additionally, maximum phenolics and antioxidant activities were achieved at greater solid-  
232 liquid ratios (Table 1, and Figures 1b, d, f and 2b, d, f), consolidating the importance of solid-liquid  
233 ratio in phenolics extraction. Initially, lower extraction rates were observed at the lower solid-liquid  
234 ratio, followed by maximal extraction at higher values of the solid-liquid ratio, shown in Figures  
235 1, 2b, d - f. The lower extraction rates at low solid-liquid ratios might be attributed to the  
236 intermittent distribution of microwave heating in a partially soaked sample, as also suggested in  
237 previous studies (37, 38). Our results are concurrent with *Pistacia lentiscus* L. where the  
238 researchers reported maximal phenolics release ( $185.69 \pm 18.35$  mg GAE g<sup>-1</sup> dry weight) at higher  
239 solid-liquid-ratio of 1:28 g mL<sup>-1</sup> (39). Microwave power was also observed to affect the phenolic  
240 extraction (Table 1). At short extraction time, phenolic extraction increased proportionally to  
241 microwave power (Figure 1, 2c, e - f). The opposite was observed when a longer extraction time  
242 was used (Figure 1, 2c, e - f) and could be attributed to thermal degradation of phytochemicals  
243 resulting from higher microwave power in tandem with extraction time, and has been reported  
244 earlier (34). Teng and Choi also reported that 180 W microwave power in combination with 5 min  
245 irradiation time was optimal for maximizing the extraction of alkaloids from *Coptis chinensis*  
246 Franch (27).

247

248 Table 1. Experimental design parameters and responses for microwave-assisted extraction (MAE)  
249 from *Coptis teeta* Wall.

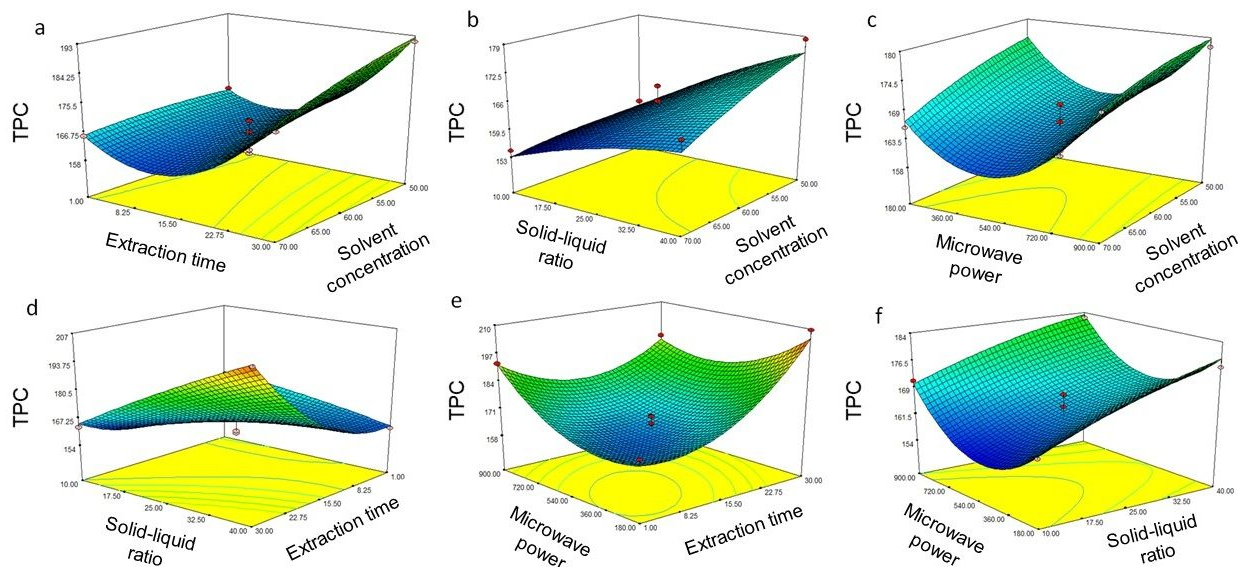

Run number	Solvent concentration (%)	Extraction time (min)	Solid-liquid ratio (g mL <sup>-1</sup> )	Microwave power (W)	TPC* (mg GAE/100 g)	Antioxidant activity (%)

265 scavenging activity.

266  
267 The linear, quadratic, and their interaction terms were calculated to describe the response  
268 variables (Table 2). The developed models for dependent variables (*i.e.*, TPC, antioxidant activity;  
269 Eq. 3 and 4) were evaluated for their significance using ANOVA. The model was found to be  
270 significant, and the lack of fit was not significant.  $R^2$  values were 0.96 and 0.98. The final equations  
271 for TPC and antioxidant activity in terms of coded factors are depicted below:

$$272 \quad TPC = 163.96 - 3.59 * X_1 + 9.67 * X_2 + 7.53 * X_3 + 2.79 * X_4 - 0.99 * X_1^2 + 13.41 * X_2^2 - 1.39 * X_3^2$$

$$273 \quad + 11.41 * X_4^2 - 2.79 * X_1 * X_2 - 2.65 * X_1 * X_3 + 1.00 * X_1 * X_4 + 13.59 * X_2 * X_3 - 10.00 * X_2 * X_4 -$$

$$274 \quad 0.88 * X_3 * X_4 \quad \text{-- Eq. 3}$$

$$275 \quad \text{Antioxidant activity} = 81.58 - 0.77 * X_1 + 1.90 * X_2 + 1.88 * X_3 + 1.27 * X_4 + 6.97 * X_1^2 + 5.90 * X_2^2$$

$$276 \quad + 6.42 * X_3^2 + 1.65 * X_4^2 - 0.65 * X_1 * X_2 - 0.90 * X_1 * X_3 + 0.65 * X_1 * X_4 + 0.69 * X_2 * X_3 - 1.11 * X_2 * X_4$$

$$277 \quad - 0.21 * X_3 * X_4 \quad \text{-- Eq. 4}$$

278 where,  $X_1$ ,  $X_2$ ,  $X_3$ , and  $X_4$  represent solvent concentration, extraction time, solid-liquid ratio, and  
279 microwave power. The coefficient determines the intensity of the response. Note that the positive  
280 coefficient depicts an increase in response with an increase in variable, whereas the negative  
281 coefficient depicts a decrease in response with an increase in variable. For microwave-assisted  
282 extraction (MAE), the optimal conditions were: 65% solvent concentration, 310 W power, 30 min  
283 extraction time, and 1:39 g mL<sup>-1</sup> solid-liquid ratio, resulting in TPC of 210.04 mg GAE 100g<sup>-1</sup> and  
284 antioxidant activity of 98.57%.

289

290 **3.2. Effect of ultrasound extraction on total phenolics and antioxidant activity.** The TPC and  
291 antioxidant activity from *Coptis teeta* rhizomes varied from  $66.18 \pm 3.12$  to  $276.20 \pm 2.54$  mg GAE  
292  $100 \text{ g}^{-1}$  and  $70.06 \pm 1.75$  to  $97.68 \pm 3.09\%$ , respectively, during the ultrasound-assisted extraction  
293 process (Table 3). The highest phenolic content was observed for the extracts using 50% aqueous  
294 methanol as the extraction solvent with 80 min sonication time,  $1:10 \text{ g mL}^{-1}$  solid-liquid ratio, and  
295 120 W ultrasound power. Meanwhile, antioxidant activity by DPPH scavenging assay was highest  
296 when 50% aqueous methanol was used in a  $1:80 \text{ g mL}^{-1}$  solid-liquid ratio and 120 W ultrasound  
297 power for a period of 10 min.

298 Solvent concentration is an important parameter on which the extraction of phenolic  
299 compounds depends. An investigation of the effect of methanol in water at various percentages (0  
300 - 100%) was conducted to extract phenolics, as depicted in Table 3. Firstly, 50% solvent  
301 concentration, *i.e.*, 50% aqueous methanol, was observed to maximize the extraction of phenolics  
302 ( $276.20 \pm 2.54$  mg GAE  $100 \text{ g}^{-1}$ ) as revealed by TPC assay and antioxidant activity ( $97.68 \pm$   
303  $3.09\%$ ), while phenolics extraction suffered at higher solvent concentrations (Fig 3 and 4a – c).  
304 Our results agree with recent reports showing phytochemical extraction from *Coptis chinensis*  
305 Franch. increased with an increase in ethanol concentration, reaching a peak at an ethanol  
306 concentration of 50% (27, 28). Dilute solvents in UAE applications have also proven effective for  
307 recovering phytochemicals from other plant materials, such as *Hancornia speciosa* (34).  
308 Additionally, extraction time had little effect on total phenolic extraction or the antioxidant activity  
309 of the extracts (Table 3) and agrees with previous reports (27, 28). However, when comparing the  
310 effect of solid-liquid ratios with extraction time, the latter was observed to lead to a decline in total  
311 phenolics and antioxidant activity of the extracts (Fig 3 and 4a, d – e). Here, an increase in solid-  
312 liquid ratio from  $1:10$  to  $1:80 \text{ g mL}^{-1}$  resulted in increased total phenolics from  $72.40 \pm 3.50$  mg

313 GAE 100 g<sup>-1</sup> to 258.98 ± 3.12 mg GAE 100 g<sup>-1</sup>, and antioxidant activity from 71.82 ± 2.75% to  
314 97.68 ± 3.09%, respectively (Table 3). Response surface graphs illustrate the effects of interaction  
315 of independent variables and are shown in Figures 3 and 4c, e - f. It can be seen from the figures  
316 that an increase in solid-liquid ratio, decreased phenolic content and antioxidant activity.  
317 Additionally, up to 120 W for microwave power, total phenolics and antioxidant activity increased  
318 (Table 3). However, above 120 W power, a sharp decline in phenolics and antioxidant activity was  
319 seen (Figures 3 and 4b, d – f). Correlation between sonochemical effects of ultrasonic fields,  
320 phenolic extraction, and phenolic degradation have been reported previously (40). Free radical  
321 scavengers have been reported to greatly inhibit the degradation of phenolics during such extraction  
322 processes (40) and could be an area for further research, but is beyond the scope of the present  
323 study.

324

341 power and solid-liquid ratio. DPPH: 2,2-diphenyl-1-picrylhydrazyl free radical scavenging  
342 activity.

343  
344 To describe the response variables, the linear and quadratic terms, along with their  
345 interaction terms, were calculated (Table 4). The developed models for dependent variables (*i.e.*,  
346 TPC, antioxidant activity; Eq. 5 and 6) were evaluated for their significance using ANOVA. The  
347 quadratic model was found to be significant.  $R^2$  were 0.98 and 0.97, and lack of fit was not  
348 significant. The predicted equations for TPC and antioxidant activity are shown below:

$$349 \quad TPC = 248.60 + 16.90 * X_1 - 0.14 * X_2 + 9.90 * X_3 - 20.42 * X_4 - 68.14 * X_1^2 - 5.07 * X_2^2 - 34.38 * X_3^2 -$$

$$350 \quad 50.86 * X_4^2 - 3.14 * X_1 * X_2 - 16.34 * X_1 * X_3 - 58.85 * X_1 * X_4 + 13.88 * X_2 * X_3 - 74.51 * X_2 * X_4 + 13.97 *$$

$$351 \quad X_3 * X_4 \quad \text{-- Eq. 5}$$

$$352 \quad \textit{Antioxidant activity} = 92.65 + 2.90 * X_1 - 1.63 * X_2 + 0.81 * X_3 + 1.47 * X_4 - 12.41 * X_1^2 + 0.87 *$$

$$353 \quad X_2^2 + 1.12 * X_3^2 - 0.24 * X_4^2 + 4.24 * X_1 * X_2 + 4.61 * X_1 * X_3 + 1.74 * X_1 * X_4 - 0.74 * X_2 * X_3 - 1.34 * X_2 * X_4 +$$

$$354 \quad 1.29 * X_3 * X_4 \quad \text{-- Eq. 6}$$

355 where,  $X_1$ ,  $X_2$ ,  $X_3$ , and  $X_4$  represent solvent concentration, extraction time, ultrasound power, and  
356 solid-liquid ratio. Results showed that for ultrasound-assisted extraction (UAE), 36% solvent  
357 concentration, 160 W ultrasound power, 10 min extraction time, 1:78 g mL<sup>-1</sup> solid-liquid ratio  
358 resulted in TPC of 251.11 mg GAE 100g<sup>-1</sup> and 97.82% antioxidant activity.

359

365 *MAE, Microwave-assisted extraction; UAE, ultrasound-assisted extraction; GAE, gallic acid equivalent. n = 5.*366  
367 **3.3. Model validation and comparison between microwave and ultrasound assisted methods.**

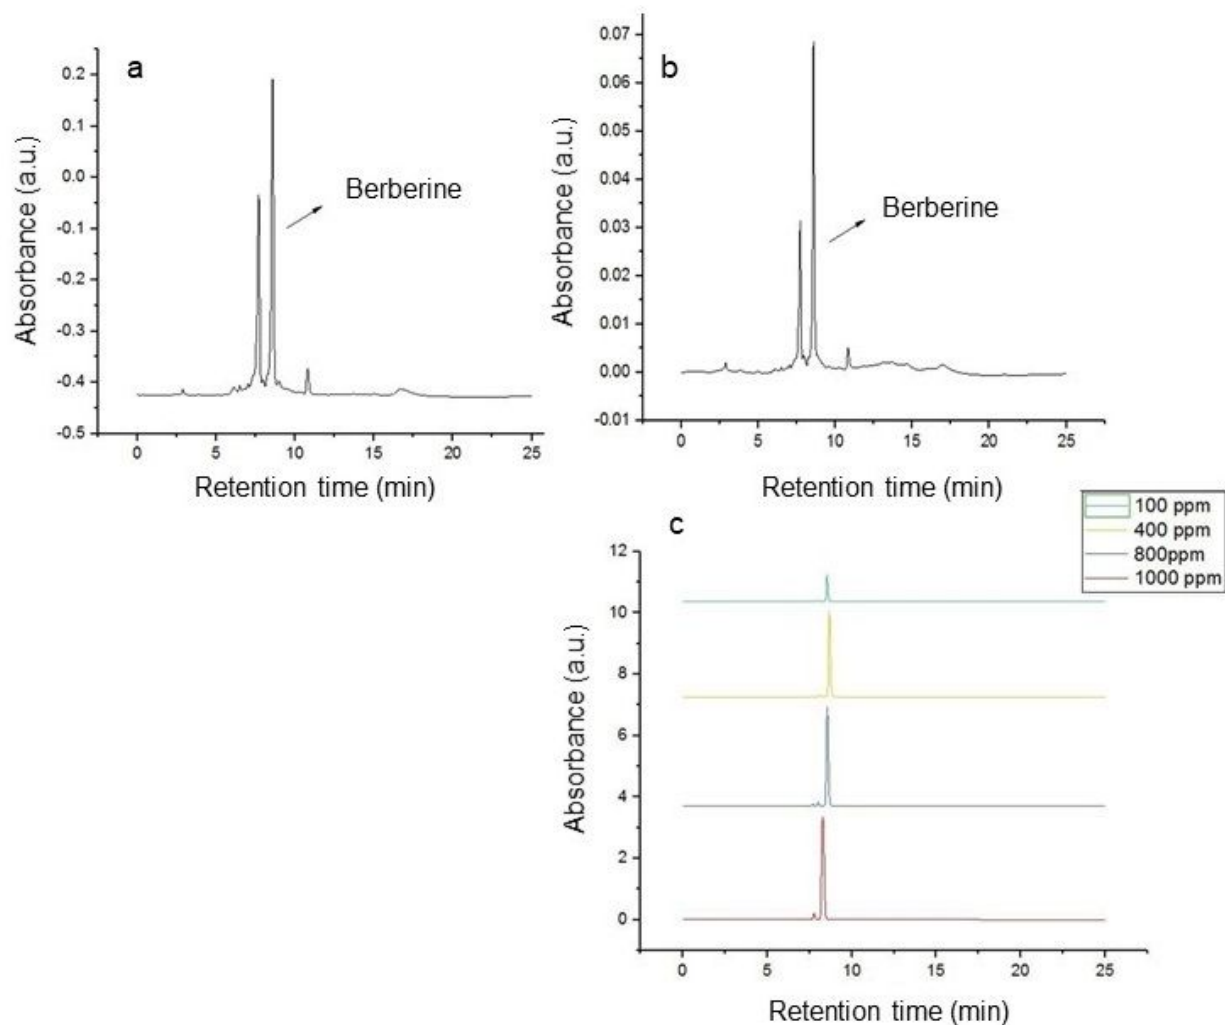

368 The models developed using response surface methodology were revalidated by mean variation  
369 and percentage variation among the total phenols and antioxidant activity values. For validation,  
370 rhizomes of *Coptis teeta* were extracted in the optimal microwave and ultrasound-assisted  
371 extraction conditions, and are shown in Table 5. Extraction yields were greater for recovery of  
372 phenolics and antioxidant activity in the case of ultrasound-assisted extraction, compared to  
373 microwave-assisted extraction. Our results contradict the reports on MAE and UAE of *Coptis*  
374 *chinense* Franch., where MAE treatment was found to be superior for the extraction of alkaloids,  
375 compared to UAE (27, 28). The authors reported 33.394 and 16.57 g BCE 100g<sup>-1</sup> for MAE and  
376 UAE, respectively (27, 28). The observed differences may be attributed to variations in plant genus,  
377 specifically *Coptis chinense* Franch. versus *Coptis teeta* Wall., as well as differences in analysis  
378 design *i.e.*, total phenolics versus total alkaloids. Further study is necessary to elucidate the  
379 structural changes occurring in the plant cellular matrix during the application of MAE and/or UAE  
380 and streamlining experimental and analysis designs for further conclusions.

381 Berberine content in the phenolic extracts was also quantified using high-performance  
382 liquid chromatography under optimized conditions for MAE and UAE, and are shown in Figure 5a

383 - b. As described in the introduction section, berberine is known to be the main phytochemical  
384 constituent in *Coptis teeta*, and one of our goals was to ascertain if the increase in phenolics content  
385 after the MAE and/or UAE treatments tandemly increased berberine content in the extracts. Figure  
386 5a - b shows that berberine was the most abundant phytochemical in both extracts. The standard  
387 curve for berberine used in the quantification is shown in Figure 5c. The highest concentration of  
388 berberine was observed in extracts obtained using microwave-assisted extraction technique (212.18  
389 ppm) followed by ultrasound-assisted extraction technique (162.96 ppm). Ultrasound treatment led  
390 to lower berberine content, although overall, higher phenolic extraction was achieved. Teng and  
391 Choi reported higher berberine extraction using UAE treatment, however, longer extraction time  
392 were employed (*i.e.*, 60 min sonication time compared to 10 min in this study). However, the lower  
393 amount of berberine in the extracts prepared using our UAE method corroborates the lower  
394 antioxidant activity of the UAE extract, although the total phenolic content was higher when  
395 compared to the MAE extract. Further work is necessary to elucidate the effects of MAE and UAE  
396 methods on berberine extraction.

397

398 Figure 5: HPLC chromatogram of the optimized sample using (a) microwave-assisted extraction,  
399 (b) ultrasound-assisted extraction, and (c) offset concentration series for standard berberine.

#### 400 4. Conclusion.

401 In conclusion, using microwave (MAE) and ultrasound (UAE) assisted extraction in combination  
402 with the Box-Behnken design-based modeling and response surface optimization routine  
403 effectively increased the total phenolics yield and antioxidant activity of *Coptis teeta* Wall. extracts.  
404 The study statistically optimized the effects of independent variables (solvent concentration,  
405 microwave/ultrasound power, extraction time, and solid-liquid ratio) on the resulting responses,  
406 *i.e.*, total phenolic content and antioxidant activity, and is an improvement on existing literature.  
407 Notably, UAE proved superior in recovering total phenolics, whereas MAE yielded higher  
408 berberine content. The findings underscore the importance of selecting an extraction technique  
409 based on targeted phytochemicals and end-use requirements. Further work is necessary to elucidate  
410 the effects of MAE and UAE methods on berberine extraction, as well as other valuable  
411 phytochemicals which are known to be present in the *Coptis* species, such as palmatine,  
412 jatrorrhizine, coptisine, columbamine, and epiberberine. The current findings from this study  
413 provide a platform for future industrialization of standardized methods and solvent concentration  
414 for tailored phytochemical extraction from *Coptis teeta*, as well as guide further studies in other  
415 plant materials.
