Urea-rich porous organic polymer as a hydrogen bond catalyst for Knoevenagel condensation reaction and synthesis of 2,3-dihydroquinazolin-4(1*H*)-ones†

 Narges Zarei, Meysam Yarie, * Morteza Torabi and Mohammad Ali Zolfigol *

In this research, a new urea-rich porous organic polymer (urea-rich POP) as a hydrogen bond catalyst was synthesized *via* a solvothermal method. The physicochemical properties of the synthesized urea-rich POP were investigated by using different analyses like Fourier transform infrared (FT-IR) spectroscopy, field-emission scanning electron microscopy (FE-SEM), transmission electron microscopy (TEM), thermogravimetric analysis (TGA), derivative thermogravimetry (DTG), energy-dispersive X-ray spectroscopy (EDS), elemental mapping analysis, X-ray diffraction analysis (XRD) and Brunauer–Emmett–Teller (BET) techniques. The preparation of urea-rich POP provides an efficacious platform for designing unique hydrogen bond catalytic systems. Accordingly, urea-rich POP, due to the existence of several urea moieties as hydrogen bond sites, has excellent performance as a catalyst for the Knoevenagel condensation reaction and multi-component synthesis of 2,3-dihydroquinazolin-4(1*H*)-ones.

Introduction

Porous materials due to their prospects for performing many chemical transformations are of significant importance.^{1–3} Among the building blocks of porous materials, porous organic polymers (POPs) are the cornerstone for many research areas such as gas storage and separation, smart chemo sensors, energy storage, catalytic transformations and drug delivery.^{3–10} The bottom-up approach as a unique strategy has been used for the construction of polymeric frameworks by different linkages such as imine, boronate, hydrazone and diazonium which are synthesized from selected structural linkers and monomers.^{11–18} These advanced materials have highly ordered structures, devisable modular nature, large surface areas, tunable pore sizes and good thermal and chemical stability.^{19–21} In this respect, POPs by far are reliable and fantastic representatives for heterogeneous catalysis.²² POPs implement specific conditions to control the nature of catalytic centers. Also, these materials control the placement of surrounding surface-active sites.^{23–28} Evidently, POPs due to their ordered pore channels and excellent porosity are irreplaceable materials as hosts for guests in many catalytic reactions. Moreover, the heterogeneous nature of POP-based catalysts allows them to be easily recovered and reused after performing their catalytic activity.^{29–33}

Urea-linked POPs, as novel series of POPs, are flexible building blocks which exhibit reversible structural dynamics in their framework.³⁴ Hydrogen bond interactions and π - π stacking environments have significant effect on the conformational orientation of urea linkages which in turn affects the morphology of the target polymer.^{34–37} The mentioned items have an important impact on the catalytic activity of these unique systems. Urea-linked POPs can enhance the synergistic reaction strategy with the incorporation of two or more active sites in close proximity to activate the reactants which leads to a decrease in the activation energy barrier.³⁴ Considering the above, POPs, especially urea-linked POPs, are beneficial precursors for many catalytic transformations such as Knoevenagel condensation,³⁸ cross coupling reactions,³⁹ oxidation and reduction reactions,³⁹ asymmetric catalysis,⁴⁰ arylation reactions²⁷ CO₂ fixation,⁴¹ photocatalytic reactions⁴² and multi-component reactions.⁴³

Knoevenagel condensation, as a forefront and fundamental reaction for C=C bond formation, is an important reaction to achieving carbohydrates, fragrances, herbicides and dyes. Generally, Knoevenagel adducts are constructed by the reaction between aldehydes or ketones and compounds which contain acidic methylene bridges.^{44–47} Nonetheless, the preparation of these compounds using POPs is of great interest.^{48–50} Secondly, quinazolinone families are valuable assortment of nitrogen-containing heterocyclic compounds which are abundantly used in the pharmaceutical communities. There are several valuable marketed drugs in which quinazolinone moieties are involved.^{51–54} Numerous medicinal properties such as

anticonvulsant, anticancer, hypolipidemic, antimalarial, anti-diabetic and activities have been reported for these compounds.^{55–57}

Our initial perspective is the design and synthesis of a new urea-rich POP and it was applied as an unique heterogeneous hydrogen bond catalyst for Knoevenagel condensation reaction and synthesis of 2,3-dihydroquinazolin-4(1*H*)-ones (Schemes 1 and 2).

Results and discussion

Because of the effective role of catalysts in the chemical and industrial processes, development of catalytic systems for the organic transformations is one of the main research demands. In continuation of our investigation on the synthesis of dihydroquinolines,^{58–62} herein, we decided to synthesize a new urea-rich POP as a hydrogen bond catalyst for the Knoevenagel condensation reaction and preparation of 2,3-dihydroquinazolin-4(1*H*)-ones.

Support for the proposed chemical structure of urea-rich POP came from FT-IR analysis. In this respect, FT-IR spectra of the resulting urea-rich POP and its related starting materials were depicted in Fig. 1. FT-IR spectrum of tris(4-aminophenoxy)-1,3,5-triazine (**TAPT**) shows stretching vibrations characteristic of NH₂ groups at 3379 and 3469 cm⁻¹. The characteristic peak of C=N bonds appeared in the area of 1610 cm⁻¹. According to the FT-IR spectrum of bis(4-isocyanatophenyl)methane (**BICPM**), the sharp signal in the areas of 2263 cm⁻¹ is related to isocyanate groups. After the polymerization reaction (to give urea-rich POP), the vibrational mode of isocyanate groups of **BICPM** and NH₂ of **TAPT** disappeared. Meanwhile, appearance of a new peak at 1669 cm⁻¹, can be attributed to the amidic carbonyl groups stretching mode. In addition, signal of the amidic N–H groups has been appeared at 3339 cm⁻¹ which in turn in a strong reason for the confirmation of the successful synthesis of urea-rich POP (Fig. 1).

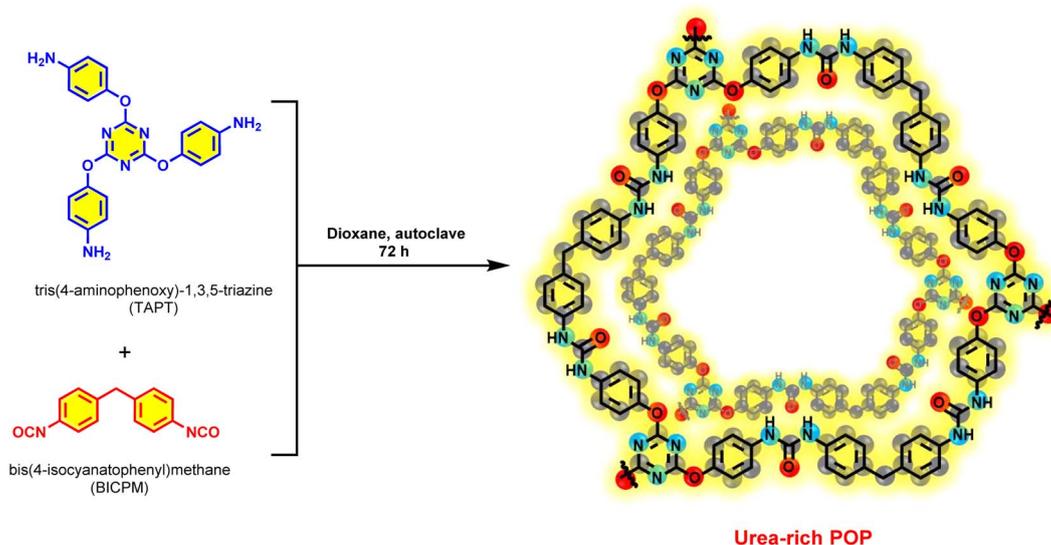

Result of the EDS analysis was confirmed the presence of C, O and N elements. Additionally, mapping analysis was used for the determination of the uniform scattering of desired elements. Elemental mapping images of urea-rich POP revealed that the N, O and C are distributed homogeneously in the urea-rich POP (Fig. 2).

In order to investigate the surface morphology of the prepared urea-rich POP, FE-SEM analysis was used. According to FE-SEM images of urea-rich POP, the porous organic polymer has a morphology of intertwined threads spheres (Fig. 3a and b). Additionally, TEM analysis has been applied to further study of urea-rich POP morphology. From the TEM images of urea-rich POP (Fig. 3c–e), it was clearly observed that the described catalyst has regular spheres stuck together containing particles with different sizes (from nanometer to micrometer).

In another study, the synthesized catalyst was characterized by nitrogen adsorption/desorption measurements at 77 K (Fig. 4a). The adsorption isotherm belongs to the type III isotherm of IUPAC classification. The appearance of hysteresis loops reveals the existence of mesopores in the synthesized catalyst. The specific surface area of urea-rich POP is 47 m² g⁻¹ which clearly shows the good porosity of urea-rich POP. Also, the pore size distribution curves, derived from BJH analysis, demonstrated that the size of most of the pores for urea-rich POP are in range of 2–30 nm (Fig. 4b), revealing the presence of mesopores.

XRD pattern illustrated that urea-rich POP has sharp signals at 21°, 29°, 36°, 39°, 43°, 47° and 49°. With more precision, the broad diffraction peak about 2θ = 21°, is attributable to the π–π stacking of the aromatic building blocks. Other sharp peaks prove that catalyst has a relatively order crystalline structure (Fig. 5).

TGA/DTG analyses as a conventional method were used for the determination of thermal stability of urea-rich POP. According to TGA/DTG curves of urea-rich POP (Fig. 6), a major weight loss occurred about at 340 °C, while a negligible weight loss was observed before this temperature and this verified the excellent thermal stability of catalyst.

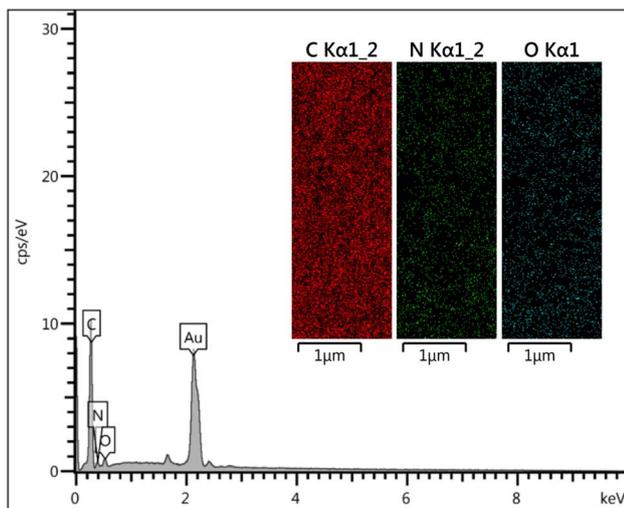

Fig. 2 EDS and elemental mapping analyses of urea-rich POP.

In the following, we have focused on the investigation of catalytic behavior of urea-rich POP as a hydrogen bond catalyst for the Knoevenagel condensation reaction and multi-component synthesis of 2,3-dihydroquinazolin-4(1*H*)-ones. In this regard, the required reactions were carried out to find the optimal conditions for the Knoevenagel condensation reaction and 2,3-dihydroquinazolin-4(1*H*)-ones synthesizing. At first, 4-hydroxy benzaldehyde and malononitrile as model substrates and urea-rich POP as a catalyst were selected for optimization of the reaction conditions for the synthesis of related Knoevenagel adduct. For exploration of the impact of temperature, the model reaction was performed at different

temperatures by using 20 mg of catalyst. The resulting data indicated that the 90 °C is the best temperature for the reaction. Then, the model reaction was performed at 90 °C in the presence of different amounts of the catalyst (10, 15 and 20 mg). The obtained data confirmed that 20 mg of catalyst is the best of choice. Also, the model reaction was done in H₂O and several organic solvents and also, solvent free conditions. It was found that the selected solvents did not provide suitable conditions for the progress of the reaction. Furthermore, the reaction was also done in the absence of catalyst under solvent free conditions, which did not progress sufficiently. Considering the obtained data, the optimal reaction conditions is where the model reaction performed under solvent free conditions by using 20 mg of catalyst at the 90 °C (Table 1). Similarly, we delve into the screening of optimal reaction conditions for the preparation of 2,3-dihydroquinazolin-4(1*H*)-ones. It was found that stirring at 100 °C by using 20 mg of urea-rich POP as a catalyst for 60 min without any solvent affords the best yield (90%) (Table 2).

The archived data from the catalytic performance of urea-rich POP in the Knoevenagel reaction and synthesis of 2,3-dihydroquinazolin-4(1*H*)-ones encouraged us to investigate the generality of the catalytic activity. In the section of Knoevenagel reaction, a series of aldehydes with different electron-deficient and electron-rich aromatic substituents were tested. Also, malononitrile, ethyl cyanoacetate and 3-(1*H*-indol-3-yl)-3-oxopropanenitrile were used as compounds which contain acidic methylene bridge. All the aldehydes and CH-acid compounds, provide the corresponding products with high yields at short reaction times (Table 3). Various aldehydes were also used for the preparation of 2,3-

Fig. 3 FE-SEM images of urea-rich POP (a and b) and TEM images of urea-rich POP (c–e).

Fig. 4 The N_2 adsorption–desorption isotherms of urea-rich POP (a) and pore size distribution curves of urea-rich POP (b).

dihydroquinazolin-4(1*H*)-ones. In this case, the synthesized derivatives had high yields and short reaction times (Table 3).

In another study, in order to find out the role of the desired catalyst, the model reactions, was checked out in the presence of urea and thiourea for comparison. The results indicated that the synthesized catalyst has the better performance. Also, due to the heterogeneity of the target catalyst, it is easily separated from the mixture of reaction and can be reused. It is worth noting that the two mentioned catalysts are homogeneous and it is not easy to separate them from the reaction mixture (Tables 4 and 5).

Besides characteristic parameters and catalytic activity, recovering and reusing of urea-rich POP as one of the influential parameters of heterogeneous catalysts was studied. To our delight, when the model reaction for Knoevenagel condensation was performed at the obtained optimum reaction conditions, the catalyst could be used at least 5 times with a negligible decreasing in catalytic activity and yield of product (Scheme 3). Hence, after accomplishing

the model reaction in each run, the mixture of reaction was dissolved in 30 mL hot EtOH while the catalyst is insoluble. Accordingly, the catalyst was easily separated by using filter paper, washed with EtOH, dried and retained for the next reaction. Also, the stability of the recovered catalyst was investigated by FT-IR spectroscopy (see ESI†).

In another exploration, we suggested a mechanistic route for the preparation of **2f** as follows. At first, ammonia derived from the dissociation of ammonium acetate attack to catalytic activated isatoic anhydride which leads to intermediate A. Then, *via* a CO_2 releasing process, intermediate A was converted to intermediate B. In the next step, aldehyde was activated by the catalyst and reacted with intermediate B to generate intermediate C. After that, the desired product was performed through an intramolecular nucleophilic attack (Scheme 4).

Experimental section

General procedure for the synthesis of urea-rich POP

Initially, TAPT was synthesized according to the previously reported methods.⁷⁷ Then, a mixture of TAPT (0.4 mmol, 0.16 g), BICPM (0.65 mmol, 0.16 g) and dioxane (6 mL) were sealed in a 25 mL Teflon lined stainless steel vessel and heated at 110 °C for 72 h. After completing the reaction, the obtained light brown precipitate

was washed three times with hot THF, MeOH and CH₂Cl₂. Finally, the obtained precipitate was dried for 12 h at 80 °C.

Conclusion

In conclusion, we have described the synthesis of novel urea-rich POP by urea linkers *via* solvothermal conditions. This polymer was precisely characterized by several techniques such as FT-IR, FE-SEM, TEM, EDS, mapping, XRD, TGA/DTG and BET techniques. Also, the catalytic behavior of the prepared structure was investigated in Knoevenagel condensation reaction and preparation of 2,3-dihydroquinazolin-4(1*H*)-ones. Plentiful hydrogen-bonding interactions of catalyst by starting materials lead to providing the activation energy of the target reactions. Most of prepared molecules have a good yields and short reaction times. In addition, recovering and reusing of urea-rich POP was studied in Knoevenagel condensation reaction and easily used at least 5 times with a negligible decreasing in catalytic activity and yield of product.

Conflicts of interest

There are no conflicts to declare.
