# A systematic study of $\text{TMO}_n$ (TM = V, Cr, Mn, and Fe; $n = 3$ and 6) clusters embedded in a $\text{PtS}_2$ monolayer†

Nguyen Thanh Tien,<sup>a</sup> J. Guerrero-Sanchez<sup>b</sup> and D. M. Hoat<sup>a,c,d</sup>

Doping-based magnetism engineering is an effective approach to synthesize new multifunctional two-dimensional (2D) materials from their non-magnetic counterparts. In this work, doping with  $\text{TMO}_n$  clusters (TM = V, Cr, Mn, and Fe;  $n = 3$  and 6) is proposed to induce feature-rich electronic and magnetic properties in a  $\text{PtS}_2$  monolayer. The pristine monolayer is a non-magnetic semiconductor with an indirect energy gap of 1.81 (2.67) eV as obtained from PBE(HSE06)-based calculations.  $\text{PtS}_3$ -type multivacancies magnetize significantly the monolayer, inducing the emergence of half-metallicity. In this case, a total magnetic moment of 1.90  $\mu_B$  is obtained and magnetic properties are produced mainly by atoms around the vacancy sites. Meanwhile, the  $\text{PtS}_2$  monolayer is metallized by creating  $\text{PtS}_6$ -type multivacancies without magnetization. Depending on the type of  $\text{TMO}_n$  cluster, either a feature-rich diluted magnetic semiconductor or half-metallic nature is induced, which is regulated mainly by the incorporated clusters. Except for the  $\text{FeO}_6$  cluster, TM atoms and O atoms exhibit an antiparallel spin orientation, resulting in total magnetic moments between 1.00 and 4.00  $\mu_B$ . Meanwhile, the parallel spin ordering gives a large total magnetic moment of 5.99  $\mu_B$  for the  $\text{FeO}_6$ -doped monolayer. Furthermore, Bader charge analysis indicates that all the clusters attract charge from the host monolayer that is mainly due to the electronegative O atoms. Our results may introduce cluster doping as an efficient way to create new spintronic 2D materials from a non-magnetic  $\text{PtS}_2$  monolayer.

## 1 Introduction

Two-dimensional (2D) magnetic materials have sparked special interest because of their importance for fundamental research as well as technological applications in the spintronic field.<sup>1,2</sup> In particular, intrinsic ferromagnetism has been found in  $\text{CrI}_3$  (ref. 3) and  $\text{Gr}_2\text{Ge}_2\text{Te}_6$  (ref. 4) nanosheets, and few-layer  $\text{Fe}_3\text{GeTe}_2$ .<sup>5</sup> These findings open the way for the future development of diminutive spintronic devices based on 2D materials. Note that the mentioned materials contain transition metals as constituent atoms, which produce mainly their intrinsic magnetism. Meanwhile, most of the 2D materials discovered until now lack inherent magnetism. Therefore, researchers have made extensive efforts to introduce magnetism into these non-magnetic counterparts. In this regard, various strategies have been

proposed encompassing defect engineering,<sup>6–8</sup> doping,<sup>9–11</sup> surface modification,<sup>12–14</sup> and edge cutting to form nanoribbons.<sup>15–17</sup> Among them, substitutional doping has been widely employed as a simple and effective technique for inducing magnetization in 2D materials, validated by both theoretical and experimental investigations. Experimentally, doping processes have been successfully realized by either ion implantation<sup>18,19</sup> or chemical vapor deposition.<sup>20,21</sup> Theoretically, first-principles calculations have demonstrated that not only transition metals<sup>22,23</sup> but also non-transition metals or even non-metals impurities can induce significant magnetism in non-magnetic 2D materials.<sup>24–27</sup>

On the other hand, 2D layered transition metal dichalcogenides (TMDs) have been widely explored due to their potential for electronic and optoelectronic applications.<sup>28,29</sup> Unlike the semimetal behavior of graphene, TMD monolayers are semiconductors with sizable electronic band gaps between 1 and 3 eV. Initially, research was focused on those TMDs based on the VIB group (Mo and W atoms), which have been synthesized by both top-down (exfoliation from their bulk counterparts) and bottom-up (Chemical Vapor Deposition – CVD) methods.<sup>30–33</sup> Recently, as new members of the 2D TMD family, noble metal dichalcogenides have drawn great research attention as promising candidates for different applications including optoelectronics,<sup>34</sup> mid-infrared photonics,<sup>35</sup> and photocatalysis,<sup>36</sup>

<sup>a</sup>College of Natural Sciences, Can Tho University, 3-2 Road, Can Tho City 900000, Vietnam<sup>b</sup>Universidad Nacional Autónoma de México, Centro de Nanociencias y Nanotecnología, Apartado Postal 14, Código Postal 22800, Ensenada, Baja California, Mexico<sup>c</sup>Institute of Theoretical and Applied Research, Duy Tan University, Ha Noi 100000, Vietnam. E-mail: dominhhoat@duytan.edu.vn<sup>d</sup>Faculty of Natural Sciences, Duy Tan University, Da Nang 550000, Vietnam† Electronic supplementary information (ESI) available. See DOI: <https://doi.org/10.1039/d4na00465e>

among others. Among them, platinum sulfide (PtS<sub>2</sub>) has been investigated both experimentally and theoretically. Large-scale few-layer PtS<sub>2</sub> films have been synthesized by Zhao *et al.*<sup>37</sup> by means of the direct sulfurization of pre-deposited Pt. The synthesized materials exhibit p-type transport behavior with uniform electrical performance. Similarly, Lu *et al.*<sup>38</sup> have also realized the synthesis of large-scale uniform few-layer PtS<sub>2</sub> in a plasma enhanced CVD furnace, where a field-effect transistor (FET) fabricated on few-layer PtS<sub>2</sub> shows a p-type semiconductor behavior. Using first-principles calculations, Villaos *et al.*<sup>39</sup> have demonstrated that the PtS<sub>2</sub> band gap increases according to reduce its thickness, from 0.25 eV of bulk counterpart to 1.68 eV of monolayer counterpart. Moreover, several research groups have studied the modification of PtS<sub>2</sub> monolayer electronic and magnetic properties using external strain<sup>40</sup> and vacancies.<sup>41</sup>

It is well known that doping is an efficient way to change the physical properties of 2D materials.<sup>42</sup> Beyond monoelement substitution, doping with multielement impurities has also been proposed to tailor charge and magnetic states. For example, feature-rich electronic and magnetic properties can be induced in a MoS<sub>2</sub> monolayer by doping with transition metal trioxides – TMO<sub>3</sub> (TM = 3d transition metals)<sup>43</sup> or FeX<sub>6</sub> clusters (X = S, C, N, O, F).<sup>44</sup> Similarly, magnetic functionalization of graphene is also achieved by doping with TMO<sub>3</sub> clusters to form new promising spintronic 2D materials.<sup>45</sup> Motivated by these findings, we investigate the effects of transition metal oxide TMO<sub>*n*</sub> (TM = V, Cr, Mn, and Fe; *n* = 3 and 6) clusters on the PtS<sub>2</sub> monolayer electronic and magnetic properties. The modified electronic properties are studied using the spin-polarized band structure and density of states, while the difference in spin-dependent charge distributions confirms the induced magnetism. It is anticipated that our results indicate the emergence of novel feature-rich electronic and magnetic properties in the PtS<sub>2</sub> monolayer by doping with TMO<sub>*n*</sub> clusters towards creating potential spintronic 2D materials.

## 2 Computational details

Density Functional Theory (DFT)-based calculations<sup>46</sup> are performed using the Vienna *ab initio* Simulation Package (VASP),<sup>47,48</sup> which makes use of the Projector Augmented Wave (PAW) method. Electron exchange-correlation potential is treated using the Perdew–Burke–Ernzerhof scheme of the Generalized Gradient Approximation (GGA-PBE).<sup>49</sup> In combination with the DFT + U method reported by Dudarev *et al.*,<sup>50</sup> the finite on-site Coulomb interactions of highly correlated 3d electrons of transition metals are considered using effective Hubbard parameters  $U_{\text{eff}}$  of 3.25, 3.70, 3.90, and 5.40 eV for V, Cr, Mn, and Fe atoms,<sup>51,52</sup> respectively. For the expansion of the basis set, the cutoff energy is chosen as 500 eV. For self-consistent iterations, the total energy is set to converge to  $1 \times 10^{-6}$  eV. The structures are relaxed until the forces on each atom have converged to  $1 \times 10^{-2}$  eV Å<sup>-1</sup>. A vacuum layer wider than 14 Å – perpendicular to the monolayer plane – is inserted (along the z-axis) to ensure the negligible interactions between periodic images.

In order to investigate the effects of vacancies and doping with clusters in the PtS<sub>2</sub> monolayer, a  $4 \times 4 \times 1$  supercell with 48 atoms is constructed. Herein, the Brillouin zone is sampled with a  $4 \times 4 \times 1$   $\Gamma$ -centered Monkhorst–Pack *k*-mesh.<sup>53</sup> Meanwhile, a denser *k*-mesh of  $20 \times 20 \times 1$  is utilized for the pristine monolayer with 3 atoms in the unit cell. Then, the formation energy  $E_f$  is calculated as follows:

$$E_f = E_t - E_m + \sum_i n_i \mu_i - \sum_j n_j \mu_j \quad (1)$$

where  $E_t$  and  $E_m$  are the total energy of the defected/doped and pristine PtS<sub>2</sub> monolayers, respectively;  $n$  and  $\mu$  denote the number of replaced host atoms (*i*)/incorporated atoms (*j*) and their chemical potential, respectively. In addition, the cohesive energy  $E_c$  of each system is also computed using the following expression:

$$E_c = \frac{E_t - [m_{\text{Pt}}E(\text{Pt}) + m_{\text{S}}E(\text{S}) + m_{\text{TM}}E(\text{TM}) + m_{\text{O}}E(\text{O})]}{m_{\text{Pt}} + m_{\text{S}} + m_{\text{TM}} + m_{\text{O}}} \quad (2)$$

Herein,  $m_x$  is the number of atoms X in the system;  $E(X)$  refers to the energy of an isolated X atom.

The electronic interactions between the host monolayer and clusters are investigated by means of Bader charge analysis,<sup>54,55</sup> which provides information about the charge transfer. In addition, the charge density difference  $\Delta\rho$  is obtained from cleaving separately the host monolayer and cluster from the doped systems as follows:

$$\Delta\rho = \rho(\text{TMO}_x + \text{PtS}_2) - \rho(\text{PtS}_2) - \rho(\text{TMO}_x) \quad (3)$$

In this equation, the terms on the right hand side denote the charge density of the doped system, the charge density of the host monolayer, and the charge density of the cluster, respectively.

## 3 Results and discussion

### 3.1 Pristine PtS<sub>2</sub> monolayer

As a first step, the PtS<sub>2</sub> monolayer geometry is optimized. Fig. 1 shows the optimized unit cell, which is fully described by the following structural parameters: (1) lattice constant  $a = 3.57$  Å, which is in good agreement with previous calculations;<sup>56</sup> (2) chemical bond length  $d_{\text{Pt-S}} = 2.40$  Å; (3) total buckling height  $\Delta_{\text{total}} = 2 \times \Delta_{\text{Pt-S}} = 2 \times 1.23 = 2.46$  Å; (4) interatomic angles  $\angle \text{PtSpt} = 96.20^\circ$  and  $\angle \text{SPts} = 83.80^\circ$ . Then, the stability of the PtS<sub>2</sub> monolayer is examined using the following criteria:

- The phonon dispersion curves are calculated using the PHONOPY code.<sup>57</sup> The results plotted in Fig. 2a show no obvious nonphysical imaginary frequency in the entire Brillouin zone, indicating that the PtS<sub>2</sub> monolayer is dynamically stable.

- *Ab initio* Molecular Dynamics (AIMD) simulations are performed at 300 K for 5 ps, using a  $4 \times 4 \times 1$  supercell. Herein, the NVT ensemble and Nose–Hoover thermostat are utilized.<sup>58,59</sup> Fig. 2b shows the variation of temperature and the final atomic structure. The stable fluctuation of temperature around 300 K can be noted. Moreover, no geometry reconstruction or broken

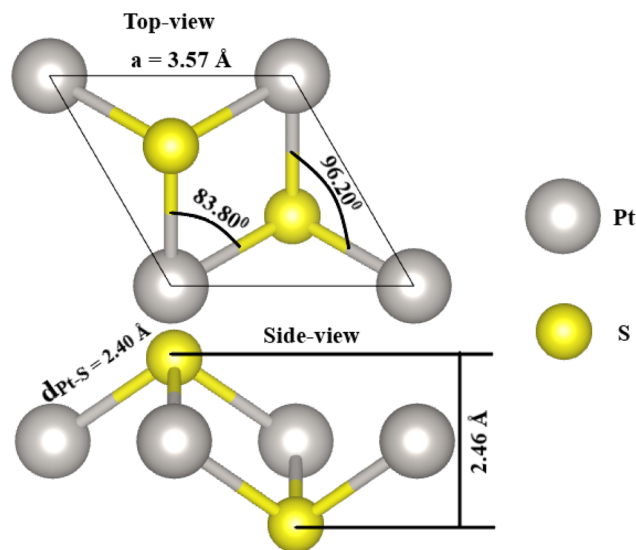

Fig. 1 Optimized unit cell of the PtS<sub>2</sub> monolayer.

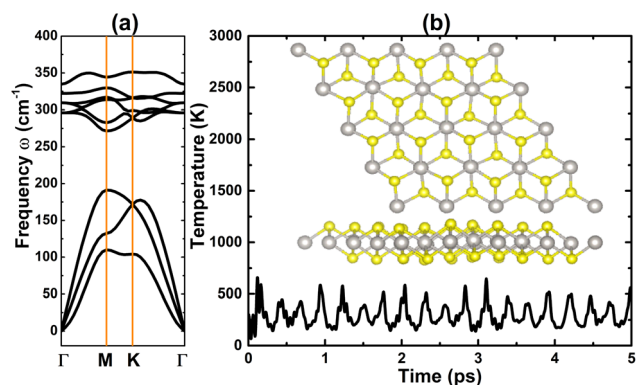

Fig. 2 (a) Phonon dispersion curves and (b) AIMD simulations (variation of temperature + final atomic structure) at 300 K of the PtS<sub>2</sub> monolayer.

Pt–S chemical bonds are noted, indicating that the structure is well preserved. These results indicate that the PtS<sub>2</sub> monolayer is thermally stable.

- Using the energy-strain method, the elastic constants of the PtS<sub>2</sub> monolayer are calculated. According to our calculations, its  $C_{11}$  and  $C_{12}$  constants have values of 88.57 and 23.26 N m<sup>-1</sup>, respectively, which can describe well the elasticity of 2D hexagonal symmetry. Importantly, the obtained elastic constants satisfy Born's criteria:<sup>60</sup>  $C_{11} > 0$  and  $C_{11} > |C_{12}|$ , indicating that the PtS<sub>2</sub> monolayer is mechanically stable.

The electronic properties as well as interactions between the Pt and S atoms of the PtS<sub>2</sub> monolayer are investigated using the optimized atomic structure. Fig. 3a shows the band structures obtained from PBE- and HSE06-based calculations. The HSE06 functional with a 25% fraction of the exact Hartree exchange potential is also utilized to calculate more accurately the monolayer band gap.<sup>61</sup> Since the valence band maximum and conduction band minimum are located at different points as determined by both functionals, the PtS<sub>2</sub> monolayer can be

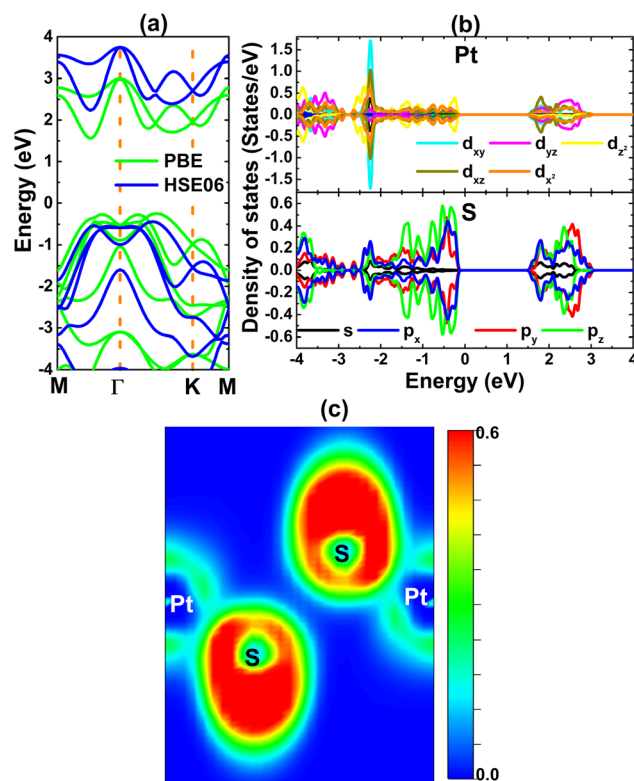

Fig. 3 (a) Electronic band structure (the Fermi level is set to 0 eV), (b) projected density of states, and (c) electron localization function of the PtS<sub>2</sub> monolayer.

classified as a 2D indirect-gap semiconductor. The standard PBE functional provides an energy gap of 1.81 eV, while a larger (expected to be more accurate) value of 2.67 eV is obtained from HSE06-based computation. Note that these energy gaps are in line with results reported previously by several research groups,<sup>39,62</sup> suggesting the reliability of our calculations. The projected density of states (PDOS) of both Pt and S atoms is given in Fig. 3b to analyze their contribution. Significant contributions of Pt-5d and S-3p orbitals in the considered energy range around the Fermi level can be noted. Moreover, their electronic states exhibit significant hybridization in both the valence band and the conduction band, giving evidence of the covalent Pt–S chemical bond. However, the difference in electronegativity between Pt and S atoms may cause charge transfer, forming ionic bonds. Specifically, Bader charge analysis implies that each S atom attracts a charge of 0.21 e from the Pt atom. Therefore, it can be concluded that the Pt–S chemical bonds in the PtS<sub>2</sub> monolayer exhibit a mix of ionic and covalent characteristics.

### 3.2 Effects of PtS<sub>3</sub>- and PtS<sub>6</sub>-type multivacancies

In this part, the effects of PtS<sub>3</sub>- and PtS<sub>6</sub>-type multivacancies (Va<sub>PtS<sub>3</sub></sub> and Va<sub>PtS<sub>6</sub></sub> systems) on the PtS<sub>2</sub> monolayer electronic and magnetic properties are investigated. The atomic structures of these defected systems are visualized in Fig. S1 of the ESI.† Table 1 shows  $E_f$  values of 7.38 and 12.64 eV for Va<sub>PtS<sub>3</sub></sub> and Va<sub>PtS<sub>6</sub></sub> systems, respectively. These values correspond to 1.85 and 1.81 eV per atom for each single vacancy, respectively. The PtS<sub>2</sub>

**Table 1** Formation energy  $E_f$  (eV), cohesive energy  $E_c$  (eV per atom), electronic band gap  $E_g$  (eV; spin-up/spin-down; M: metallic), charge transferred from the host monolayer to the cluster  $\Delta Q$  (e), total magnetic moment  $M_t$  ( $\mu_B$ ), and local magnetic moment  $M_l$  of the cluster ( $\mu_B$ , TM/O) of the defected/doped PtS<sub>2</sub> monolayer

	$E_f$	$E_c$	$E_g$	$\Delta Q$	$M_t$	$M_l$
Va <sub>PtS<sub>3</sub></sub>	7.38	-4.41	M/0.42	—	1.90	—
Va <sub>PtS<sub>6</sub></sub>	12.64	-4.37	M/M	—	0.00	—
D <sub>VO<sub>3</sub></sub>	-2.06	-4.53	M/1.27	0.76	1.00	0.83/-0.08
D <sub>CrO<sub>3</sub></sub>	-1.52	-4.45	0.83/1.25	0.85	2.00	2.37/-0.13
D <sub>MnO<sub>3</sub></sub>	-1.36	-4.47	0.80/1.17	1.07	3.00	3.80/-0.08
D <sub>FeO<sub>3</sub></sub>	-0.36	-4.49	M/1.16	1.07	4.00	3.92/0.02
D <sub>VO<sub>6</sub></sub>	-3.41	-4.57	1.23/1.49	2.99	1.00	1.12/-0.03
D <sub>CrO<sub>6</sub></sub>	-2.81	-4.49	M/1.51	3.17	2.00	2.79/-0.11
D <sub>MnO<sub>6</sub></sub>	-1.81	-4.49	1.52/0.82	3.03	3.00	3.76/-0.14
D <sub>FeO<sub>6</sub></sub>	-1.05	-4.52	1.52/0.09	3.06	5.99	4.27/0.20

monolayer exhibits good structural and chemical stability under the effects of multivacancies, which is confirmed by negative  $E_c$  values of -4.41 and -4.37 eV per atom, respectively. However, these values are less negative than that of the perfect PtS<sub>2</sub> monolayer (-4.53 eV per atom), suggesting a slight reduction in the stability.

Significant magnetization of the PtS<sub>2</sub> monolayer induced by creating PtS<sub>3</sub>-type multivacancies is found. The emergence of magnetism is confirmed by the difference in charge distribution between spin channels. Specifically, this difference leads to a total magnetic moment of 1.90  $\mu_B$ . The spin density illustrated in Fig. 4 indicates that the magnetic properties of the Va<sub>PtS<sub>3</sub></sub> system are produced mainly by first S atoms from vacancy sites, where a small contribution from second Pt atoms and third S atoms is also observed. In contrast, no magnetism is obtained for the Va<sub>PtS<sub>6</sub></sub> system, indicating the preservation of the non-magnetic nature of the PtS<sub>2</sub> monolayer when creating PtS<sub>6</sub>-type nanoholes.

Fig. 5 shows the spin-polarized band structures of Va<sub>PtS<sub>3</sub></sub> and Va<sub>PtS<sub>6</sub></sub> systems. From the figure, one can see new middle-gap

**Fig. 4** Spin density (iso-surface value: 0.005 e  $\text{\AA}^{-3}$ ) in the PtS<sub>2</sub> monolayer with PtS<sub>3</sub>-type vacancies.

**Fig. 5** Spin-polarized band structure (the Fermi level is set to 0 eV) of the PtS<sub>2</sub> monolayer with (a) PtS<sub>3</sub>- and (b) PtS<sub>6</sub>-type vacancies.

energy states created by vacancy defects that determine the system electronic behavior. It is important to mention that the unbalanced charge distribution is also reflected in the spin polarization of the Va<sub>PtS<sub>3</sub></sub> system band structure, while that of the Va<sub>PtS<sub>6</sub></sub> system is totally symmetric. These profiles are in agreement with the above analysis of magnetism. One of the PtS<sub>2</sub> monolayer spin states is metallized under the effects of PtS<sub>3</sub>-type multivacancies, while the semiconductor character is preserved in the other one. Therefore, the Va<sub>PtS<sub>3</sub></sub> system can be classified as a 2D half-metallic material. Thus, creating PtS<sub>3</sub>-type multivacancies is an effective method to functionalize PtS<sub>2</sub> monolayers for spintronic applications.<sup>63</sup> In contrast, the Va<sub>PtS<sub>6</sub></sub> system exhibits a non-magnetic metallic nature considering the metallization of both spin states.

The origin of middle-gap states is studied through the PDOS spectra of Pt and S atoms closest to vacancy sites. From Fig. 6a, one can see that the spin-up metallic character of the Va<sub>PtS<sub>3</sub></sub> system is generated mainly by Pt- $d_{xy}$ , Pt- $d_{yz}$ , and S- $p_z$  states. The spin-down band gap is regulated by the hybridization between Pt- $d_{xz}$  and S- $p_z$  states, which also produces the system magnetism as suggested by their strong spin polarization in the vicinity of the Fermi level. In the case of the Va<sub>PtS<sub>6</sub></sub> system, Pt- $d_{yz}$  and S- $p_z$  states cause mainly monolayer metallization (see Fig. 6b).

**Fig. 6** Projected density of states of atomic species around the defect sites of the PtS<sub>2</sub> monolayer with (a) PtS<sub>3</sub>- and (b) PtS<sub>6</sub>-type vacancies.

### 3.3 Effects of doping with TMO<sub>3</sub> clusters

Herein, the effects of doping with TMO<sub>3</sub> (D<sub>TMO<sub>3</sub></sub> system) clusters on the PtS<sub>2</sub> monolayer electronic and magnetic properties are investigated. The calculated formation energy and cohesive energy are given in Table 1. Our calculations provide negative  $E_f$  values of  $-2.06$ ,  $-1.52$ ,  $-1.36$ , and  $-0.36$  eV for D<sub>VO<sub>3</sub></sub>, D<sub>CrO<sub>3</sub></sub>, D<sub>MnO<sub>3</sub></sub>, and D<sub>FeO<sub>3</sub></sub> systems, respectively. These results indicate the exothermic character of the doping process. The doping process is less favorable according to the increase of the atomic number of transition metals since the formation energy becomes less negative in this direction. Moreover, negative  $E_c$  values between  $-4.53$  and  $-4.45$  eV per atom imply that all four D<sub>TMO<sub>3</sub></sub> systems are structurally and chemically stable, where the incorporation of clusters reduces only slightly the monolayer stability.

Our calculations confirm the significant magnetization of the PtS<sub>2</sub> monolayer upon doping with TMO clusters. Total magnetic moments of 1.00, 2.00, 3.00, and 4.00  $\mu_B$  are obtained for D<sub>VO<sub>3</sub></sub>, D<sub>CrO<sub>3</sub></sub>, D<sub>MnO<sub>3</sub></sub>, and D<sub>FeO<sub>3</sub></sub> systems, respectively. As expected, the system magnetism is produced mainly by TM atoms as suggested by the illustration of spin density in Fig. 7. From the figure, one can see large spin surfaces centered at TM sites. Moreover, small iso-surfaces are also observed near O and S atoms, indicating their small contribution to the system magnetism. It is important to note the antiparallel spin orientation between TM atoms and their neighboring O and S atoms.

The magnetism of D<sub>TMO<sub>3</sub></sub> systems is also reflected in the spin polarization as observed in their band structures displayed in Fig. 8. The electronic nature of the doped systems is determined by doping-induced middle-gap energy states. Specifically, D<sub>VO<sub>3</sub></sub> and D<sub>FeO<sub>3</sub></sub> are half-metallic 2D systems considering their metallic spin-up state and semiconductor spin-down state. Herein, the spin-down energy gaps of 1.27 and 1.16 eV are obtained, respectively. Additionally, a diluted magnetic semiconductor nature emerges in the PtS<sub>2</sub> monolayer when doping with CrO<sub>3</sub> and MnO<sub>3</sub> clusters. In these cases, the spin-up/spin-down band gaps of 0.83/1.25 and 0.80/1.17 eV are obtained for D<sub>CrO<sub>3</sub></sub> and D<sub>MnO<sub>3</sub></sub> systems, respectively. These results suggest that feature-rich electronic and magnetic properties desired for spintronic applications can be induced in the PtS<sub>2</sub> monolayer by doping with TMO<sub>3</sub> clusters.<sup>64</sup>

The calculated charge density difference confirms the charge depletion at TM atoms and charge accumulation at their neighboring O and S atoms (see Fig. S2 of the ESI†). The Bader charge is analyzed focusing on the constituent atoms of clusters. It is found that V, Cr, Mn, and Fe atoms lose charge amounts of 1.76, 1.61, 1.45, and 1.42 e, respectively. Meanwhile, each O atom of VO<sub>3</sub>, CrO<sub>3</sub>, MnO<sub>3</sub>, and FeO<sub>3</sub> clusters gains a charge of 0.84, 0.82, 0.84, and 0.83 e, respectively. Therefore, it can be concluded that the host monolayer loses charge, transferring 0.76, 0.85, 1.07, and 1.07 e to VO<sub>3</sub>, CrO<sub>3</sub>, MnO<sub>3</sub>, and FeO<sub>3</sub> clusters, respectively.

Fig. 9 shows the PDOS spectra of TM and O atoms of the clusters to study their contribution in the vicinity of the Fermi level, where TM-3d and O-2p orbitals are most prominent. Note that TM- $d_{xy}$  -  $d_{yz}$  -  $d_z^2$  and P- $p_z$  states primarily contribute to

Fig. 7 Spin density (iso-surface value:  $0.005 \text{ e } \text{\AA}^{-3}$ ; red surface: positive spin value; green surface: negative spin value) in the PtS<sub>2</sub> monolayer doped with (a) VO<sub>3</sub>, (b) CrO<sub>3</sub>, (c) MnO<sub>3</sub>, and (d) FeO<sub>3</sub> clusters.

the metallic character of the spin-up state in the D<sub>VO<sub>3</sub></sub> and D<sub>FeO<sub>3</sub></sub> systems. As expected, the 3d orbital of transition metals exhibits strong spin polarization around the Fermi level to confirm their key role in producing the system magnetism.

### 3.4 Effects of doping with TMO<sub>6</sub> clusters

Now, the effects of doping with TMO<sub>6</sub> (D<sub>TMO<sub>6</sub></sub> system) clusters on the PtS<sub>2</sub> monolayer electronic and magnetic properties are investigated. Similar to previous cases of doping with TMO<sub>3</sub> clusters, negative  $E_f$  values suggest an exothermic doping process. Specifically,  $E_f$  values of  $-3.41$ ,  $-2.81$ ,  $-1.81$ , and  $-1.05$  eV are obtained for D<sub>VO<sub>6</sub></sub>, D<sub>CrO<sub>6</sub></sub>, D<sub>MnO<sub>6</sub></sub>, and D<sub>FeO<sub>6</sub></sub> systems, respectively. Note that the formation energy becomes less negative when switching the transition metal from V to Fe, indicating the reduction of energetic favorability in this direction. Once formed, all the doped systems may have good structural and chemical stability as suggested by negative  $E_c$  values between  $-4.57$  and  $-4.49$  eV per atom, which are quite similar to that of the bare PtS<sub>2</sub> monolayer.

Fig. 8 Spin-polarized band structure (the Fermi level is set to 0 eV) of the PtS<sub>2</sub> monolayer doped with (a) VO<sub>3</sub>, (b) CrO<sub>3</sub>, (c) MnO<sub>3</sub>, and (d) FeO<sub>3</sub> clusters.

Fig. 9 Projected density of states of cluster atomic species of the PtS<sub>2</sub> monolayer doped with (a) VO<sub>3</sub>, (b) CrO<sub>3</sub>, (c) MnO<sub>3</sub>, and (d) FeO<sub>3</sub> clusters.

By calculating the difference in charge distribution between spin configurations, total magnetic moments of 1.00, 2.00, 3.00, and 5.99  $\mu_B$  are obtained for D<sub>VO<sub>6</sub></sub>, D<sub>CrO<sub>6</sub></sub>, D<sub>MnO<sub>6</sub></sub>, and D<sub>FeO<sub>6</sub></sub> systems, respectively. Fig. 10 illustrates the spin density in these cluster-doped systems, which confirms that magnetic properties are produced mainly by the incorporated clusters. The iso-surface size indicates the key role of transition metals, where a smaller contribution from O atoms is also noted. Note that TM atoms and O atoms in D<sub>VO<sub>6</sub></sub>, D<sub>CrO<sub>6</sub></sub> and D<sub>MnO<sub>6</sub></sub> systems exhibit an antiparallel spin orientation. In contrast, parallel spin ordering is observed for Fe atoms and O atoms in the D<sub>FeO<sub>6</sub></sub> system, resulting in a total magnetic moment that is much larger than that of the remaining three systems.

According to the emergence of the magnetism in the PtS<sub>2</sub> monolayer, doping with TMO<sub>6</sub> clusters leads to strong spin polarization in the electronic band structures as displayed in Fig. 11. Note that the spin symmetry breaking takes place mainly in the vicinity of the Fermi level of D<sub>TMO<sub>6</sub></sub> systems, where new middle-gap energy branches regulate their system

Fig. 10 Spin density (iso-surface value: 0.005 e  $\text{\AA}^{-3}$ ; red surface: positive spin value; green surface: negative spin value) in the PtS<sub>2</sub> monolayer doped with (a) VO<sub>6</sub>, (b) CrO<sub>6</sub>, (c) MnO<sub>6</sub>, and (d) FeO<sub>6</sub> clusters.

electronic nature. The band structure profiles imply the diluted magnetic semiconductor nature of  $D_{VO_6}$ ,  $D_{MnO_6}$  and  $D_{FeO_6}$  systems. In these cases, spin-up/spin-down energy gaps of 1.23/1.49, 1.52/0.82, and 1.52/0.09 eV are obtained, respectively. Moreover, the feature-rich half-metallicity is achieved by doping with  $CrO_6$  clusters, where the  $D_{CrO_6}$  system has a metallic spin-up state and a semiconductor spin-down state with an energy gap of 1.51 eV. Such diluted magnetic semiconductor and half-metallic characteristics make  $D_{TMO_6}$  systems prospective 2D candidates for spintronic applications.<sup>64</sup>

To investigate the interactions between clusters and their environment, the charge density difference is calculated. Charge depletion at TM sites and those Pt atoms around clusters is found, while charge enrichment is noted at O sites (see Fig. S3 of the ESI†). This feature indicates the charge gaining of O atoms, which is because of their more electronegative nature as compared to TM and Pt atoms. Focusing on the clusters, our Bader charge analysis indicates that the TM/O atoms of  $VO_6$ ,  $CrO_6$ ,  $MnO_6$ , and  $FeO_6$  cluster have an effective ionic charge of +1.93/−0.82, +1.63/−0.80, +1.71/−0.79, and +1.74/−0.80 e (“+”: charge losing; “−”: charge gaining), respectively. The results indicate that these clusters gain a charge of −2.99, −3.17, −3.03, and −3.06 e from the host  $PtS_2$  monolayer, respectively.

Fig. 12 Projected density of states of cluster atomic species of the  $PtS_2$  monolayer doped with (a)  $VO_6$ , (b)  $CrO_6$ , (c)  $MnO_6$ , and (d)  $FeO_6$  clusters.

The PDOS spectra of TM and O atoms are given in Fig. 12. In the considered energy range, TM-3d and O-2p orbitals make the main contributions. The metallic character of the  $D_{CrO_6}$  system spin-up state is derived mainly from the O- $p_z$  state. The degree of spin polarization also indicates the key role of TM atoms in producing magnetic properties, with additional contributions coming from the  $p_z$  state of their neighboring O atoms.

## 4 Conclusions

In summary, the effects of doping with  $TMO_n$  clusters on the electronic and magnetic properties of  $PtS_2$  monolayers have been systematically investigated using first-principles calculations. The dynamical, thermal, and mechanical stability of the  $PtS_2$  monolayer is confirmed. It is a 2D indirect-gap semiconductor material, whose Pt-S chemical bonds exhibit a mix of covalent and ionic characteristics. The non-magnetic nature is preserved by creating  $PtS_6$ -type multivacancies, where the monolayer becomes a metallic 2D material. In contrast, significant magnetism is achieved under the effects of  $PtS_3$ -type multivacancies, where the  $p_z$  state of S atoms around the vacancy sites is primarily responsible for magnetic properties. Interestingly, feature-rich half-metallicity is obtained for the  $Va_{PtS_3}$  system. Similarly, the monolayer is significantly magnetized by doping with  $TMO_n$  clusters. Feature-rich diluted magnetic semiconductor or half-metallic behaviors are obtained, depending on the nature of  $TMO_n$  clusters. In these cases, electronic and magnetic properties are regulated mainly by TM-3d and O-2p orbitals. An antiparallel spin orientation in  $VO_3$ ,  $CrO_3$ ,  $MnO_3$ ,  $FeO_3$ ,  $VO_6$ ,  $CrO_6$ , and  $MnO_6$  clusters has also been found, resulting in total magnetic moments between 1.00 and 4.00  $\mu_B$ . Meanwhile, the  $FeO_6$  cluster exhibits parallel spin

Fig. 11 Spin-polarized band structure (the Fermi level is set to 0 eV) of the  $PtS_2$  monolayer doped with (a)  $VO_6$ , (b)  $CrO_6$ , (c)  $MnO_6$ , and (d)  $FeO_6$  clusters.

ordering, resulting in a large total magnetic moment of  $5.99 \mu_B$ . Once incorporated substitutionally into the  $\text{PtS}_2$  monolayer,  $\text{TMO}_n$  clusters act as charge gainers, attracting significant charge from the host monolayer. Our study suggests that new potential spintronic 2D materials can be made from  $\text{PtS}_2$  monolayers through doping with  $\text{TMO}_n$  clusters.

## Data availability

Data related to this study are available upon reasonable request.

## Conflicts of interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

## Acknowledgements

The calculations were performed at the DGCTIC-UNAM Supercomputing Center (projects LANCAD-UNAM-DGTIC-368). D. M. Hoat expresses his gratitude for all the valuable support from Duy Tan University, which is going to celebrate its 30th anniversary of establishment (Nov. 11, 1994 – Nov. 11, 2024) towards “Integral, Sustainable and Stable Development”.
