# High performance photodetectors based on $\text{In}_2\text{S}_3$ , $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ and $\text{In}_2\text{Se}_3$ nanostructures†

Ankurkumar J. Khimani,<sup>a</sup> Sujit A. Kadam,<sup>b</sup> Ranjan Kr. Giri,<sup>c</sup>  
Chetan K. Zankat<sup>d</sup> and Yuan-Ron Ma<sup>b</sup>

One-dimensional (1D) nanostructures, including nanofibers, nanocubes, and nanoplates of  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  semiconductors, were synthesized using a hydrothermal technique for studying their photodetector behaviour. Photocurrent measurements demonstrate that semiconducting  $\text{In}_2\text{Se}_3$  1D nanofibers display an exceptional response to white light, with a photo responsivity of  $185.8 \text{ mA W}^{-1}$  and a detectivity of  $22.6 \times 10^9$  Jones, which is four times greater than that of  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures. The response times of the  $\text{In}_2\text{Se}_3$  photodetectors are impressively short, measuring only 8.8 seconds. The superior responsivity detectivity and faster response time of the 1D  $\text{In}_2\text{Se}_3$  nanofibers can be attributed to their large surface area, which boosts light absorption and facilitates efficient charge transfer, thereby enhancing the overall device performance.

## 1. Introduction

Layered transition metal dichalcogenides (TMDCs), graphene and black phosphorus have attracted research due to their new and different physical properties, exceptional structure and promising applications.<sup>1–8</sup> In the field of photovoltaic development, the substitute of lethal materials with eco-friendly materials is a crucial requirement. In thin film solar cell production, using CdS as a buffer layer led to the highest efficiency of 21.7%.<sup>9,10</sup> Nevertheless, in large-scale manufacturing, cadmium sulfide causes ecological damage owing to significant toxicity. Ergo, in these times it is essential to replace CdS with eco-friendly materials. As an alternative to potentially hazardous materials (CdS, PbS, CdTe, *etc.*), compound semiconductors like  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{Se}_3$ , ZnO, ZnSe, SnS, SnS<sub>2</sub>, *etc.* are abundant.<sup>11–15</sup> Among all compounds,  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{Se}_3$  could be the best choice for optoelectronic device fabrication owing to their photoconductive character, non-toxicity, elevated optical transmittance in the visible range (70–80%), wider band gap (2.1 to 2.7 eV) and low production cost.<sup>16,17</sup> Indium selenide ( $\text{In}_2\text{Se}_3$ ) and indium sulphide ( $\text{In}_2\text{S}_3$ ) are n-type semiconductors

from the III–VIA group and have recently gained popularity due to their exceptional charge transport properties, superior mechanical flexibility, and strong light–matter interactions.<sup>18–21</sup>  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{Se}_3$  have frequently shown different valence-varying structures with different crystalline phases, such as  $\alpha$ - $\text{In}_2\text{S}_3$ ,<sup>22</sup>  $\beta$ - $\text{In}_2\text{S}_3$ ,<sup>23</sup>  $\gamma$ - $\text{In}_2\text{S}_3$ ,<sup>24</sup>  $\kappa$ - $\text{In}_2\text{S}_3$ ,<sup>25</sup>  $\alpha$ - $\text{In}_2\text{Se}_3$ ,  $\beta$ - $\text{In}_2\text{Se}_3$ , and  $\gamma$ - $\text{In}_2\text{Se}_3$ .<sup>26</sup> The materials  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{Se}_3$  are currently under discussion as potential possibilities for a wide range of applications including photodetectors,<sup>27</sup> solar cells,<sup>28</sup> photoelectrocatalytic water splitting,<sup>29</sup> gas sensors,<sup>30</sup> electromechanical devices and piezotronic sensors,<sup>31</sup> electronic skin strain sensors,<sup>32</sup> electroresistance switching in ferroresistive memory junctions,<sup>33</sup> *etc.* Furthermore, the extraordinary properties of  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{Se}_3$  make them more advantageous in various applications than metal oxides such as CuO, ZnO, and  $\text{Fe}_2\text{O}_3$ .<sup>34</sup>

Indium sulphide occurs in three different crystal forms in nature. The yellow  $\alpha$ - $\text{In}_2\text{S}_3$  having a cubic structure is stable at temperatures above 422 °C. The spinel structure material  $\beta$ - $\text{In}_2\text{S}_3$  (red) is stable at room temperature. The layer structure of  $\gamma$ - $\text{In}_2\text{S}_3$  is unaffected by temperatures exceeding 775 °C. Among these three,  $\alpha$ - $\text{In}_2\text{S}_3$  is given the most consideration since it crystallises in a spinel shape and is stable at room temperature despite its high vacancy density.<sup>35,36</sup>

Indium selenide exists in six crystallographic forms in nature, *i.e.* the hexagonal and rhombohedral structure of  $\alpha$ - $\text{In}_2\text{Se}_3$ , hexagonal and rhombohedral structure of  $\beta$ - $\text{In}_2\text{Se}_3$ , hexagonal structure of  $\gamma$ - $\text{In}_2\text{Se}_3$  and triclinic structure of  $\delta$ - $\text{In}_2\text{Se}_3$ . Temperature-dependent phase transitions for bulk  $\text{In}_2\text{Se}_3$  consist of the  $\alpha$ - $\text{In}_2\text{Se}_3$  to  $\beta$ - $\text{In}_2\text{Se}_3$  phase transition at 200 °C, the  $\beta$ - $\text{In}_2\text{Se}_3$  to  $\gamma$ - $\text{In}_2\text{Se}_3$  phase transition at 520 °C, and the  $\gamma$ - $\text{In}_2\text{Se}_3$  to  $\delta$ - $\text{In}_2\text{Se}_3$  transition at 730 °C.<sup>37,38</sup> Individual

sheets or layers of  $\alpha$  and  $\beta$  phases have five sporadic sub-layers of indium and selenium atoms. van der Waals interaction allows bordering layers to combine. Vacancies are arranged in a screw pattern on every third In site, making the  $\gamma$ -phase a defective wurtzite structure. Different configurations of the vacancy screws allow it to crystallise in one of many different space groups, including  $P6_1$ ,  $P6_5$ ,  $P6_122$ , or  $P6_522$ .<sup>39,40</sup>

There are plenty of forms of Indium sulfide and Indium selenide available, such as self-assembled porous 3D flowerlike  $\beta$ - $\text{In}_2\text{S}_3$ ,<sup>41</sup> nanoparticles of  $\text{In}_2\text{S}_3$ ,<sup>42</sup>  $\beta$ - $\text{In}_2\text{S}_3$  nanoplates,<sup>43</sup> 1D  $\beta$ - $\text{In}_2\text{S}_3/\text{In}_2\text{O}_3$  micro-tubes,<sup>44</sup>  $\text{In}_2\text{S}_3$  thin film,<sup>45</sup>  $\text{In}_2\text{S}_3/\text{BiOI}$  composites,<sup>46</sup> Ni-doped  $\text{In}_2\text{S}_3$  powders,<sup>47</sup> nanosheets of  $\text{In}_2\text{S}_3/\text{S-C}_3\text{N}_4$  dots,<sup>48</sup>  $\text{In}_2\text{S}_3$  quantum dots,<sup>49,50</sup>  $\text{In}_2\text{S}_3$  single crystal,<sup>51,52</sup>  $\gamma$ - $\text{In}_2\text{S}_3$  and  $\beta$ - $\text{In}_2\text{S}_3$  colloidal nanoplatelets,<sup>26</sup> hierarchical  $\text{Bi}_2\text{S}_3/\text{In}_2\text{S}_3$  core/shell microspheres,<sup>53</sup>  $\text{In}_2\text{Se}_3$  nanowires,<sup>54</sup> monolayer  $\beta$ - $\text{In}_2\text{Se}_3$  nanosheets,<sup>55</sup> etc.

In this work, a high-yield hydrothermal technique was utilized to synthesize nanostructures and 1D nanofibers of  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  and  $\text{In}_2\text{Se}_3$ . The use of sonic waves in the sonochemical technique prevented aggregation of the nanostructures and 1D nanofibers during the growth process, resulting in high-quality products. The nanostructures and 1D nanofibers were systematically characterized for their chemical composition, structure, morphology, etc. Photodetectors based on the as-grown product were fabricated and investigated

systematically. The results of photocurrent measurements indicate that 1D nanofibers made of semiconducting  $\text{In}_2\text{Se}_3$  exhibit an outstanding response to white light, showing a photo-responsivity of  $180.5 \text{ mA W}^{-1}$ . This value is four times higher than the photo-responsivity of  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures.

## 2. Experimental

### 2.1. Chemicals

Indium(III) chloride tetrahydrate ( $\text{InCl}_3 \cdot 4\text{H}_2\text{O}$ ) [ $\sim 99.99\%$ , Sisco Research Laboratories (SRL) Pvt. Ltd, India], thioacetamide ( $\text{C}_2\text{H}_5\text{NS}$ ) [ $\sim 99.00\%$ , Sisco Research Laboratories (SRL) Pvt. Ltd, India], selenium dioxide ( $\text{SeO}_2$ ) [ $\sim 98.00\%$ , HiMedia Laboratories Pvt. Ltd, Mumbai, India], *N*-cetyl-*N,N,N*-trimethylammonium bromide (CTAB) [ $\sim 99.00\%$ , HiMedia Laboratories Pvt. Ltd, Mumbai, India], and hydrazine monohydrate ( $\text{NH}_2\text{NH}_2 \cdot \text{H}_2\text{O}$ ) [ $\sim 98.00\%$ , Sigma-Aldrich, United States].

### 2.2. Synthesis of $\text{In}_2\text{S}_3$ nanostructures

Initially, 20 mL of 0.5 M  $\text{InCl}_3 \cdot 4\text{H}_2\text{O}$  (2.06 g) is mixed with 20 mL of 0.5 M  $\text{C}_2\text{H}_5\text{NS}$  (0.22 g) under constant stirring for 30 minutes. The aforementioned solution is then augmented with 1.08 g of 0.2 M surfactant CTAB. The solution is then placed in a double-walled stainless steel vertical autoclave

#### Pathway I: Reaction pathway for the synthesis of $\text{In}_2\text{S}_3$

Fig. 1 The reaction pathway for the synthesis of  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{Se}_3$  and  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures.

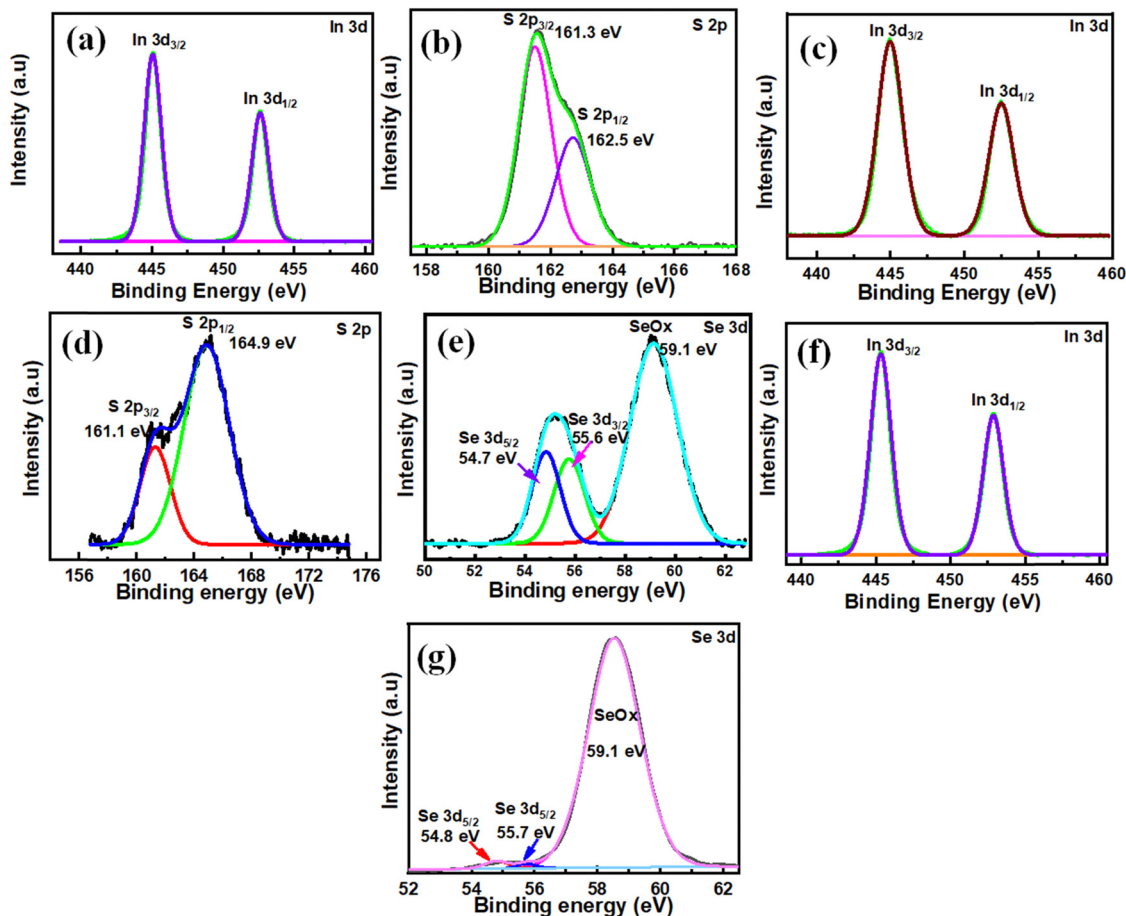

Fig. 2 (a) and (b) The core level spectra of indium (In 3d) and sulfur (S 2p) in  $\text{In}_2\text{S}_3$  nanostructures. (c)–(e) The core level spectra of indium (In 3d), sulfur (S 2p), and selenium (Se 3d) in  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures. (f) and (g) The core level spectra of indium (In 3d) and selenium (Se 3d) in  $\text{In}_2\text{Se}_3$  nanostructures.

(operating at 383 K for 12 hours, with a pressure range of 10–12 bar, 230 V, 50–60 Hz, and 2 kW). The final solution takes on a yellow hue. The precipitates are then filtered *via* Grade-5 filter paper. Multiple washes are used to remove contaminants from the yield before it is dried in an oven for 10 hours at 318 K.

### 2.3. Synthesis of $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ nanostructures

At first, 20 mL of 0.5 M  $\text{InCl}_3 \cdot 4\text{H}_2\text{O}$  (1.70 g) is mixed with 20 mL of 0.5 M  $\text{SeO}_2$  (0.33 g) and stirred for 30 minutes. After 30 minutes of stirring, 20 mL of 0.5 M  $\text{NH}_2\text{NH}_2 \cdot \text{H}_2\text{O}$  (0.26 g) is introduced to the solution. After that 20 mL of 0.5 M  $\text{C}_2\text{H}_5\text{NS}$  (0.09 g) is added to the solution under stirring for 30 minutes. Finally, 0.54 g of surfactant CTAB (0.2 M) is added to the aforesaid mixture. The prepared solution is placed into the vertical autoclave under the same circumstances as previously stated. The final product has a brownish-yellow hue. The filtration and drying conditions remain constant.

### 2.4. Synthesis of $\text{In}_2\text{Se}_3$ nanostructures

Initially, 20 mL of 0.5 M  $\text{InCl}_3 \cdot 4\text{H}_2\text{O}$  (1.44 g) is mixed with 20 mL of 0.5 M  $\text{SeO}_2$  (0.56 g) under steady stirring for 30 minutes. After 30 minutes of stirring, 20 mL of 0.5 M  $\text{NH}_2\text{NH}_2 \cdot \text{H}_2\text{O}$  (0.51 g) is introduced to the solution. The aforementioned

solution is then augmented with 0.18 g of surfactant CTAB at a concentration of 0.2 M. Under the same conditions, it is then transferred to the vertical autoclave. A brownish hue develops in the final solution. The process of filtration and drying does not change.

### 2.5. Reaction mechanism

The reaction mechanism of indium sulfide ( $\text{In}_2\text{S}_3$ ), indium selenide ( $\text{In}_2\text{Se}_3$ ), and mixed indium sulfoselenide ( $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ ) compounds can be described as follows as shown in Fig. 1. The formation mechanism of InS and InSe can be described through pathway I and pathway II, respectively. In the case of  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , the reaction mechanism combines the pathways for  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{Se}_3$ . The sulfur and selenium atoms simultaneously react with indium atoms, leading to the formation of indium sulfoselenide, as depicted in pathway III.

## 3. Results and discussion

### 3.1. X-ray photoelectron spectroscopy (XPS)

The electronic states and chemical composition of the surface of the  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  nanostructures were studied using XPS and exhibited in Fig. 2. Fig. 2(a and b) displays

Fig. 3 The XRD patterns of (a)  $\text{In}_2\text{S}_3$ , (b)  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and (c)  $\text{In}_2\text{Se}_3$  nanostructures.

Fig. 4 Surface morphology and size distribution analysis of (a) and (b)  $\text{In}_2\text{S}_3$  nanostructures, (c) and (d)  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures and nanoplates, and (e) and (f)  $\text{In}_2\text{Se}_3$  nanofibers, and (g) EDS mapping of  $\text{In}_2\text{Se}_3$  nanofibers.

an XPS spectrum of  $\text{In}_2\text{S}_3$  nanostructures. The survey spectra exhibit the presence of In, S, and C elements, as shown in Fig. S1(a) (ESI<sup>†</sup>). The XPS spectra of the In 3d core level are further decomposed into two peaks at the binding energy of 445 eV and 452.6 eV corresponding to In 3d<sub>5/2</sub> and In 3d<sub>3/2</sub>,<sup>56</sup> as depicted in Fig. 2(a). The S 2p spectrum (Fig. 2b) shows two peaks at 161.3 eV and 162.5 eV, corresponding to S 2p<sub>3/2</sub> and S 2p<sub>1/2</sub>. On the other hand, Fig. 2(c–e) demonstrates the  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructure XPS spectra. The survey spectrum of  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  showing the presence of In, S, Se, and C elements is depicted in Fig. S1 (b) (ESI<sup>†</sup>). In the XPS spectrum of In 3d, the main peaks observed at 445 eV and 452.6 eV correspond to In 3d<sub>5/2</sub> and In 3d<sub>3/2</sub> core levels, as shown in Fig. 2(c). Moreover, spectrum S 2p, as depicted in Fig. 2(d), reveals four peaks at 161.1 eV and 162.3 eV, corresponding to S 2p<sub>3/2</sub> and S 2p<sub>1/2</sub>. The peaks at 163.7 eV and 164.9 eV are attributed to S 2p<sub>3/2</sub> and S 2p<sub>1/2</sub> of S in C–S, respectively. Also, Fig. 2(e) shows that the Se 3d peaks are located at 54.8 eV and 55.7 eV, respectively.<sup>57</sup> Additionally, Se–O bonding structures at 59.1 eV confirm the oxidation of Se species ( $\text{SeO}_2$ ) on the surface.<sup>57</sup> Furthermore, Fig. 2(f and g) demonstrates pristine  $\text{In}_2\text{Se}_3$  nanostructure XPS spectra. The survey spectra of In, Se and C elements are shown in Fig. S1(c) (ESI<sup>†</sup>). In the high-resolution In 3d spectrum, the binding energies at 445 eV and 552.6 eV are attributed to the In 3d<sub>5/2</sub> and In 3d<sub>3/2</sub>, as depicted in Fig. 2(f). In the spectrum of Se 3d, two small peaks for binding energies at 54.8 eV and 55.7 eV are observed for Se–Se bonds. Also, the 59.1 eV peak is consistent with  $\text{SeO}_x$ , as shown in Fig. 2(g). The  $\text{SeO}_x$  peak shows a good signal compared to the Se–Se bonds, indicating that the Se–Se bonds are fragile. However, there is a very tiny

chemical shift, which means that the In, S, and Se valence states are still stable for  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  nanostructures.<sup>57,58</sup>

### 3.2. X-ray diffraction (XRD)

The XRD profile of the nanostructures is shown in Fig. 3. The patterns are recorded in a range of  $2\theta$  from  $10^\circ$  to  $80^\circ$ . The observed peaks are sharp at the top and have broad width at half maxima indicating that the nanoforms are of good polycrystallinity having fine grains. From the analysis,  $\text{In}_2\text{S}_3$  nanostructures possess a hexagonal structure of the unit cell with lattice parameters  $a = b = 7.6231 \text{ \AA}$ ,  $c = 32.35 \text{ \AA}$ ,  $\alpha = \beta = 90^\circ$ , and  $\gamma = 120^\circ$  which agrees well with JCPDS card no. 00-032-0456.  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures possess a cubic structure of the unit cell with lattice parameters  $a = b = c = 10.8 \text{ \AA}$ , and  $\alpha = \beta = \gamma = 90^\circ$  which agrees well with JCPDS card no. 00-032-0456.  $\text{In}_2\text{Se}_3$  nanostructures possess a hexagonal structure of the unit cell with lattice parameters  $a = b = 7.05 \text{ \AA}$ ,  $c = 19.88 \text{ \AA}$ ,  $\alpha = \beta = 90^\circ$ , and  $\gamma = 120^\circ$ , which agrees well with JCPDS card no. 00-032-0456.

### 3.3. Scanning electron microscopy (SEM)

The morphology of the  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  and  $\text{In}_2\text{Se}_3$  nanostructures is depicted in Fig. 4. Fig. 4(a) shows the FESEM image of  $\text{In}_2\text{S}_3$ , revealing the presence of nanostructures with an average size ranging from 700 nm to 2500 nm. The size distribution of the nanostructures is displayed in Fig. 4(b). Some of the nanostructures exhibit cubic shapes, as shown in the inset of Fig. 4(a). On the other hand, Fig. 4(c) displays the

FESEM image of  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , indicating the presence of nanostructures and nanoplates. The formation of  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures and nanoplates may be attributed to the combination of  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{Se}_3$  nanostructures, which is supported by the mixed phase observed in the XRD profile of  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ . The width of some nanoplates is around 1250 nm, as shown in the inset of Fig. 4(c). The size distribution of the nanoplates is depicted in Fig. 4(d). Furthermore, EDS mapping of  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures is shown in Fig. S2 (ESI<sup>†</sup>). In contrast, the FESEM image of  $\text{In}_2\text{Se}_3$  shows a nanofiber morphology as shown in Fig. 4(e). The length of a single nanofiber is approximately 3660 nm, and the width is around 139 nm. The average width distribution of the nanofibers is presented in Fig. 4(f). These nanofiber morphologies enhance the performance of the photodetector due to their large surface area. Additionally, the EDS mapping of the  $\text{In}_2\text{Se}_3$  nanofibers confirms the successful presence of indium and selenium elements within the nanofiber structure, as shown in Fig. 4(g).

### 3.4. Energy dispersive spectroscopy (EDS)

EDS is a reliable and effective technique for identifying elemental composition in nanostructures.<sup>59–62</sup> The EDS spectra of the as-synthesized nanostructures are shown in Fig. S3 (ESI<sup>†</sup>). Compared to the  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  and  $\text{In}_2\text{Se}_3$  nanostructures, the amount of In in the as-synthesized  $\text{In}_2\text{S}_3$  is slightly higher, according to the data analysis. In general, they are nearly stoichiometric. The absence of any other peaks in the spectra

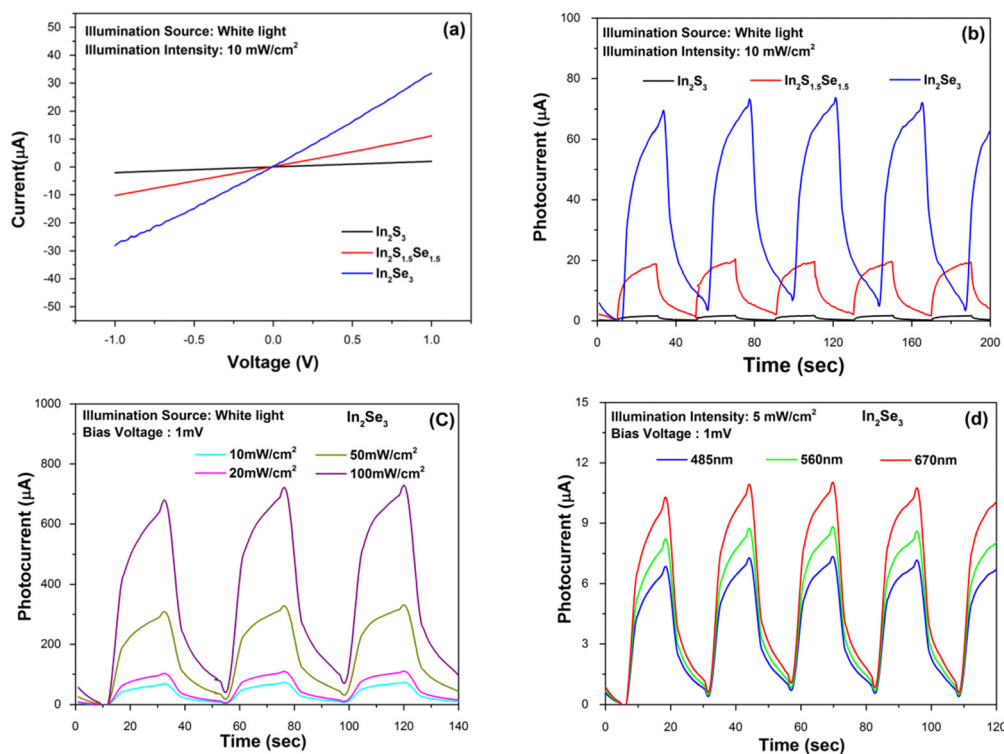

Fig. 5 The (a)  $I$ - $V$  characteristics, (b) pulse photoresponse of  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  nanostructures, (c) pulse photoresponse of  $\text{In}_2\text{Se}_3$  nanofibers at different illumination, and (d) pulse photoresponse of  $\text{In}_2\text{Se}_3$  nanofibers at different intensity.

**Table 1** The typical photoresponse parameters of the  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  nanostructures at 1 mV bias voltage and comparison with reported data

Sample	Illumination source	Intensity ( $\text{mW cm}^{-2}$ )	Photo current ( $\mu\text{A}$ )	Responsivity ( $\text{mA W}^{-1}$ )	Detectivity $\times 10^9$ (Jones)	EQE (%)	Rise time (s)	Decay time (s)
$\text{In}_2\text{S}_3$	White LED	10	2	5.3	1.45	—	5.9	6.7

is strong evidence that the synthesised nanostructures are chemically pure.

### 3.5. Photo detection application

To study the photo-detection applications of  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  and  $\text{In}_2\text{Se}_3$  nanostructures separately, a glass substrate is used and the channel is prepared by making thin and straight marks using a glass cutter. Then, the suspensions of  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  and  $\text{In}_2\text{Se}_3$  nanomaterials are drop-casted multiple times on a channel with continuous heating at 100 °C to remove the dispersing medium (distilled water). Two copper wires are bonded on the prepared samples using Ag paste. The prepared devices were further annealed at 120 °C for 5 h and used for photo-detection experiments. The various temporal detecting experiments are performed using a Keithley-4205 SMU.

First, as shown in Fig. 5(a), the current-voltage characteristics of the devices were measured. The  $I$ - $V$  curves for the devices are linear, indicating that the connections between the nanostructures and the Ag electrodes are ohmic. The current is found to increase as Se replaces S. In order to examine the transient photoresponse of the prepared devices, the light is turned on and off at regular intervals. At a bias voltage of 1 mV and under white light with a power intensity of 10  $\text{mW cm}^{-2}$ , the device's current is plotted as a function of time in Fig. 5(b). The devices had a consistent and reliable response to white light. Time constants are calculated for both the current rise ( $\tau_{\text{rise}}$  - the time needed for the current to increase by 90%) and decay ( $\tau_{\text{decay}}$  - the time needed for the current to decrease by 10%). In addition to these, the photocurrent ( $I_{\text{ph}} = I_{\text{ill}} - I_{\text{dark}}$ , where  $I_{\text{ill}}$  is the current under illumination and  $I_{\text{dark}}$  is the current in the dark) appears to be amplified from 2  $\mu\text{A}$  for pure  $\text{In}_2\text{S}_3$  to 70  $\mu\text{A}$  (35 times) for the  $\text{In}_2\text{Se}_3$  sample. The photo-response of the  $\text{In}_2\text{Se}_3$  nanofibers under different illumination intensity (10, 20, 50 and 100  $\text{mW cm}^{-2}$ ) is shown in Fig. 5(c). A detailed photodetection study of  $\text{In}_2\text{Se}_3$  device was carried out with different illumination sources. Fig. 5(d) shows the wavelength dependent pulse-photo response, examined at 485 nm, 560 nm and 670 nm light sources at intensity 5  $\text{mW cm}^{-2}$  and bias voltage 1 mV. The good response at 670 nm illumination is due to the maximum optical absorbance for the  $\text{In}_2\text{Se}_3$  nanofiber device.<sup>63</sup> In contrast, nanofibers have a larger surface area-to-volume ratio than nanostructures, which can enhance

the absorption of incident light and increase the number of charge carriers generated. This can lead to a higher photocurrent and sensitivity in photodetection. The detector parameters utilised in the quantitative study, including photo-responsivity, detectivity, EQE (%), rise time, and decay time at specific conditions are listed in Table 1. They are evaluated using standard equations reported by Zhou J *et al.*<sup>50</sup> A comparison of the reported photodetection parameters is provided in Table 1.

1D  $\text{In}_2\text{Se}_3$  nanofibers are likely to have a higher photo-detector response compared to  $\text{In}_2\text{S}_3$  and  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$  nanostructures due to their unique properties. One possible reason for this higher response is the morphology of the nanofibers. Nanofibers have a high surface area to volume ratio, which can increase the interaction between the material and the incident light, leading to a higher photodetector response. Another factor is the electronic properties of  $\text{In}_2\text{Se}_3$ .  $\text{In}_2\text{Se}_3$  has a narrow bandgap, which means that it can absorb a wide range of wavelengths of light, making it a good candidate for photo-detection. Additionally,  $\text{In}_2\text{Se}_3$  has high carrier mobility and a long carrier lifetime, which can enhance the efficiency of charge separation and transport, leading to a higher photo-detector response.

The photodetector properties of 1D  $\text{In}_2\text{Se}_3$  nanofibers are studied through detectivity and responsivity. The results show that the nanofibers exhibit a detectivity of  $22.6 \times 10^9$  Jones. These detectivities are higher than those of other Se-based materials such as 2D layered  $\text{Ta}_2\text{NiSe}_5$ ,<sup>66</sup>  $\text{PdSe}_2$  flakes,<sup>67</sup>  $\text{SnS}_2/\text{InSe}$  heterostructures,<sup>68</sup>  $\text{ZrSe}_3$ ,<sup>69</sup> and  $\text{PANI}/\text{ZnO}$ .<sup>70</sup> These findings suggest that 1D  $\text{In}_2\text{Se}_3$  holds promise as a material for utilization in photodetector devices.

## 4. Conclusion

The hydrothermal method was successfully employed to deposit nanomaterials of  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  onto glass substrates. A study was conducted to investigate the effects of semiconductors  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  on their structural, morphological, compositional, electrical and photodetector properties. The presence of constituent elements in the  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  was confirmed through EDS and XPS studies. The responsivity values of the  $\text{In}_2\text{S}_3$ ,  $\text{In}_2\text{S}_{1.5}\text{Se}_{1.5}$ , and  $\text{In}_2\text{Se}_3$  photodetectors were approximately

5.31, 47.7, and 185.8 mA W<sup>-1</sup>, respectively. The highest detectivity of  $23.3 \times 10^9$  Jones was obtained in the In<sub>2</sub>Se<sub>3</sub> sample. The photodetectors exhibited very short response times, ranging from 5 to 8.8 seconds. The higher photodetector response of the 1D In<sub>2</sub>Se<sub>3</sub> nanofibers compared to In<sub>2</sub>S<sub>3</sub> and In<sub>2</sub>S<sub>1.5</sub>Se<sub>1.5</sub> nanostructures may be due to their larger surface area-to-volume ratio, crystal structure, and composition, and the dimensions of the nanofibers. These findings suggest that In<sub>2</sub>Se<sub>3</sub> nanofibers have potential applications in visible-light selective photo-sensing devices.

## Data availability

Data will be provided upon request.

## Conflicts of interest

There is no conflict of interest for any author.

## Acknowledgements

The authors wish to acknowledge the National Dong Hwa University, Department of Physics, Hualien 97401, Taiwan, for generously offering the necessary facilities and resources for conducting this study. Furthermore, the authors would like to extend their appreciation to Sardar Patel University P.G, Department of Physics, Vallabh Vidyanagar - 388120, Gujarat, India, for providing the essential facilities and resources for the successful completion of this work.
